CONTENTS

River Gauging and Flood Prevention

THE recent floods in the Midlands, with their resultant enormous material damage and, in one or two localities, regrettable loss of life, have again directed public attention to one of the most serious and difficult problems connected with the efficient drainage of inland districts, namely, the regulation of river flow. Rivers, as a class, are notoriously erratic in their behaviour. Sometimes, in seasons of prolonged drought, they scarcely provide sufficient water for the minimum requirements of trade and agriculture ; at others, they transform themselves into raging torrents sweeping everything before them in an orgy of havoc and ruin. The control of such violent natural forces is an essential duty of civilised communities, in the interests not only of farming and transport but also of public safety. It is characteristic, however, of British methods, that, hitherto, there has been no properly organised or systematic study of the range and extent of river floods, and no national or authoritative collection of stream-flow data upon which reliance could be placed for a scientific investigation of their incidence. Certain important bodies (few in number), such as the Thames Conservancy, have carefully maintained an efficient service of river gaugings —the records at Teddington Weir are admirable— but, generally speaking, Conservancy Boards have had few or no resources available for expenditure of this kind. It is quite true, also, that, in a number of instances, individual initiative has set on foot the compilation of local data and the taking of observations which, within their limitations, are, no doubt, capable of affording much serviceable information, but these efforts are regrettably

spasmodic, and, unless carried on under supervision of unimpeachable reliability, call for careful scrutiny and independent confirmation.

As an outstanding instance of competent individual enterprise may be instanced the operations during the last few years of the private organisation known as River Flow Records, promoted by Capt. W. N. McClean, who, himself an authority on the subject, has at his own expense maintained a staff of operators to gauge and record the flow of streams in the Ness Basin, Inverness-shire. That the cost of obtaining and collating such records for public service should come out of the pockets of individuals is manifestly unfair, and, indeed, it constitutes a financial burden such as cannot generally be borne, nor, if taken up, can it be sustained for any length of time. The organisation in question was undertaken for the purpose of giving practical illustration of the manner in which gauging records of the principal water areas of Great Britain may be kept, and it has issued a series of quarterly reports giving the readings taken, with a statement of the difficulties encountered and the means by which they were overcome. New bodies, responsible for the carrying out of such duties, will do well to acquaint themselves with the methods employed in connexion with the gauging of the Ness, the Garry, and the Moriston.

Other work, of a collective nature, has been done under the auspices of the leading technical institutions, not strictly confined to the question of flood prevention, since river-flow records are essential to a number of objects: irrigation, transport, water supply, etc. The Institution of Civil Engineers in March 1931 appointed a Committee "to examine the present state of knowledge in regard to the magnitude of floods in relation to reservoir practice in Great Britain and to make recommendations on the best methods of dealing with them in that connexion". During the past twelve months, this Committee has been pursuing inquiries in order to discover the evidence available, and the information, when published, will undoubtedly be of great value. The Council of the Institution of Water Engineers, in pursuance of a resolution passed at a general meeting of the Institution in December 1927 directing attention to "the urgent need of an organisation which will ensure a continuous record of the flow and storage of surface and underground water", appointed a Committee on Stream Flow and Underground Water Records. This Committee presented its report to the annual meeting of Dec. 6, 1929, and was reappointed as another Committee on Stream Flow Gauging, authorised, if invited, to act with and assist a Governmental Department Committee on River Gauging which had been formed as a Sub-Committee to the Standing Advisory Committee on Water, comprising representatives of the Ministries of Health, Agriculture, and Transport. After sittings extending over a year, the Government Committee in the autumn of 1931 suspended or curtailed its investigations, on the ground of economy. It took the view that river gauging was a function of the new Catchment Boards set up by the Ministry of Agriculture and Fisheries under the Land Drainage Act of 1930.

Although not specifically laid down in the Act, it is obvious that a systematic determination of the range of flow in each river basin must be a primary duty of the authorities called into existence for the express purpose of coping with problems of land drainage. It is a fundamental consideration in regard to the utility of river-flow measurements that, if these are to afford reliable guidance, they must be continuous and of prolonged duration. Casual readings are quite inadequate for the preparation of plans of river improvement or control. The Committee of the Institution of Water Engineers, previously referred to, has laid it down that records should be carried on continuously for a period of between five and ten years. Most engineers with river experience will agree that the latter limit is not a day too long, and that, even then, there may be substantial variations in comparison with readings over longer periods. But, since in regard to flood prevention it is the exceptional not less than the average experience which is required, and as abnormal events occur only at long intervals, it is obvious that a much more extended range of gaugings is imperative. The memory of the oldest inhabitant of a district will often furnish instances of inundations so greatly exceeding the normal as to tax the credulity of listeners. Not infrequently, of course, there is an element of exaggeration in these recollections, such as can only be eliminated by careful and painstaking investigation. Ordinary members of Catchment Boards, without special knowledge, can scarcely be expected to appreciate the fundamental importance of continuous and prolonged as well as of precise records. It is the duty of their technical officers to emphasise these essential requirements.

A feature of the case which should not be overlooked is the change which is insensibly being brought about by the increasing extent of impervious surface, especially in urban districts, due to the rapid spread of building operations and road construction. The effect of this is to produce an

appreciable augmentation of the run-off immediately after rainfall.

Some of the forty-six new Catchment Boards, with commendable zeal, have realised their responsibilities, and have appointed special staffs to undertake the work of river survey and gauging in their areas. But this cannot be said, as yet, of the majority. It is to be hoped that lack of co-ordination of effort and uniformity of method may not render the results of variable value. As is evidenced by the earnest discussion in the House of Commons on June 15, and the pressure on the Government to provide financial assistance, flood prevention is a matter of urgent and vital importance to the community as a whole. It would be extremely unfortunate if there should be any avoidable delay in starting the preliminary investigations and any failure to pursue them on the right lines.

The Science of Peace

The Causes of War: Economic, Industrial, Racial, Religious, Scientific and Political. By Sir Arthur Salter, Sir J. Arthur Thomson, G. A. Johnston, Alfred Zimmern, C. F. Andrews, Frederick J. Libby, Henry A. Atkinson, Wickham Steed, and others. Edited by Arthur Porritt. Pp. xxix + 235. (London: Macmillan and Co., Ltd., 1932.) 7*s.* 6*d.* net.

ONE of the most significant and hopeful features in the international situation is the growing extent to which, in the last ten years, attention has been directed not merely to the prevention of war by such efforts as the scaling down of armaments and the provision of alternative methods of settling international disputes, but also to the discovery of the underlying causes of international friction and misunderstandings. This is a positive contribution to the building of a new world order, and is akin to the method of inquiry adopted in all scientific investigations. Too often in the past pacifist and politician alike have been superficial in their methods and inquiry, too eager to get a vexed problem out of the way to care whether the so-called solution or settlement was based on definitely ascertained facts impartially considered, or whether, on the contrary, it did not contain the seeds of a future and more dangerous dispute. The machinery for examining and removing the causes of war which the League of Nations has brought into being, and of which its expert committees form such an admirable example, has probably made the greatest contribution towards the establishment of what may be justly termed a science of peace.

No more authoritative discussion of the causes of war has yet appeared than that contained in the Report of Commission I. of the World Conference for International Peace through Religion. The Commission has called to its aid experts in the fields of economics, industry, racial problems, science, politics, etc., and accordingly we have an analysis of the economic causes of war from Sir Arthur Salter; the cultural causes from Prof. Arthur Zimmern, political causes by Mr. Wickham Steed. Industrial and labour influences are discussed by G. A. Johnston, racial influences by C. F. Andrews; André Siegfried contributes a section on the influence of tariffs, and Moritz Bonn one on migration.

Sir J. Arthur Thomson contributes a rather disappointing chapter on "Science and War" which will, we fear, leave many people wondering on which side scientific workers stand in this matter. It is not sufficient to plead that the blame for the use of knowledge for evil purposes lies in our imperfect human nature and not on the science which has evolved the new weapons of war. Discovery should not be blamed for the abuse of inventions based on it, but the scientific worker will be condemned by world opinion if he does not offer some contribution towards showing the way to the control of the forces his discoveries have released. Our present intolerable situation is due to a wholesale disregard of patent facts, to powerful political prejudices, to a widespread ignorance of social and economic relations in the modern world. We need, as Sir Arthur Thomson admits, a science of society, a true science of economics. It is only as scientific research and scientific methods are patiently and honestly applied in these spheres that we can develop adequate world planning of our industrial and economic resources, greater equilibrium between production and consumption and distribution—the absence of which, as both Sir Arthur Salter and Mr. G. A. Johnston insist, is a potential source of international rivalry and conflict. Similarly impartial scientific inquiry forms the only adequate basis for administration wise enough to eliminate the numerous points of friction which such matters as racial relations, religion, tariffs, migration, or national monopolies still present.

The absence of accurate knowledge in the field of racial relations and the power wielded by ignorance and prejudice are a further danger to peace, and Mr. C. F. Andrews' analysis is supported by a weighty recommendation from the Commission for the voluntary study of race relations as they affect world peace and to promote efforts to remove causes

of racial friction. In particular, an appeal is addressed to the universities to undertake a thoroughly impartial and scientific study of race relations, including anthropological, historical, and biological research, with the view of reaching generally accepted conclusions. This in itself would develop a scientific outlook on the future of the human race in reference to population. This appeal is further supported by a statement from Dr. Rabindranath Tagore, who asserts that this great evil of racial prejudice is only to be overcome by the dissemination of accurate scientific knowledge, and that research in the universities and its interpretation to the world by unimpeachable authority is our most vital need.

Honestly applied in these fields, the scientific method may yet prove mightier than the forces released by the prostitution to destructive purposes of its achievements in the mechanical or physical world during the last half-century. Even in the political sphere, accurate knowledge upon international matters, as Mr. H. Wickham Steed points out, is a prime desideratum, and its accumulation and dissemination as the practice of fact-finding in concert or the technique of conference develops should avail to exorcise the spirit of fear or insecurity and distrust which are foremost among the political causes of war. Certain it is that the dispassionate analysis of the causes of war and their appraisement apart from prejudice in the light of reason afford the only method by which wise preventive measures can be evolved and knowledge regain control. It is at least possible that in this field also the calm, serious spirit of science may prove victorious once more, as in the past it has emancipated mankind from the fetters of superstition and ignorance in the fields of religion and disease.

Laboratory Construction

Laboratories: their Planning and Fittings. By Alan E. Munby. With an Historical Introduction by the late Sir Arthur E. Shipley. Second edition. Pp. xix + 224. (London: G. Bell and Sons, Ltd., 1931.) 30*s.* net.

THE first edition of this work was published in 1926, and the second edition follows on similar lines. The section dealing with the needs of biology and geology has been enlarged by twenty pages, and the last section, consisting of a number of plans of recently built laboratories, has been revised; as before, it contains a number of school laboratories, including those at Clifton, Highgate, and Beaumont, and a number of university laboratories, for both physical and biological sciences. The Los Angeles Normal School laboratories, although included in the school section, would seem more properly to be placed in the university division.

The author in his preface says that "there is still no consensus of opinion among scientists as to what the material equipment in fittings and services should be for a given subject, nor has the author succeeded in raising any general interest in this topic". This is scarcely surprising, for every laboratory is in itself something of an experiment. It falls to the lot of but few people to be concerned with the building of more than one or two laboratories, and these have in general to modify their desires, to bring the cost within the limits of the available resources. Nearly every teacher has suffered in the past from some architectural difficulty in his laboratories, and he is usually mainly concerned to avoid the ills of which he knows, often to produce for himself others unforeseen. There is no common pool of experience. Mr. Munby's book is welcome as an attempt to provide something of the sort. For this reason, one might wish that he had dealt more critically with the design of the laboratories which he has given us. A single example will serve to illustrate this point. In Sir Arthur Shipley's pleasant introduction, a plea is, most rightly, made for more intelligent consideration as to the relative position of the lantern and the screen. For ordinary day-to-day routine work the only place for the lantern is on the lecture bench itself, where the teacher, in whatever institution, may be able almost to operate the lantern with one hand and write on the board with the other. Why is it, therefore, that architects almost always contrive to place a window opposite one end of the lecture bench and a door opposite the other? In the Clifton lecture rooms this error has been avoided, but it would be interesting to know whether, in some of the other lecture rooms shown, the architectural arrangements have operated to prevent proper use being made of the lantern.

In some of the school laboratories shown, part of the space is taken up by desks and part by the usual laboratory furniture. The effect of this seems definitely to be a waste of fifty per cent of the room at one time or another. A critical account of how each laboratory is found in practice to fulfil its aims might help to develop that consensus of opinion which is so slow in developing.

In the body of the work it is at times a little difficult, when the author is dealing with general questions, to know whether he has in mind university or school conditions. The schedule of rooms for definite subjects rather suggests that he holds

the view that school science laboratories should be built on much the same lines as those of the universities, with the omission of some of the specialist rooms. It is difficult to agree with this view, and the recent tendency to build school laboratories on rather an elaborate plan, with expensive fittings, is to be deprecated. One could wish that the author would give us a critical analysis of the essential needs of schools, as distinct from universities, with examples of the way in which these have been successfully met. A few examples as to the difference between schools and universities may be mentioned. The 'top hamper' of the university chemical benches for bottles used in qualitative analysis has no place in schools to-day. Nor are the cupboards under the benches so necessary, except perhaps at the post School Certificate stage. At Rugby, for example, neither drawers nor cupboards are provided in the benches for elementary chemistry. The spaces are there, but they are unenclosed and the contents always open to view. The simplification reduces initial cost, makes supervision simpler and cleaning easier. It is also more than doubtful if in elementary chemical laboratories for schools a special balance room is needed. The conduct of practical work is easier and the costs are reduced if the balances are kept in the laboratory itself.

One of the difficulties under which teachers often labour is that they cannot make full use of the wall space and of the ceiling of their laboratories. Frequently the walls are broken up by the windows, which have been designed more with the view of providing an attractive elevation than with providing what the science teacher needs. Again, they are often plastered and it is sometimes difficult for an active-minded science teacher to fasten to the walls such apparatus as he may from time to time desire to put up. Is there any reason why laboratory walls should be plastered at all? The Cavendish Laboratory stands as an admirable model in its simplicity and effectiveness, and its walls are unplastered. Similarly, more use could be made of the ceiling if suspension beams, such as are suggested in the Board of Education's recent pamphlet on "Secondary School Buildings", were used.

The book contains a useful chapter on laboratory services, but the section dealing with electricity is not adequate to the importance of the subject. The legends under Figs. 64 and 65 have obviously become interchanged.

In some instances the author quotes costs, but these all seem to be higher than is necessary if efficiency only is to be considered. At Beaumont it worked out at 1*s.* 9½*d.* per cubic foot, at Clifton 2*s.*, and at Highgate 2*s.* 1*d.* Special circumstances doubtless account for these, but it would not be difficult to show excellent science buildings costing only 1*s.* 4½*d.* per cubic foot. The cost of fittings must vary with the size of the school and the number of laboratories. At Beaumont it was £2900, at Highgate £5563, and at Clifton £7000. For a school of 400-500 boys, four laboratories and a lecture room, with ancillary rooms, ought with reasonable care to be provided with the mere furniture for something like £1500. In these times of financial stress, those about to build laboratories should not therefore feel unduly despondent if the figures given by the author seem beyond their resources.

Life and Logic

(1) *The Emergence of Life: being a Treatise on Mathematical Philosophy and Symbolic Logic by which a New Theory of Space and Time is Evolved.* By John Butler Burke. Pp. ix + 396. (London: Oxford University Press, 1931.) 30*s.* net.

(2) *The Mystery of Life.* By John Butler Burke. (The Library of New Ideas, No. 5. Pp. 160. (London: Elkin Mathews and Marrot, Ltd., 1931.) 3*s.* 6*d.* net.

WHEN one leans over the infinite, speech appears a rather embarrassing means of conveying to others the volcanic impetus of one's intuitions. Yet, is it not a privilege of the philosopher to attempt a faithful translation of this unique experience? So long as he respects the steady parallelism between facts and their expression, he is allowed to enlist the help of analogy and mathematical symbolism in his errand of spiritual charity. But woe to him if he yields to the charm of his endeavours, and allows himself to be carried by his symbols further than the brutal facts permit. Though he need not fear a violent end as a reward for his exaggerations, he may be liable to suffer the more dreadful penalty of seeing his theories universally dismissed as being castles in the air.

Mr. Burke has taken considerable risks in leaning over the infinite and in trying to record for us the impressions of his vision. During twenty years he has had time to ponder over the maze of difficulties set to human wit by matter, life, and mind; and now he has the courage of proclaiming to the world the solution of the discouraging puzzles invented by the rational genius of the Greeks. Mr. Burke has already made a first attempt, in 1906, when he proposed the view, in his "Origin of Life", that

some kind of living organism is the primordial element, and that inanimate matter is only the result of the decay of living matter. But he was not satisfied himself with the purely experimental side of his theory, and now he comes back to it armed with the compelling weapons of mathematical logic and symbolism. His fundamental method is the application of Leibniz's ideal of a 'universal characteristic', as actualised by Boole's logical algebra, to Hegel's metaphysics; with the result that he obtains a more complex Leibnizianism which suggests also a novel interpretation of Plato's central theory of ideas. The most notable extension of Leibniz's system is that Mr. Burke rejects the principle of pre-established harmony, and explains the interaction between the monads by what he calls 'time-waves' or scintillation of groups of monads in time, which account for the phenomena of living matter, its growth, reproduction, and hereditary transmission.

Mr. Burke emphatically declares that there is not substance but mind. Following Ostwald, who had already destroyed matter for the benefit of energy centred in points in space, he carries these centres of energy further: so they become centres of mind-stuff, or ideas potentially or actually self-conscious, and, in the limit, ideas in that Mind which conceives and animates it all. These self-conscious units or monads are realities apparently independent of each other. The evolution of life and mind from 'so-called' inorganic matter, in the remote past, is then reconciled with the theory that physical and chemical atoms are systems of such monads. Among these 'atoms' Mr. Burke allows a certain amount of natural selection, illustrated by the survival of stable forms or groups, or the sifting of those types which can manifest and propagate in an efficient manner the characteristic properties of life. The vital principle in organic and inorganic matter is then to be sought in this variation in the atoms of the organism.

The manner in which such variation may arise and be followed up—that is, the evolution of the nebular and spiral atoms in the various stages of condensation, from the primordial substance of mind-stuff to the structure of highly developed mind—is explained in great detail in "The Emergence of Life", after an interesting discussion of the necessary logical and methodological prolegomena, such as algebraic analysis, existential propositions, certainty and probability, induction and analogy. "The Mystery of Life" gives an interesting summary of these views, with some additional comments on their philosophical bearings.

The question whether Mr. Burke's stimulating views carry with them a universal conviction will have to be left open. There is no doubt, however, that they deserve a careful study, in so far as they indicate a possible method of approach to the problems of matter, life, and mind. Though he makes a legitimate use of mathematics and logical symbolism, his analogies seem to be sometimes far-fetched, as, for example, when he suggests that the conjunction of two imaginary notions may yield a real idea, as is the case with two complex numbers. But perhaps this difficulty is due to the fact that the metaphysical interpretation of the complex numbers and their operations is not yet definitely settled. Again, one might be tempted to dispute the truth of Mr. Burke's initial principle that the primordial substance accounts by itself for the existence and evolution of matter, organic and inorganic. Even a matter of years could not show us whether this dogmatic assertion is an arbitrary assumption or not. But here the wider ground of speculative philosophy is safer for Mr. Burke than that of natural philosophy with its restrictions in space and time; for, as he says himself, if life on earth will last for yet a thousand million years, it is not unlikely that man may yet realise the purpose of his existence, while memory holds a seat in this distracted globe. We may outlive our present knowledge in beauty, in growth, and in strength, in worlds more real though now unknown, but not unknowable in the æons that are yet to come. T. GREENWOOD.

Agriculture and National Prosperity

Fertilizers and Food Production on Arable and Grass Land. By Sir Frederick Keeble. Pp. xi + 196. (London: Oxford University Press, 1932.) 5*s*. net.

THE nation is at least alive to the deplorable plight of the agricultural industry in Great Britain. This awareness is undoubtedly penetrating deeply, and there is a growing desire to be informed as to the facts—and the facts of agriculture are singularly intricate and involved. The hard truth, however, remains, that a sound agricultural policy can only be built with bricks and mortar that have themselves been constructed by capable workmen possessed of the necessary knowledge.

To marshal an immense amount of information fundamental to a proper understanding of the agricultural potentialities of Great Britain, and to weld the evidence from innumerable experiments and extensive trials into a concrete and highly sug-

gestive story of less than 200 pages, is indeed a signal achievement. This is what Sir Frederick Keeble has accomplished in the little book before us. It is true that Sir Frederick is here only concerned with the production aspect of the general problem. What does the country produce ? And what could the country produce ? These are the questions which in effect Sir Frederick has set himself to answer. In the last resort, however, policy must be based on sound economic production, and to-day sound economic production must to a very large degree be determined by the skill with which artificial fertilisers are employed.

There is no gainsaying that the farmers of Great Britain as a whole are not making a sufficiently abundant or a sufficiently well-informed use of fertilisers. Thus, as Sir Frederick pointedly remarks, although the acreage under pasturage has been considerably increased during the past sixty years, the grasslands of the country are carrying few if any more live stock. Indeed, the picture which Sir Frederick is compelled to paint in the opening chapters of his book is a sombre one: thousands upon thousands of acres needing drainage, scores upon scores of fields without facilities for watering, and whole districts in need of lime. It is, however, when the results of experiments and records are considered that we are made to realise that the present gloom and depression is by no means inexorable. In dealing with experimental evidence, Sir Frederick Keeble has in the main confined himself to the results obtained from the extensive investigations undertaken at the Jealott's Hill Agricultural Research Station and from the trials conducted in the counties and overseas under the auspices of the research staff of the Station.

All this research is of itself of great intrinsic importance, and has an added value not only because it has been unusually far-flung, but also because it has been conducted with absolutely definite economic ends in view, and the whole undertaking has been in no wise hindered by undue adherence to orthodox opinions. It is stimulating and suggestive to find the problem of the soil and of fertility being dealt with essentially from the biological point of view. "Crop, soil and soil micro-organisms", Sir Frederick insists, "must need be investigated simultaneously," and with characteristic vision he adds, "a great task fraught with great issues for the welfare of mankind."

As is only to be expected in the case of a book dealing with such a wide range of issues and with the interpretation to be put on so large a number of inter-related phenomena, there are points of detail concerning which we might join issue with the author; points which for the most part, however, are still under investigation both at Jealott's Hill and elsewhere. It is probable, for example, that less than justice is done to ordinary moderate grassland which is reasonably well managed and which has a high clover content. Thus in Chart III., on p. 43, comparison is made between the "oat crop", "ordinary grass cut for hay", and "intensive pasture grass". Certain types of clovery pasture, although more or less extensively managed, would of course stand comparison with the "intensive" grass altogether better than would "ordinary grass cut for hay". The virtues of clovery grass are not, however, ignored, and the suggestions made for the rotational (in the annual sense) cropping of grassland (pp. 121-124) are of the highest importance and of far-reaching significance.

The value of the book is much enhanced by the excellent charts, abundant and well-arranged tables, and carefully prepared appendixes.

Short Reviews

Fundamental Experiments in Chemistry: a Handbook for Teachers and Students; Lecture and Class Experiments to establish Chemical Laws and to confirm the Atomic Theory. By E. D. Goddard. Pp. xii + 147. (London: Ginn and Co., Ltd., n.d.) 3*s*. 6*d*.

THIS little handbook, evidently the outcome of long experience in teaching young students, is primarily intended for science masters in secondary schools. It includes a well-selected and well-arranged collection of lecture and class experiments designed to establish the laws of chemistry and to confirm the atomic theory. By actually doing some of these and having others demonstrated to them, students should obtain a clearer conception of the fundamentals of chemistry than they could derive from a mere recitation of the evidence adduced by the pioneers and the more recent advances by later research workers.

The author gives a description of the experiments and methods he has found successful in presenting such matters as the density of gases and the volume composition of water, hydrogen chloride, ammonia, the oxides of carbon, nitrous oxide, and ozone to classes of boys. Appended to each experiment is a series of notes giving special hints and indicating necessary precautions or variations that are admissible. Another valuable feature of the book is that the results actually obtained by the students themselves are used as examples to illustrate the experiments and the working out of the results. Like the author, the reviewer has found it a good plan to summarise all the results of the students, since, at the conclusion, they are invited to indicate which results should be omitted when the average result

is being found. It is remarkable that the average result for the whole class is usually surprisingly near to the correct one.

Science masters and others will find Mr. Goddard's book useful, if only on account of the number of interesting little points and suggestions he makes in connexion with each experiment. J. G. F. D.

Handbuch der physikalischen und technischen Mechanik. Herausgegeben von Prof. Dr. F. Auerbach und Prof. Dr. W. Hort. Band 1: *Technische und physikalische Mechanik starrer Systeme,* Teil 1. Lieferung 1. Pp. ix + 306. Lieferung 2. Pp. viii + 307-694. Lieferung 3. Pp. 695-787 + xviii. Band 1, vollständig, 80 gold marks. Band 2: *Technische und physikalische Mechanik starrer Systeme,* Teil 2. Lieferung 1. Pp. viii + 404. Lieferung 2. Pp. xiv + 405-673. Band 2, vollständig, 75 gold marks. (Leipzig: Johann Ambrosius Barth, 1927–1930.)

DURING the years 1890 to 1896 Winkelmann published a famous handbook on physics, which reappeared in a new edition in the years 1901 to 1909. When, about six years ago, a third edition was called for, the growth of material to be treated led to the division of the single handbook into a series of handbooks, each dealing with different domains, under separate editors. Among their subjects are electricity and magnetism, physical optics, and mechanics (physical and technical). The last of these, which is the subject of this brief notice, comprises seven volumes, some of them divided into parts separately published (these cannot be separately purchased, each volume being sold as a whole). Some part of each volume has appeared, and some volumes, but not all, are complete. The work is remarkable in its scope, and is well printed and illustrated. Probably few individual teachers or students could afford to possess a copy of so large a work, which is necessarily expensive, but in scientific libraries, whether academic or industrial, it deserves a place. Its great merit is that it brings together, in an easily accessible and assimilable form, a large body of scattered knowledge on mechanics, together with references to sources of fuller information. The first two volumes deal with the general principles and main results in kinematics, dynamics and statics, and mechanism, and conclude with an interesting account of physiological (including human) mechanics and mechanism.

The Mysterious Universe. By Sir James Jeans. Second edition. Pp. ix + 142 + 2 plates. (Cambridge: At the University Press, 1931.) 2*s*. net.

IN the second edition of this well-known book, the author explains that he has found with regret that certain passages in the original book were liable to be misunderstood, misinterpreted, and even misquoted, in various unexpected ways. He has expunged some of these passages and re-written or amplified others. Here and there new paragraphs, occasionally even whole passages, have been added in the hope of making the argument clearer. The main line of thought, however, is unchanged, and needs no comment. The opportunity has also been taken of correcting certain misprints and errors in the first edition. It is a pity that this was not carried out more thoroughly. We still have, for example, the ambiguous "this" on p. 38, line 11; the miscalculation on p. 84; the singular noun and plural verb at the top of p. 134; and the statement (p. 49) that Maxwell had "shewn" (instead of "predicted") and Lebedew had "measured" (instead of "observed") the pressure of radiation. One of the newly introduced paragraphs, in fact, contains the misstatement (p. 119) that Kepler believed in the truth of his "five solids" law "for one brief moment". Criticism of details to the neglect of the whole is admittedly reprehensible, but insufficient care in verifying details, especially in a second edition, is nevertheless to be regretted. The paper and printing of the new edition are in no way inferior to those of the old, despite the reduction in price.

Dimensional Analysis. By Prof. P. W. Bridgman. Revised edition. Pp. vi + 113. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1931.) 24*s*. net.

THE second edition of Prof. Bridgman's well-known book differs very little from the first. A few minor errors are corrected, and references are given to the writings of certain other authors that have appeared in the interval. Though these are strongly critical of Prof. Bridgman's doctrines, he sees no reason to change his opinions; he prefers, therefore, not to enter into controversy, but to leave his readers to judge between him and his critics. This procedure is entirely creditable to Prof. Bridgman, and certainly preferable to an attempt to expound views with which he has no sympathy. But the whole position is not creditable to science. The differences that divide Prof. Bridgman from his critics are not matters of opinion; they concern the validity of certain quite simple logical arguments; one side in the dispute must be definitely right and the other definitely wrong. Let us hope that the appearance of this reprint will encourage impartial examination of the controversy and lead to the final establishment of the truth. N. R. C.

Quanta et chimie. Par Prof. Arthur Haas. Traduit de l'allemand par Jeanne Perrenot et F. Esclangon. Pp. v + 69. (Paris: Gauthier-Villars et Cie, 1931.) 15 francs.

THE scope of this little work, based on four lectures, is, as explained in the author's preface, to present, as simply and shortly as possible, quantum physical theory having an interest to chemists, and avoiding any use of mathematics. As the limitations imposed by these conditions indicate, the book is a résumé of the position (in 1929), popular only to the extent of being written for the non-specialising scientific worker. The four chapters deal with the arithmetic of chemical periodicity, the quantum theory of valency and chemical forces, electron grouping and the periodic system, and the quantum problem of molecular and nuclear structure. An English version has appeared under the title of "Quantum Chemistry". N. M. B.

World Structure and the Expansion of the Universe*

By Prof. E. A. MILNE, F.R.S.

THE most distant nebulæ appear to be receding from us, and the velocity of recession is proportional to the distance. The most commonly accepted explanation of this phenomenon is that due to Friedman and Lemaître. The principle of their explanation is that it is possible to describe the observed facts by assigning fixed co-ordinates to a distant nebula in a curved space-time in which the metric involves the time t. The spatial interval-distance between the nebula and the observer is then a function of t. The difficulties of this explanation are (1) that it involves the existence of 'cosmic time' and restores the distinction between time and space abolished by Minkowski; (2) that it has been impossible to explain why 'space' is expanding and not contracting. This theory is a development of the remarkable pioneer theories of Einstein and de Sitter, which contemplated static metrics for space-time. De Sitter's world, it is true, placed time on the same footing as space, but Einstein's cylindrical world introduced "cosmic time". More recently (*Proc. Nat. Acad. Sci.*, **18**, 213; 1932), Einstein and de Sitter have concluded that at the present moment it is impossible to determine the algebraic sign of the curvature of 'space', and that the facts of observation can be described by assigning fixed co-ordinates to a distant nebula in a quasi-Euclidean space expanding with the time.

A much simpler explanation of the facts may be obtained as follows. The explanation abandons the curvature of space and the notion of expanding space, and regards the observed motions of distant nebulæ as their actual motions in Euclidean space.

Consider a spherical region of Euclidean space, occupied at time $t=0$ by a uniform spatial distribution of moving particles, moving in random directions with velocities u, v, w, distributed according to a law $f(u, v, w)\, du\, dv\, dw$. The density is supposed to be so small that collisions do not occur and forces of interaction are supposed negligible. Outside the sphere (say of radius r_0) let space be empty. Then the *outward* moving particles will move into the empty space outside and the faster particles will gain on the slower. At any time t the fastest moving particles will form an expanding spherical frontier, followed by the next fastest, and so on. The *inward* moving particles will traverse the sphere of radius r_0, emerge at the other side, and then move outwards. Thus at any sufficiently large time t all the particles moving with a given speed V will be found between the spheres of radii $Vt-r_0$ and $Vt+r_0$. We see at once that after the lapse of sufficient time, all the distant particles will have velocities of recession; and the mean velocity of recession at any distant point will be ultimately proportional to the distance, the constant of proportionality being simply $1/t$. The interior of the original sphere, and indeed all space inside the distant moving portion, remain occupied throughout. For example, near the centre of the original sphere, after a long time t only slow-moving particles will be found, namely, those which started inwards from the original frontier with sufficiently small velocities. The density everywhere decreases with the time, and the particles sort themselves out in velocity, the sorting becoming more perfect the larger the velocity.

Clearly the restriction to an initially uniformly occupied sphere is unnecessary. Any initial density distribution which decreases sufficiently rapidly with distance will give rise to the same effect. This is true even if the initial distribution fills infinite space. The only difference is that *every* small element of volume always contains a few slow-moving particles, even after a long time; but the sorting goes on. The essential aspect of the situation is that we are dealing with an unenclosed system.

The above explanation is applicable at once to the system of nebulæ. The fastest moving ones will have velocities exceeding the velocity of escape against gravity, and will ultimately pursue curves indistinguishable from their linear asymptotes.

This common-sense explanation has many advantages in addition to that of rendering unnecessary the introduction of a curved 'space' and a non-static metric. It shows at once that the system is necessarily an expanding system after a sufficiently long time. If at any instant all the velocities are imagined to be reversed in direction, the system appears to contract to its configuration at time $t=0$ and then expands again. Moreover, if at time $t=0$ all the velocities are reversed, the system still expands. The instant $t=0$ affords a natural origin of time for the observer recording the distribution-laws. From this instant evolution proceeds in an inevitable direction, namely, in the direction of expansion. We may say that creation and uni-directional evolution are brought into a single mathematical scheme.

It is quite unnecessary, however, to introduce a 'cosmic time'. Let an observer count the particles with velocities inside the range u to $u+du$, v to $v+dv$, w to $w+dw$, and arrive at the law $f(u, v, w)\, du\, dv\, dw$. Let a second observer, moving with uniform velocity V_0 with respect to the first, make a similar enumeration, and suppose he arrives at the law $f_1(u, v, w)\, du\, dv\, dw$. We may inquire what must be the actual distribution-law in any frame so that $f\equiv f_1$, that is, so that the velocity-pictures of the universe recorded by the two observers are identical. Neglecting the curvatures

* Synopsis of a paper read at a colloquium at Wadham College, Oxford, on June 7, 1932.

of the paths, we find that the distribution-law must be

$$\frac{B\, c\, du\, dv\, dw}{(c^2 - u^2 - v^2 - w^2)^2}$$

where B is a pure number and c is the velocity of light. This permits a continuous distribution of velocities up to c. Since actual recession speeds have been recorded up to one-fifteenth of that of light (19,700 km./sec., see Humason, *Mt. Wilson Contributions*, No. 426, 1931), and since still higher velocities may be expected, there seems nothing fantastic about this distribution-law.

Suppose now two observers start at the centre $x=0$, $y=0$, $z=0$ of the initial spherically symmetrical distribution at time $t=0$, with relative velocity V_0 with respect to one another. We may inquire what must be the spatial distribution of particles such that the universe will for ever appear the same to each observer. This requires a more complicated analysis, for the two observers will disagree as to what is meant by simultaneity. To solve this problem it is necessary to introduce the concept of the intensity I of world-lines at a point in time-space in a given direction. This is defined as the number of world-lines per unit solid angle in 4-space per unit 3-space cross section normal to the direction of the world lines. The conditions that any proposed function $I = F(x, y, z, u, v, w, t)$ shall represent a concourse of permanent objects are that (1) F shall be invariant for a Lorentz transformation, (2) F shall be constant along a world-line; the second condition is readily shown to be equivalent to the satisfaction of Boltzmann's equation in gas-kinetic theory. When F is determined and we return to the co-ordinates x, y, z, t of any particular observer measured from the natural origin of time-space, the distribution law is found to be

$$\frac{c^2 A\, du\, dv\, dw\, dx\, dy\, dz}{(c^2 - \Sigma u^2)[(c^2t - \Sigma ux)^2 - (c^2t^2 - \Sigma x^2)(c^2 - \Sigma u^2)]^{\frac{3}{2}}}$$

which may also be written in the form

$$\frac{c^2 A\, du\, dv\, dw\, dx\, dy\, dz}{(c^2 - \Sigma u^2)[c^2\Sigma(x - ut)^2 - \Sigma\{v(z - wt) - w(y - vt)\}^2]^{\frac{3}{2}}}$$

This shows at once that for given $x^2 + y^2 + z^2$ and given $u^2 + v^2 + w^2$, the density is a maximum (for sufficiently large t) when $u : v : w = x : y : z$, that is, it gives the recession predominance. It also gives the velocity-distance correlation for t large. Integrated over the complete spatial solid-angle for 3-space it gives for time $t=0$ the distribution-law

$$\frac{4\pi c\, A\, du\, dv\, dw}{(c^2 - \Sigma u^2)^2} \cdot \frac{dr}{r}$$

showing that the density-distribution at any time t may be derived as the natural expansion of an initial distribution * with a density law $\rho \propto 1/r^3$. This of course gives a congestion of matter at the origin at time $t=0$, and expanding spheres of singularities at any other time. This in turn shows that it is necessary to introduce gravitation and so curvature of world-lines as a second approximation. But the density law $\rho \propto 1/r^3$ gives a gravitational potential tending to a constant at large distances, and so preserves the analysis as representing the uniform rectilinear motions at great distances. Presumably a Gaussian metric is required for the vicinity of the space-time origin, but it tends to the Galileian form at great distances.

According to these very elementary considerations, which only involve the principles of the special theory of relativity, the continuum of time-space is occupied at large distances from the natural space-time origin by a hyper-complex of world-lines having spherical symmetry about the space-time origin. There is no such thing as cosmic time. But at each point of space-time there is a unique direction in which the space-time origin lies. Every observer sees the same velocity distribution at great distances. Every observer can regard himself as the centre of the universe by choosing his time axis so as to point away from the time-space origin—in other words, by choosing the motion of his frame of reference so that it is at rest with respect to the vector average of the motions in his immediate neighbourhood. The world is then perfectly ego-centric at all points, and the moving picture of the world as made by any one observer is identical with that made by any other observer.

The principle of relativity in its original form asserted that all frames of reference are equivalent for the description of the *laws* of Nature. The foregoing ideas rest on an extension of the principle to the assertion that the world itself, when local irregularities are disregarded, must appear to have the same structure to all observers; in other words, the principle of relativity is extended from the *laws* of Nature to the *phenomena* occurring in Nature.

We cannot observe space. We observe point-events. But we can recognise the continued existence of material objects, and hence we can arrange these observed point-events in world-lines. It seems best to avoid the phrase 'the structure of space' or of 'space-time', and consider simply the structure of the hyper-complex of world-lines which can be reconstructed from our observations. The preceding analysis discusses the simplest ideal system of world-lines that is compatible with the observed permanence of material objects and satisfies the extended principle of relativity. It is not difficult to generalise the analysis so as to describe a hyper-complex of curved world-lines and to connect the distribution of intensity with the distribution of curvature, and thus to make some progress towards the introduction of gravitation even inside the limits of Galileian space-time. But these developments are deferred to another occasion. I conclude by emphasising the very simple explanation of the expansion of the universe of material objects obtained by examining the kinematics of an unenclosed system with central condensation.

* For $t=0$, the last formula gives the distribution *between* the radii r and $r+dr$. But at $t=0$, at any given *point* r, the velocities are predominantly tangential.

Three Arctic Expeditions in 1931

IN the summer of 1931, three expeditions using very different equipment visited adjacent regions of the arctic, and Prof. H. U. Sverdrup has summarised the preliminary results obtained and compared the usefulness and prospects of the different methods employed.* The Swedish-Norwegian party under the leadership of Prof. H. W:son Ahlmann relied upon the old proved technique and carried out oceanographical work from the *Quest* in the neighbourhood of Franz Josef Land and Spitsbergen (North-East Land) together with dog and sledge journeys across North-East Land, which was shown not to be covered with a continuous ice sheet as formerly believed, but to be divided into two ice areas by a broad ice-free valley. Large geological and botanical collections were made, and the study of these and of the meteorological and oceanographical observations is proceeding.

The other expeditions with submarine and airship were financed by the Press, and for this reason and on account of the novel means employed, they received wide publicity. An American Press magnate who was interested in Wilkins's submarine (*Nautilus*) project had offered to finance the Zeppelin flight on the understanding that the air-ship should attempt to establish contact with the submarine near the north pole, but when the *Nautilus* was delayed by an unlucky Atlantic crossing, this plan had to be abandoned and the support for the flight was not forthcoming. Fortunately the commander, Dr. Eckener, was able to come to a favourable understanding with the German Press, and although the original plans developed by Nansen of a flight across the pole could not be entertained, a cruise to Franz Josef Land and to Nicholas II. Land off northern Siberia was successfully accomplished.

The Zeppelin trip from Leningrad only occupied four days. At Franz Josef Land the airship descended to the water and exchanged mails with the Russian ice-breaker *Malgyin*, and this—the first 'landing' to be made without ground parties—demonstrated the usefulness of the ship as a transport vessel to uninhabited regions. One of the unknown dangers of the expedition was the possibility that ice would be precipitated from the clouds on to the great envelope of the airship and force it down, but this was not realised, because throughout the cruise the temperature of the air passed through was above 0° C., being higher at 1000 m. than at the earth's surface. This temperature inversion, well known to exist in winter, Prof. Sverdrup thinks, may not always obtain in summer, and he anticipates different conditions in the Atlantic quadrant of the polar area from those over the Siberian and Alaskan quadrants, and issues a warning against generalising from this limited experience.

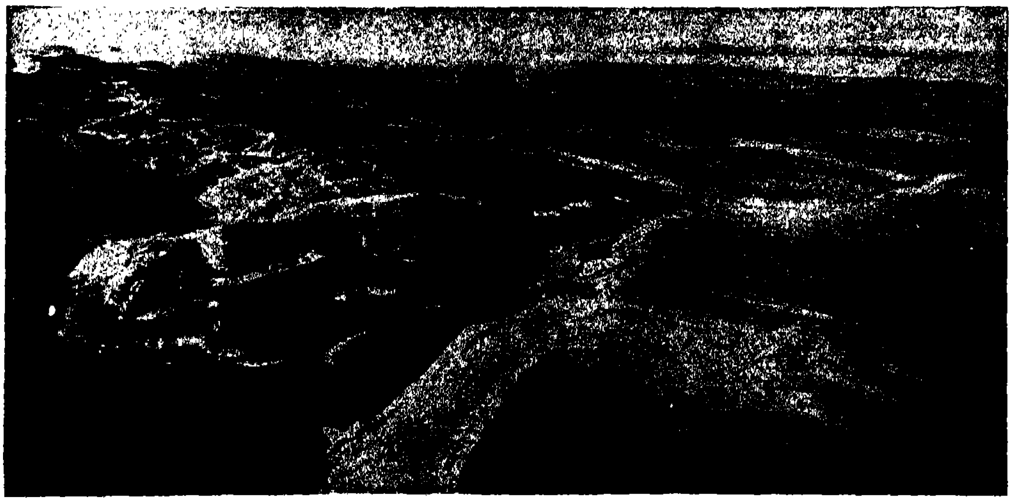

FIG. 1.—Panorama of the Taimyr Peninsula. The shadow of the *Graf Zeppelin* is seen near the middle of the right half of the picture.

For the first time, radio *ballons-sondes* devised by the Russian meteorologist Moltschanof were used to obtain observations of the upper atmosphere. These balloons are equipped with small radio-transmitters sending out signals from which temperature and humidity values are obtained for different altitudes, thus furnishing instantaneous records in regions where there is little hope of the recovery of instruments. Four balloons were dispatched, of which three reached an altitude of more than 16 km., and it was found that at about lat. 80° the temperature of the stratosphere (with its base at 10·4 km.) was −50° C. In summer the average height of the stratosphere in Europe is 11 km. The *Maud* expedition in the spring months obtained a value of 8·5 km. north of Siberia, and Prof. Sverdrup suggests that whereas in general the

* *Nature*, 1932, p. 86.

height of the stratosphere falls off from the equator to the pole, its minimum altitude, which may be styled the meteorological north pole, does not coincide with the geographical pole but lies between it and Siberia and Alaska. Photographs were taken which will be of assistance in improving the maps of Novaya Zemlya and Franz Josef Land, and it was discovered that Nicholas II. Land is divided into two by a broad strait which has now been mapped on the ground by the Russian geologist, N. N. Ourvantzev.

The good fortune which followed the Ahlmann and Eckener expeditions was denied to Wilkins's submarine venture, in which Prof. Sverdrup himself took part. On reaching the pack ice north of Spitsbergen, it was found impossible to dive, on account of the loss of the vertical rudder: the main project—to test the feasibility of navigation under the ice—was unfulfilled, and instead of a submarine the explorers found themselves in a ship very unfitted for ice work. Nevertheless, a large number of echo soundings and a series of gravity measurements were made, oceanographic stations established, and bottom samples brought up from depths down to 3500 m. From the character of the deeper water, further evidence was obtained in support of Nansen's deduction that the submarine ridge trending northwest from Spitsbergen descends to 1500 m. between Spitsbergen and Greenland.

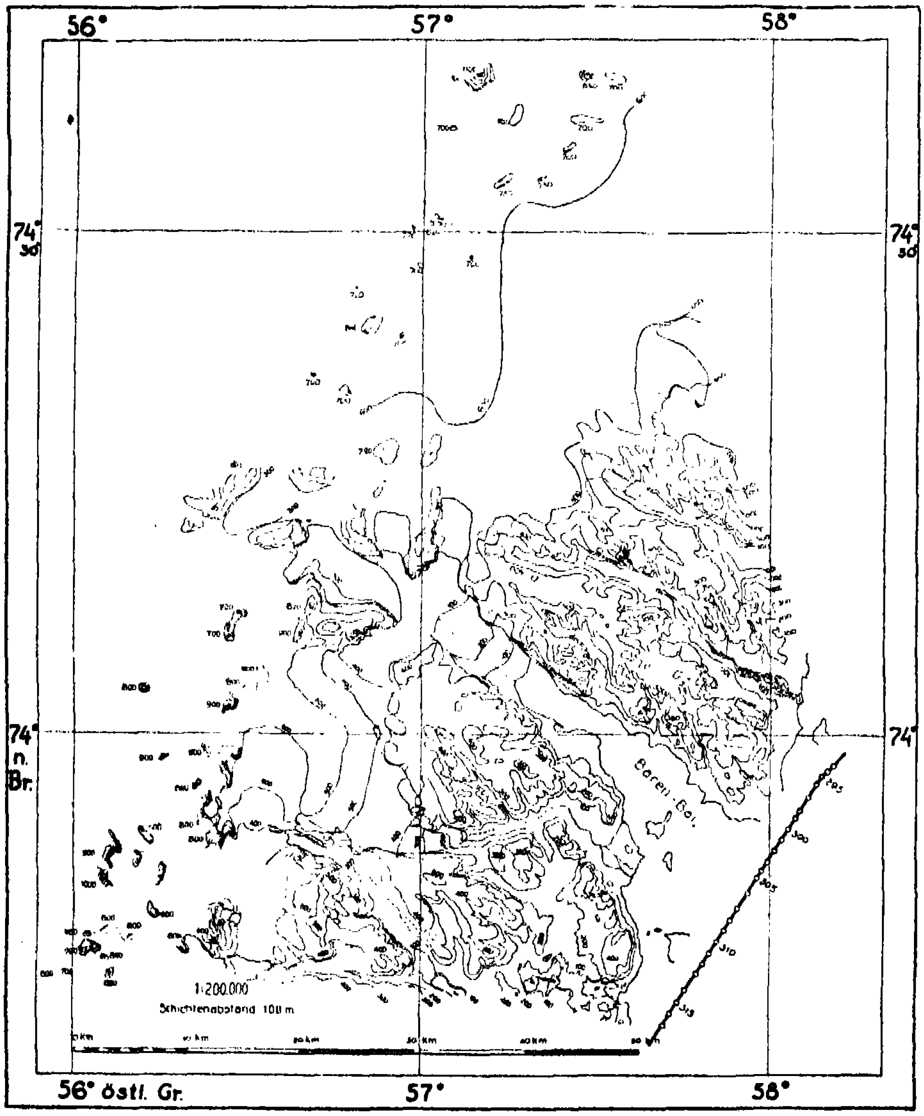

FIG. 2.—Map of part of south-east Novaya Zemlya made from the *Graf Zeppelin* survey.

The conclusion is reached that the old polar technique still maintains its superiority, for there is no doubt that when the results are worked out, those of the Ahlmann expedition will prove the richest; but the airship has definitely 'arrived' and one can confidently anticipate further developments of its usefulness in this field of exploration. Judgment cannot yet be passed upon the submarine—a better boat than the *Nautilus* must be available—but Prof. Sverdrup is of the opinion that "the U-boat will prove the ideal means of travel across the polar sea in summer, and that with the U-boat it will be possible to obtain full knowledge of the oceanography of the Arctic".

A description of the photographic apparatus carried by the *Graf Zeppelin* and an account of the methods employed in the preparation and orientation of maps based upon the photographs has been given by Otto V. Gruber,* from whose paper the accompanying illustrations are produced by courtesy of Messrs. Carl Zeiss, Ltd. The general procedure is similar to that which is adopted in aeroplane photogrammetric surveys. One of the addi-

* "Über die photogrammetrische Ausrüstung des *Graf Zeppelin* auf der Arktisfahrt 1931 und die Auswertungsmethoden für das gewonnene photogrammetrische Beobachtungsmaterial." *Bildmessung und Luftbildwesen*, No. 4, 1931. (Liebenwerda, Sachsen: R. Reiss G.m.b.H.)

tional advantages of operating from an airship is that under favourable conditions the shadow of the vessel appears on the photographs (Fig. 1), thus providing a control over the orientation and scale of the map.

As an example of what can be accomplished by airship survey, we reproduce the map (Fig. 2) of a part of south-eastern Novaya Zemlya showing the coastal region and the inland ice. The map is on the scale of 1/200,000 with contours at 100 m. intervals, and the errors in scale and height are stated not to exceed 10 per cent—probably not 5 per cent. The latitude and longitude may be as much as 1° out, and to correct this it would be necessary to determine by astronomical methods on the ground the true position of some point identifiable on the photographs, or to extend these to include some known point.

L. H.

Obituary

SIR DORABJI TATA

IN the memorial to his wife which he settled shortly before his death on June 4, Sir Dorabji Tata described himself as "The Last of his House". That is painfully true; with his passing an end comes to a family which played a great part in the intellectual and industrial renaissance of India.

Dorab Tata's rôle in this was that of the executor rather than the creator. The pioneering was done by his father, Jamsetji Tata. Having founded the family fortune firmly by establishing a prosperous cotton-spinning business, he bent his adventurous talents to three great enterprises—the establishment of an Institute of Science to prepare Indians for the direction of modern large-scale industries; the construction of iron and steel works as an essential link in the economic cycle; and the harnessing of the prolific rainfall of the Western Ghats to electric power stations to relieve the dependence of Bombay on far-distant coal-fields. But he died before any had reached the final stage; on the contrary, the freedom with which he spent on the development work rather seriously 'locked up' the family resources.

At this stage Dorab Tata took control of the business. With the active sympathy of his brother, the late Sir Ratan Tata, he set himself the filial task of completing his father's work. After many discouragements, thanks to the co-operation of Lord Curzon and the Government of India, the Institute of Science was established at Bangalore. Thence a steady stream of well-trained Indians has passed into the service of Indian industry. Unfortunately, Bangalore, though admirably suited climatically, is so far from the industrial centres that its activities do not command the interest and support which they should receive; but the work goes on.

The history of the Iron and Steel Works at Jamshedpur reads like a romance. The dogged tenacity with which Dorab Tata and his expert advisers searched the Central Provinces for ore surprised even his closest friends; for he was born to easy days. When their patience was rewarded by the discovery of a hill of iron ore of the finest quality at Gurumashini, the quest for capital was as baffling as that for "The Golden Girl". British enterprise does not come well out of the test. Though the existence of the requisite materials was established beyond doubt, and the home market justified the establishment of large-scale manufacture, British capital was timid and exacting, and no progress was possible. Fortunately, on the crest of the *swadeshi* wave India took this opportunity to itself and subscribed the money with an ease which surprised everyone; but equipment and operation were American and German when the British industrialist and financier missed their opportunity.

The same wave of constructive enthusiasm launched the hydro-electric works with Indian capital. Though the three associated companies—the Tata Hydro-Electric, the Andhra Valley, and the Tata Power—are capable of delivering electrical energy in Bombay far beyond the capacity for absorption, the heavy capital cost, especially during construction, has not given industry the cheap power which it demanded.

Here Dorab Tata himself would have been glad to call a halt. He was a rather reluctant partner in the manifold activities into which his house launched, and which brought anxious days when the post-War reaction set in. But he rose to the occasion and placed his private fortune behind the Iron and Steel Company when the dark days came, and, backed by the indomitable courage of his cousin, the late Mr. R. D. Tata, weathered the storm.

The qualities which Dorab Tata brought to this work were those of tenacity rather than of originating power, and a fine financial integrity. He was always willing to pay for brains, even extravagantly if he got the best. His monument is the Institute of Science, with its encouragement of pure industrial research, and the iron and steel industry, with linked enterprises, which has created a hive of industry in the virgin forests of Chota Nagpur. The contribution of his house to the renaissance of India is the recognition of the indispensability of science to modern industry, and the patriotic vision which looked beyond 'penny-in-the-slot' enterprise to the foundation of key industries, which though expensive are essential to the economic cycle.

STANLEY REED.

DR. B. A. BEHREND

DR. BERNARD ARTHUR BEHREND died on March 25 this year, in Wellesley Hills, Mass., at fifty-six years of age; and a correspondent who knew him intimately has sent us the following appreciation of his life and work, to supplement the many memoirs which have appeared in our engineering contemporaries.

Behrend was a man of the widest interests, and

made his mark and his influence felt wherever those interests drew him. As an electrical engineer his far-sighted and vigorous pioneer work made him known as in the first rank in Europe and America. His early recognition of the genius of C. E. L. Brown (Brown, Boveri and Co.), as indicated, for example, in his series of articles in 1901–2 on "The Debt of Electrical Engineering to C. E. L. Brown", illustrated his intuitive engineering faculty for seizing and advancing upon the best features of current practice, when not actually initiating them. He had been very appreciative of encouragement in his early career from such men as Gisbert Kapp and André Blondel, and this made him ever watchful to encourage and give such praise as might fairly be given to his young assistants; indeed, many of them were of his own age or older, since he had achieved much, and had established himself, while yet quite a young man.

Behrend's literary and philosophical leanings resulted in his home being built around his library, whether in Cincinnati, Milwaukee, Pittsburgh, or Boston; while a strong antiquarian bent for early colonial furniture turned him into a collector of note. He had a wide knowledge of general scientific writings, and perhaps no man held a higher place in his esteem than Thomas Henry Huxley; he made a pilgrimage to Mrs. Huxley at 'Hodeslea' in 1910. Charles Darwin, Andrew D. White, John Perry, were intimate book acquaintances. But it was not merely such men, their fame already established, whom he held in honour, for he often showed himself an alert and aggressive champion of interests which would otherwise have continued in undeserved neglect, as witness his well-known successful activities on behalf of Oliver Heaviside.

Behrend was the recipient of many honours, and a year before his death the honorary degree of doctor of engineering was conferred upon him by Darmstadt. As an American citizen he was loyal and patriotic, but believed that the time was past for intense nationalistic feeling in men of affairs. Of comparatively small stature and frail health but intense vitality, Behrend was an antagonist indeed to be reckoned with when his indignation was stirred, but was a man of large generosity, both in sentiment and practically, to a host of men who long will gratefully remember him.

As publicity has been given to the fact that Dr. Behrend took his own life, it should be recorded here that he was convinced that he was suffering from an incurable cancer. His last years were enriched by his marriage in 1926 to Margaret Plumer Chase, of whose devotion during the long illness preceding his death he wrote in eloquent terms.

WE regret to announce the following deaths:

Prof. Bernhard Bang, formerly veterinary adviser to the Government of Denmark and professor of internal diseases at the Royal Veterinary College, Copenhagen, known for his work on tuberculosis, on June 22, aged eighty-four years.

M. Albert Durand de Grossouvre, *correspondant* for the Section of Mineralogy of the Academy of Sciences, Paris, aged eighty-two years.

Prof. Aimé Sneider, formerly professor of zoology in the University of Poitiers, known for his work on the parasitic Protozoa, on March 27, aged eighty-seven years.

Prof. J. W. Young, professor of mathematics in Dartmouth College, Hanover, New Hampshire, author of numerous works on the fundamental concepts of algebra and geometry, on Feb. 17, aged fifty-two years.

News and Views

Early Man in Java

ON p. 20 of this issue of NATURE there appears a letter on the recently found Ngandong skull, from Prof. E. Dubois, whose discovery of *Pithecanthropus erectus* and close association with palæontological research in Java entitle him to speak with authority on the question of early man in south-east Asia. After careful study of Dr. Oppenoorth's paper, he has arrived at the conclusion that Ngandong man and Wadjak man are one identical type. This view carries with it certain implications, to which Prof. Dubois briefly refers, of no little importance in the study of the evolution of human types. Wadjak man is represented by two skulls discovered in the terraces of a dried-up freshwater lake near the southern coast of Java, one in 1889 and the second by Prof. Dubois himself in the following year, and brought back by him from Java in 1895, but not described until 1921. These skulls have been regarded as ancestral to the Australian; but it has been pointed out, notably by Sir Arthur Keith, that Wadjak man, so far as described, presents certain points of resemblance to Rhodesian man—for example, in the relatively enormous size of the palates, of which the area is identical. Prof. Dubois regards one of the Wadjak skulls, which in this respect differ *inter se*, as approaching the Ngandong skull in the shape of the occiput and other points; while Oppenoorth says of the latter that it resembles the Rhodesian skull, especially in the shape of the occipital bone, while the back of the skull "bears a resemblance to the Australian race". Thus with the Talgai skull of Queensland—probably pleistocene, and probably a relative of the Wadjak man, but still more closely related to the modern Australian—the newly discovered Javan skull apparently helps to link up a group of skulls, reaching out experimentally, if not in a direct line of ascent, to the modern Australian type.

Magic and Medicine Men

ALTHOUGH there is a great similarity in the supernormal performances of witches and medicine men wherever recorded, the selection of certain alleged powers of West African magicians as the subject of a challenge by the local Council of the Christian Missions (see NATURE, June 11, p. 862) adds interest to the

practices of certain members of the Bear gens of the Fox Indians of Oklahoma, to which reference is made in a recent publication of the Bureau of American Ethnology ("Notes on the Fox Wâpanowiweni": by Truman Michelson, *Bull.* 105). The bear, it may be mentioned, in parenthesis, is considered among the Fox to be the most dread form of witch. An Indian informant, who, significantly enough, wished to remain anonymous, stated that he himself had seen certain members of the gens remove stones or feathers from a box without touching it or its contents. Balls of fire were produced, and skins of snakes and cat and otter skins came alive and spoke. In the matter of the closed box the identity with the West African claim is noteworthy. Other performances resembled those of the spiritualistic medium. Stones ran round in a circle. The witches successfully called on the Wâpanowi birds (spirits) to come; they handled red-hot coals without suffering harm, and plunging their bare arms into boiling water, took out meat with impunity. This last feat has been recorded among a number of the American Indian peoples.

AN attempt by Fox Indian witches to injure or kill an individual who sought to ward off their attempts on his sister, was frustrated by giving them a feast at which the food provided by their host and intended victim was the head of a witch who had been captured by burning cedar leaves. When the witches invited him to a ceremonial feast, they were unable to take the meat from boiling water with bare arms, but he succeeded; they handled red-hot coals and he did the same. Then they became afraid. The next day the ceremony ended without any special event. Presumably the intended victims had evaded the danger. It will be remembered that it was claimed for the notorious medium Home that he had transferred his immunity to red-hot coal to someone else for a brief period; but with the Fox the transfer would seem to have been involuntary, although, it is said, the intended victim had been told previously "how to excel in shamanistic tricks". It has been questioned whether medicine men and shamans have the hypnotic powers sometimes claimed for them—rather, it is to be feared, as the last resource of an exhausted attempt at explanation; but it may be noted that it is said of one Fox witch that "when he was looked at steadily by anyone, the other became sleepy, . . . and . . . when [anyone] did not take his gaze from him, he fell asleep".

Anniversary of the Science Museum

THE South Kensington Museum was first opened to the public on July 1, 1857, and the seventy-fifth anniversary is being marked at the Science Museum by a special exhibition of technical apparatus, etc., which will remain on view until October. The wonderful progress which has been made in all branches of science and technology is shown by exhibiting examples which were in use during the decade 1850–60 alongside the corresponding types which are in use to-day, and emphasising the contrast in the descriptive notices. Air, land, and water transport are represented, and the remarkable advances which have been made in mathematical instruments, lighting equipment, telegraphy, typewriters, sewing machines, marine engines, pumping machinery, stationary engines, metallurgy, and other fields are shown by actual examples or by scale models. The discovery of the first artificial dye by W. H. Perkin in 1856 provides a very striking example of the progress made in industrial chemistry when the products of that date are compared with those of the dyeing industry of to-day. Besides a type exhibit placed among the others of the exhibition, a much larger and more representative display of modern dyes and dyed materials has been arranged in Gallery 66 on the top floor of the Museum. A series of plans shows how the Gore Estate has been developed by the Commissioners of the Great Exhibition of 1851 during the past eighty years, from the original group of green fields to the great intellectual centre which it is to-day. Since the South Kensington Museum, now represented by the Victoria and Albert Museum and the Science Museum, was established on the initiative of the Prince Consort, the attendance records total more than seventy-eight million, and about two million visits annually are still recorded.

National Prosperity and Control of Production

IN a pamphlet entitled "The Next Step", Capt. Harold Macmillan, M.P., advances the proposition that prosperity is conditioned by equilibrium in production. If the forces of production are properly distributed in the production of consumptive goods, and if the rate of saving is equalled by the rate of capital investment, then the total products will exchange against each other and prices and employment will be stable. This is the ideal production balance, but the difficulty of maintaining it becomes evident when it is visualised as a continuous rather than a static balance. Fluctuations are inevitable, and the balance may be upset by financial, political, or industrial forces. Capt. Macmillan therefore argues that it is necessary to create an organisational structure which will guide the flow of capital investment, secure the production of commodities in the quantities which scientific market study directs, and maintain stability of prices as the governing principle in credit policy. To attain these ends, he advocates the following programme: (1) a scientific system of selective protection of our home market; (2) the establishment of representative national councils for each industry, to co-ordinate purchasing, production, marketing, and research; (3) the creation of an investment and development board representing the Government, industry, and finance, to direct investment into the correct channels, to influence credit policy, and to direct the efforts of the councils of industry so as to achieve a new internal production balance in relation to the most scientific estimation of market requirements; (4) reflation to the 1928 price level.

CAPT. HAROLD MACMILLAN also advocates the "planning of stability". He argues that Britain has inherited a population and economic structure adjusted to a stage of world development which is past. Adjustments must now be made which ought to have

been taking place in response to these changes as they occurred, while in the future continuous adaptation will be required. Britain has now entered a period in which planning—conscious direction and intelligent anticipation—is essential to national welfare. Industry is already striving towards that integration and unity which modern conditions demand, and these efforts must be assisted. A sufficient measure of centralisation of control is required to enable the activities of separate industries to be brought into harmony with the economic objectives essential to national welfare and prosperity as a whole. The units of productive effort need to be controlled by a co-ordinating central authority sufficiently representative and sufficiently powerful to direct capital and labour into the correct channels to maintain equilibrium. Even already, Britain has been moving into this field of conscious endeavour by the road of protection, agricultural marketing, the regulation of wheat and coal production, the centralised direction of electrical power distribution, and now by the subordination of credit to the needs of industry. Mistakes have, of course, been made in the past, but improvements will have to be carried out as experience is gained.

New Index Number of Profits

IN his valedictory address on June 21 as president of the Royal Statistical Society, Sir Josiah Stamp described a new index number of profits, which he has constructed. This consists of a general index of profits designed to show changes in the return to capital as a whole and a special sub-index showing variations in the return for risk-bearing capital (ordinary shares, etc.). Both indices are comparable with the index of production, the various price indices, and other statistics. For technical reasons, the year 1924 has been selected as the base period, but the numbers have been carried back to 1920 as shown in the following table:

Year.	General Index.	Special Index.
1920	107·0	112·0
1921	68·7	57·3
1922	90·4	84·6
1923	94·1	90·6
1924	100·0	100·0
1925	104·1	109·3
1926	98·3	103·0
1927	106·5	111·4
1928	106·2	110·7
1929	109·9 *	114·3
1930	100·9 †	94·4
1931	92·0 †	80·9 *

* Provisional, subject to early verification.
† Very provisional.

Sir Josiah Stamp pointed out that his index referred to changes in the *aggregate amount* of profits, and not to the *rate of return* on capital. Inasmuch as a large increase has taken place in invested capital since 1924, the fall in the rate of return per unit of capital is greater than that of any fall indicated by the aggregate index. The index shows that the range of boom and depression is far smaller in Great Britain than in the United States.

The Patents and Designs Bill

CONFIDENCE which was placed in the Joint Chemical Patents Committee on its formation has been fully justified by the record of its activity. This committee of the Association of British Chemical Manufacturers, on which the Chemical Society, the Institute of Chemistry, and the Institution of Chemical Engineers are represented, gave evidence before the Board of Trade Departmental Committee on the Patents and Designs Acts and the practice of the Patent Office, during the inquiry which extended over eighteen months. The Patents and Designs Bill recently introduced into Parliament proposes to give effect to the recommendations of this Departmental Committee, generally known as the Sargant Committee; on publication, the Bill was examined by the Joint Chemical Patents Committee, and was considered still to contain a number of points of importance requiring amendment. As a result of the presentation of a memorandum to the Board of Trade, followed by a deputation, almost all the desired amendments have been secured at the committee stage of the Bill. For example, more effective provision for dealing with the abuse of user patents, whereby the manufacture of non-patented substances was being restricted or entirely prevented in Great Britain, has been obtained. The section dealing with the remedy in case of groundless threats of legal proceedings has been amended, and the appeal tribunal is to have power to obtain the technical assistance of an assessor in all cases. So far as the costs of appeal are concerned, the present atmosphere of appeals to the law officer is to be preserved, although in certain respects the tribunal will be regarded as a court of the High Court. It is a valid claim that these major amendments will both strengthen the new Act and afford great assistance to the poor inventor.

Prof. H. Brereton Baker

ON the occasion of his seventieth birthday, Prof. H. Brereton Baker and Mrs. Baker were, on June 25, entertained at dinner at the Imperial College of Science and Technology by a number of colleagues and former pupils. The rector of the Imperial College, Mr. H. T. Tizard, presided, and the company included distinguished representatives of those who had been associated with Prof. Baker's work at Dulwich College, at the University of Oxford, and at the Imperial College, London. *Ave* was, however, accompanied by *Vale*, for at the end of the present academic year Prof. Baker retires from the directorship of the Chemistry Department of the Imperial College and from his chair of chemistry in the University of London; fortunately, however, Prof. Baker will continue actively to prosecute his researches, and will occupy accommodation which has been placed at his disposal for that purpose by the College. Tribute was paid to Prof. Baker's work, both for chemical science and for the institutions with which he has been associated, by Mr. Tizard, Mr. R. T. Lattey, Mr. D. L. Chapman, and Prof. H. E. Armstrong. During the evening an inscribed album was presented to Prof. Baker, and Mrs. Baker was asked to accept a piece

of jewellery; decision regarding the nature of the principal gift awaits the intimation of Prof. Baker's wishes. It is known, however, that Prof. Baker, whose interest in the establishment of the College hostel has resulted in so marked a development in the students' social life, is anxious to commemorate his association with the Imperial College by placing a clock in the quadrangle, and intends to devote the major part of the presentation fund to that purpose.

New Buildings at Rothamsted

THE annual inspection of the experimental plots and laboratories at Rothamsted on June 21 was made the occasion of the official opening of a new block of buildings at the farm and the inauguration of an extensive electrical installation in the farm buildings. The Right Hon. Sir John Gilmour, Minister of Agriculture, declared the buildings open, in the presence of a large gathering of guests representing all branches of agriculture and the allied industries, and many of the visitors came from distant parts of the Empire. The new block of buildings will serve both the field experimental and demonstration sides of the farm. It contains an artificial manure store, working and office accommodation for the field experimental staff, and equipment to deal with the drying and preparation of the numerous samples taken in the course of the modern experiments. The purpose of the demonstration room is to facilitate the presentation of the field results which have direct practical interest in a way which is easily grasped by visitors. Diagrams and models take the place of tables of figures. Good types of machinery are illustrated, successful rations fed on the farm are on record, and exhibits of plant disease are set up as they become available. The electrical installation, designed by the General Electric Company, Ltd., will be of the most modern and complete kind, and will provide very valuable information as to the cost and general efficiency of motor-driven farm machinery in comparison with the older oil-driven type. The many visitors to Rothamsted are always interested in the excellent collection of modern implements loaned or presented by the makers. The installation of electrical equipment will greatly add to the demonstration value of this side of the farm.

Southern Railway Electrification

APPRECIABLE progress is being made on the Southern Railway's London-Brighton electrification scheme. According to the *Electrician* of June 24, 'stream-lined' electric trains have been undergoing night time tests. The first half of the new scheme—the extension to Three Bridges—will be opened on July 17. Thirty-three new trains will be employed, fitted with high speed motors and stream-lined, so that speeds of 70 miles an hour will be possible. The third class compartments have been built like the old first class compartments, and extra width has been given to the seats. The coaches have been built to the maximum width limit of the track, so it is impossible to use the 'bay window' type of look-out for the guard. The guards will see the signals through a periscope which projects through the roof. The signalling system has been changed throughout the route from the semaphore to the colour-light type. Whenever a train passes, the signals are automatically put to danger. An ingenious device is fitted in every signal-box which enables the signalman to know the exact nature of the trains that are approaching and their times. From July 17 there will be 61 trains running daily from London to Three Bridges, compared with 27 at present, while Three Bridges will have 57 trains to London in place of 19. The fastest trains have been timed to do the 30 miles in 39 minutes, but the average time for all the trains has been reduced from 60 to 52 minutes. The second stage of the scheme will probably be completed by March next.

Gyro-stabilisers for Liners

ALTHOUGH the theory of the gyroscope has been taught for more than fifty years in several universities, it is only recently that the instalment of gyro-stabilisers for ships, yachts, and aircraft carriers has begun to be adopted. The largest gyro-stabilising plant in the world has recently been completed for the new 46,000-ton luxury Italian liner *Conte-di-Savoia* at the works of Messrs. Vickers, Armstrong, Ltd., Barrow-in-Furness. An interesting account of the plant is given in the *Metropolitan-Vickers Gazette* for April. The plant consists of three identical stabiliser equipments, each one of which can function as a stabiliser independently of the other two. The rotating element in each consists of two solid forged steel disks. The rotating part (the rotor) weighs 110 tons and at normal working speeds it rotates at 910 revolutions per minute, being driven by a spinning electric motor mounted directly on the shaft. This motor is of the three-phase type and gives 560 horse-power at the normal speed. It is capable of giving 750 horse-power for 90 minutes during the accelerating period. The Sperry gyro-stabiliser is used, and this never allows the vessel to start rolling. A single wave can start a roll. In an unstabilised vessel, should the period of the rolling swings and the waves be the same, resonance might occur, and if the damping were small the rolling might become dangerous. Usually, however, the waves are only synchronous with the ship's natural swing for a brief period, and so its maximum swing is due to the accumulated effects of the waves. The Sperry device quenches the effects of these waves one by one, and so the stresses and strains on the hull of a stabilised ship are comparatively slight.

Human Improvability

DR. C. S. MYERS contributes an article on "Human Improvability" to a recent issue of the *Bristol Medico-Chirurgical Journal* (vol. 49, No. 183). He says that the problem of human improvability is as interesting as it is difficult. One difficulty lies in the definition of *improvement*, which is not necessarily synonymous with *progress*, and for which we can have only subjective criteria. The prevailing biological view is that all changes in living form and function are evoked by accident, and are perpetuated by heredity and by their suitability to the environment; improvement might then be regarded as involving a more perfect adaptation to the physical and social environment.

Some thinkers, however, find such a view inadequate to account for the facts, and therefore postulate in addition some, to us unknown, purpose in the universe. Our developing knowledge of other peoples has replaced many illusions as to natural differences by the recognition of likenesses as well, and confirms the importance of the social environment. It is not unlikely that man's mental and moral development depends in part upon the relation between his inheritance and the physical and social environment in which he grows up. Dr. Myers analyses several modern environmental conditions and concludes that changes have occurred which justify a belief in human improvability; these improvements do not, however, appear to come from the innate improvability of a race but from the improvement in the social heritage. The paper is provocative and stimulating, and in view of Dr. Myers's intimate knowledge of many aspects of modern civilisation, it is worthy of very serious consideration. It is all the more important at the present time, when so much pessimism is shown in the interpretation of the changes which our environment is experiencing.

British Poisonous and Edible Plants

EXCEPTING works on poisonous plants from the agricultural and medical points of view, there is very little printed information available to the lay reader. Fortunately, most British poisonous plants are rare; but the most dangerous are those with an attractive and luscious appearance. Perhaps that is why, despite their scarcity, such plants are the cause of illness and even death to unwary ramblers, campers, and school children every year. The pamphlet recently published as a reprint from *School Nature Study* therefore comes as a timely warning, not only to the country child and the town child in the country, for whom it is written, but also to adults who take an active part in country life. The pamphlet, "British Poisonous and Edible Plants", written by Miss Hilda F. Rendle, after a few introductory remarks, gives a list of edible plants found growing wild. These are divided into black fruits, scarlet fruits, seeds and nuts, flowers, leaves, roots, and fungi. The second part deals with the poisonous plants, giving not only the well-known plants such as laurel, bryony, deadly nightshade, etc., but also some of the less familiar types such as the spindle with its attractive pink fruit and orange seeds, potato 'apples', and acorns. A few of these are illustrated. It is a pity that the fungi were not given more space. Only the common mushroom (*Psalliota*) is described, with the concluding remark that "all other fungi should be avoided". In the present day of extended country activities, this pamphlet should be welcomed by all school teachers, boy scouts troops, country rambling organisations, etc. Copies at 2½*d.* each or two shillings per dozen can be obtained from Mr. E. G. Clarke, 7 Stanley Avenue, Wembley, Middlesex.

Acquisitions at the Natural History Museum

THE Department of Botany, British Museum, has received 320 plants collected by Mr. H. St. J. B. Philby, on his recent Arabian journey and presented by the King of Hejaz and Najd. The plants are of interest botanically as being from an area previously unexplored. It has to be remembered that, from an economic point of view, plants are of the greatest importance in deserts, and according to Mr. Philby the Arabs know them so well as camel food or otherwise that they are able to judge the date of the last rains from their presence or absence. The Arab name is attached to each plant. Acquisitions of the Department of Minerals include meteorites collected by Mr. Philby, a piece from the 15-ton mass of meteoric iron discovered in 1930 near Mbosi in Tanganyika Territory, a piece of a meteoric stone which fell recently near Kirkuk, Iraq, and a specimen of pitchblende from the recently discovered occurrence on the Great Bear Lake, North-West Territory, Canada. Dr. Robert Broom has presented to the Geological Department a small series of South African fossil reptiles, several of which are the types of genera and species recently established by the donor. They belong principally to Therocephalian and Dicynodont genera, and range from Permian to Trias in age. Through the generosity of Rear-Admiral H. Lynes, Mr. Jack Vincent has been collecting for the Museum in Portuguese East Africa, the birds of which are very little known; already two consignments have been received. A collection of more than a thousand birds from Yunnan obtained by the late Mr. G. Forrest, the well-known plant collector, has been presented by the Godman Exploration Fund, while Dr. P. A. Buxton has presented a collection of some 750 birds made by him during the War in Iraq and Persia.

Publications of the Institut Henri Poincaré

THE completed first volume of the *Annales de l'Institut Henri Poincaré* (Paris: Institut Henri Poincaré; Les Presses Universitaires de France) contains a highly interesting set of papers on theoretical physics and its mathematical borderland, of varying degrees of difficulty, several of which have been referred to in our columns on their appearance. The contributions verging on the purely mathematical include two on integral equations, by Kostitzin and Carleman, one by Brillouin, on a hyperbolic equation, and two, by Lévy and Polya, on the calculus of probabilities. Relativity is represented by Einstein and de Donder, and quantum theory by Darwin, Fermi, Born, and Dirac. The other papers are by Brillouin, on fusion, and by L. Bloch, on band spectra. It will be evident that the list of authors is one of unusual authority, a feature continued in the first numbers of the second volume by the inclusion of Sommerfeld and Cabrera. Their respective papers also give in short the aim of all, which appears to be to comment on current problems, or to collect and criticise otherwise scattered work. The papers are based on lectures delivered under the auspices of the Institut Henri Poincaré, and the only important change to be desired is that less time should be allowed to elapse between the delivery of the lecture and the time when it appears in print.

Population of England and Wales

THE "Text" (final) volume of the Registrar-General's Statistical Review, England and Wales, 1930, has been published (H.M. Stationery Office, 2*s.* 6*d.*

net). It contains the official commentary on the vital statistics contained in Parts i. and ii., Medical and Civil Tables, already issued. The population at the middle of the year was estimated at 39,806,000 persons, made up of 19,075,000 males and 20,731,000 females, the excess of females being most marked in the age groups between thirty and fifty-five years. The death-rate, 11·4 per 1000 population, is the lowest on record. The deaths ascribed to cancer (57,883) are the highest yet recorded, but when standardised are almost the same as, and no higher than, the preceding year. Attention is directed to the increasing mortality associated with motor-vehicles, and particularly with motor-cycles. During the six years 1925–30, motor-cycles were associated with the deaths of 2752 young men between the ages of fifteen and thirty-five years, which is 2·8 times the number killed in the preceding 14 years. The corresponding numbers of young women were 316 and 79, a fourfold increase.

Grant in Aid of African Research

A FURTHER grant in aid of research in Africa by the trustees of the Rockefeller Foundation is announced. The sum of £3000 per annum for a period of three years has been granted to the School of Oriental Studies in the University of London for the furtherance of research in African linguistics. This subject is already included in the curriculum of the school as part of the work of the Department of Phonetics and Linguistics, acting in co-operation with the International Institute of African Languages and Cultures. Now that the Oriental Institute has this additional fund at its disposal, it will be possible to extend its activities in this subject especially in the field of original research. It will be remembered that the Rockefeller Foundation is already assisting liberally African research in Great Britain by the grant of £5000 a year, to be increased in certain contingencies to £10,000, to the International Institute of African Linguistics and Cultures; and this grant is being used to meet the cost of a scheme of research which has been planned to cover a period of five years.

Announcements

SIR WILLIAM BRAGG, director of the Royal Institution, left England on June 25 for a lecture tour in South America under the auspices of the Ibero-American Institute of Great Britain, of which H.H. the Prince of Wales is president. On the previous day Sir William was received by His Highness, who expressed his interest in the tour. Sir William is due at Buenos Ayres on July 15 and leaves there on Aug. 1, when he goes on to Rio de Janeiro, arriving there on Aug. 6 and staying until Aug. 14. At both places he will be the guest of the British Ambassador and will deliver lectures on recent work on X-rays and crystal analysis. Sir William is expected back in England about Aug. 29.

As noted briefly in our issue of June 11, p. 860, the centenary of the birth of Sir William Crookes fell on June 17. In 1859 he founded the *Chemical News*, and the issue of that journal for June 17 is very appropriately dedicated to his memory. Lord Rutherford contributes a descriptive article on the artificial transmutation of elements, Sir Harry McGowan has a short article on Crookes's well-known forecast of a world wheat shortage in relation to chemical industry, and other articles deal with various aspects of Crookes's life and scientific work. The issue includes full-page reproductions of photographs of Crookes and Lord Rutherford.

THE Medical Research Council announces that, on behalf of the Rockefeller Foundation, it has made the following awards of travelling fellowships for the academic year 1932–33; these fellowships are awarded to graduates who have had some training in research work either in the primary sciences of medicine or in clinical medicine or surgery, and who are likely to profit by a period of work at a chosen centre in America or, in special cases, in Europe, before taking up positions for higher teaching or research in the British Isles:—Mr. C. P. Beattie, Bacteriology Department, University of Edinburgh; Mr. W. D. W. Brooks, St. Mary's Hospital, London; Dr. Eleanor M. Creak, Maudsley Hospital, London; Mr. I. G. W. Hill, Royal Infirmary, Edinburgh; Mr. W. A. Mackey, Department of Surgery, University of Glasgow; Mr. D. J. Macmyn, King's College Hospital, London; Dr. J. C. Moir, University College Hospital, London. In view of the high qualifications of so many of the candidates, the Council greatly regrets that it has not been possible to make a larger number of awards.

MESSRS. H. K. Lewis and Co., Ltd., 136 Gower Street, W.C.1, have just issued a very useful classified catalogue of books, in new condition, on physics and mathematics. An admirable feature is the insertion of the year of publication of each volume.

UPWARDS of 2000 works dealing with ornithology are offered for sale, at what appear to be reasonable prices, by Messrs. Wheldon and Wesley, Ltd., 2 Arthur Street, W.C.2, in catalogue New Series, No. 28. The catalogue is obtainable free upon application.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A full-time lecturer in the Department of Building of the Leeds Technical College—The Director of Education, Education Department, Calverley Street, Leeds (July 6). A teacher of metalwork and technical drawing, and an assistant master to teach principally chemistry and mathematics, in the Junior Technical School of the Castleford, Normanton, and District Mining and Technical Institute, Whitwood—M. G. Swaine, Education Offices, Castleford (July 8). An assistant lecturer in mathematics in the University of Birmingham—The Secretary, The University, Birmingham (July 15). A lecturer in pharmacology in the Department of Physiology of the University of Bristol—The Secretary and Registrar, The University, Bristol (July 22). A secretary of the Jamaica Agricultural Society—The Secretary, Jamaica Agricultural Society, 11 North Parade, Kingston, Jamaica, B.W.I. (Sept. 5).

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Early Man in Java

THE paragraph on early man in Java, in NATURE of June 11 (p. 863), concerning the Ngandong skull, induces me to make the following remarks.

Mr. W. F. F. Oppenoorth, who described the skull, says in the Summary, p. 63 of his paper :[1]

"Just in those features, where the Ngandong skull deviates from the Neanderthal type—especially in the shape of the occipital bone—it approaches a skull, found some ten years ago in South Africa, now known in literature as the Rhodesian skull ; the torus supraorbitalis, however, of the Ngandong skull is not so heavy and a little more bent.

"The back of the Ngandong skull also bears resemblance to that of the Australian race, so perhaps we may see in it a much more primitive prototype of that race than was the Wadjak man of Dubois.

"I think it justifiable to separate the Ngandong skull and call it *Homo (Javanthropus) soloensis*, n. subg., n. sp."

I may here direct attention to the well-known fact that in the slope of the nuchal plane of the occipital bone, there is a wide range of variation in Australian skulls, and there is also great individual difference, in this respect (among other things), between the two skulls of Wadjak man,[2] from one of which only I described the strikingly primitive upper and lower jaw, the brain case and the other bones of the face being in a fragmentary and incomplete condition. This skull much more approaches the Ngandong skull, in the shape of the occiput and in other respects.

A careful study of Oppenoorth's paper, which is called a 'preliminary' report, leaves little doubt, however, in my mind, that Ngandong man and Wadjak man are one identical type. The new skull, in my opinion, bears out the proto-Australian character of the Wadjak type, and also tends, I believe, to designate Rhodesian man as the prototype of the species *Homo sapiens*.

EUG. DUBOIS.

[2] Described in *Proc. Kon. Akad. Wetenschappen*, Amsterdam, vol. 23, pp. 1013-1051, two plates ; 1921.

The Inheritance of Acquired Characters

PROF. MACBRIDE'S criticism[1] of my lecture on the inheritance of acquired characters falls into three parts. He claims that I have misinterpreted Lamarck, that certain experiments demonstrate the transmission to the offspring of characters acquired as the result of a change of environment, and finally that this latter principle can be inferred from other facts, apart from the results of any experiment.

Lamarck, as I pointed out, used different language on different occasions. I think that my second citation from him shows that, sometimes at least, he expressed the views which I attributed to him.

I am glad that Prof. MacBride does not deny that Dürken employed selection. But, he writes, "selection as an effective cause of anything is a superstition that dies hard". Selection is quite an effective cause of change of the proportions in which various types occur in a mixed population. And such a change was all that Dürken obtained. Some of his original population gave green pupæ. He selected these, and got a larger proportion in later generations. The facts cited by Prof. MacBride in his letter as to the behaviour of certain larvæ in orange light are irrelevant to the issue, namely, whether this treatment, apart from selection, increases the proportion of green pupæ *in a given environment*, in successive generations.

I must apologise, in this connexion, for writing *Pieris rapæ* for *P. napi*. I must also apologise to readers of NATURE for quoting Prof. MacBride's account of Metalnikoff's experiment rather than the original. I have read three accounts by Metalnikoff of his experiments, and from none of them can I discover whether he bred from those caterpillars which had been immunised both with living and dead bacteria, as appeared from Prof. MacBride's lecture, or only from the latter class, as he states in his letter. The interpretation of his results depends on which alternative was true.

Prof. MacBride dismisses a hypothesis which he attributes to me as "fantastic", on the ground that *Salix rubra* is a rare hybrid. Actually it is of such economic importance that three different strains of it are grown for basket-making, and common enough to occur in sixty-nine of Druce's British vice-counties. On the other hand, the original host species *S. andersoniana* is an economically unimportant plant occurring in only thirty-four vice-counties. The hypothesis that some of the ancestors of flies colonising the latter had lived on the former does not appear particularly fantastic. Of the "larval memory hypothesis" we read that "it assumes that the instinct of the mother to seek a certain plant and the capacity of the larva to live on this plant are inseparable". After discussing the larval memory hypothesis I actually wrote, "The *other* factor in successful colonisation is the ability of the larva to eat and digest its food". The assumption (which is clearly false) was therefore Prof. MacBride's and not mine.

Against the eminent authorities cited in favour of Lamarckism, I will only quote one, namely, the Royal Society's motto, "Nullius in verba". I am awaiting such experimental confirmation of their views as would be furnished by a successful repetition of McDougall's experiment.

To call the alternative theory that of "Chaos and Chance" does not, of course, disprove it. The kinetic theory of gases proves that chaos and chance can form the basis of very exact and fully verifiable predictions. Unfortunately for the kinetic theory of species, conditions in a natural population are not chaotic. Mutation does not occur in all directions. From a knowledge of the types of mutation common in one species we can predict those common in another. And mating is not in general at random. If a species were a real chaos, the theory of evolution would be nearly as simple as the kinetic theory. So I fear that Prof. MacBride's phrase may have led readers who are acquainted with that theory to suppose that the case for neo-Darwinism is even stronger than is actually the case.

Developments in the Chemistry of the Anthocyanins

IT is a remarkable fact that almost the whole range of anthocyanin pigments of flowers, fruits, and blossoms is derived from the three fundamental anthocyanidins, namely, pelargonidin, cyanidin, and delphinidin, by various substitutions in the hydroxyl group. A very extensive survey of the colouring matters of this class conducted during the last two seasons has only served to emphasise the prevalence of the three known types.

Nevertheless, the existence of exceptions has already been recognised by Willstätter, who found that the bluest anthocyanins occurring in the beet, in *Celosia cristata*, and in *Atriplex hortensis* are nitrogenous pigments. At the other end of the scale, the most yellow anthocyanin was noted in *Papaver alpinum*, and a similar substance which colours the yellow Iceland poppy is in progress of investigation in this Laboratory by Miss R. Scott-Moncrieff. Quite a different anthocyanin has now been found to occur in the orange-red flowers of *Gesnera fulgens* (or *G. cardinalis*). This anthocyanin we propose to term *gesnerin*, and it is a 5-saccharide (unidentified sugar residue) of 4′ : 5 : 7-trihydroxyflavylium chloride. On hydrolysis it yields the anthocyanidin chloride which was readily identified as apigeninidin chloride,[1] the synthesis of which was effected in 1925 because it was thought probable that a derivative of the substance would occur in Nature. The major anthocyanidins are related to naturally occurring flavonols and it was thought probable that similar substances derived from the flavones in a similar way might be encountered ; this expectation has now been realised in the case of the anthocyanidin related to the flavone apigenin. A further search among the Gesneriaceæ and other families of the Personales will be made, since it seems very probable that the anthocyanin derived from luteolinidin will also be encountered.

The suggestion first made in these columns, that some of the more important anthocyanins are 3 : 5-diglucosides, has been amply confirmed by synthesis. Dr. A. R. Todd in collaboration with one of us has already succeeded in synthesising hirsutin, malvin, and cyanin chlorides, and synthetical indications have been obtained in regard to peonin and pelargonin chlorides ; all these pigments bear two glucose residues separately attached to oxygen atoms in positions 3 and 5 of the anthocyanidin molecule. An independent confirmation of the correctness of these views is obtained from the work of Prof. Karrer and his colleagues, who have been able to show that the process of oxidation of many anthocyanins by hydrogen peroxide, followed by hydrolysis, results in the detachment of only one hexose unit, obviously that attached to position 3 (private communication). The hypothesis that anthocyanins of the mecocyanin type are 3-biosides has also been confirmed by synthesis of representatives of all the possibilities (for example, cyanidin 3 : 7-diglucoside, 3-cellobioside, and 5 : 7-diglucoside), and by an examination and comparison of their properties.

We were naturally much interested in the letter of Mr. W. J. C. Lawrence[2] on the subject of the co-pigments which modify the colour of dahlias, pelargoniums, etc., as we have long been of the opinion that the chief co-pigments are the tannins and anthoxanthins, including the flavone and flavonol glucosides. Until, however, these substances have been isolated and identified, speculation as to their nature seems premature. Nevertheless, experiments with pure anthocyanins and pure flavonol derivatives have proved very suggestive, and, for example, the appearance and properties of a co-pigmented violanin solution from purple violas can be simulated by means of a synthetic anthocyanin in association with quercitrin.

We have found the phenomenon of co-pigmentation almost universal in flower colours, almost all of which are bluer than they should be at the *p*H obtaining in the cell sap. The degree of the effect is, however, very varied in different flowers, and, as we have already suggested, a genetic factor for flower colour is frequently connected with the development (or, it may be, the suppression) of a co-pigment.[3]

In addition, we pointed out that the co-pigment might remain as a constant factor in certain cases, and that a change of colour tone might result from an increase in the concentration of the anthocyanin. Thus in the ordinary lilac there is a co-pigment, found also in the white flowers, which with a low concentration of anthocyanin produces the familiar pale mauve colour ; the deeper red shades are the result of an increased proportion of colouring matter, and the deep bluer red varieties contain both pigment and co-pigment in greater concentration. An alternative to the latter part of this statement is obviously that a new and more efficient co-pigment has been developed.

Mass-Spectra of Helium and Oxygen

IN the course of my analyses of leads of different origins I have had opportunity of making some interesting observations on these two elements. While preparing a new discharge tube by preliminary running, a mixture of helium and oxygen was used and a search was made for the line due to He^{++}. The occurrence of doubly charged helium atoms *in the discharge* was inferred during the early work of Sir J. J. Thomson[1] and has recently been very beautifully demonstrated by Conrad,[2] but the evidence in each of those cases was indirect, namely, the prolongation of the normal helium parabola. All attempts so far made to photograph the line of He^{++} as a satellite of the line H_2 by means of the mass-spectrograph have been unsuccessful.

These failures I have ascribed to my use in the past of cooled charcoal (incapable of absorbing helium) for the high vacuum parts of the apparatus. This explanation appears to be correct, for by reducing the pressure in the slit system and the camera to a much lower value by a diffusion pump and lowering the intensity of the H_2 line by continuous washing with oxygen and helium, the doubly charged line of the latter has now been found. It is indeed still much too faint compared with H_2 for accurate measurement, but there is now reasonable hope that with a setting of the discharge tube more favourable to atomic lines and more careful washing it will be possible to reduce the pair to approximately equal intensity. The distance between these lines will then afford a really direct and trustworthy measure of the ratio of the masses of the helium and hydrogen nuclei, a figure of fundamental importance in nuclear physics.

During these experiments it was noted that the helium-oxygen mixture gave much stronger oxygen lines than did pure oxygen, and since the oxygen molecular line was so bright that it could be seen on the willemite screen, conditions were very favourable for the detection of the two faint isotopes of oxygen. The atomic lines 17 and 18 are unsuitable for this, owing to the presence of OH and OH_2, but the molecular lines 33 and 34 due to $O^{16}O^{17}$ and $O^{16}O^{18}$ respectively may be expected to be fairly free from

contamination. Furthermore, their intensities relative to the main line 32 will be double those of atomic abundance. On photographing the spectra all three lines were quite clear, and by giving suitable exposures, for example, 3 seconds and 15 minutes, their relative intensities could be estimated. Line 32 was found to be 268 times as intense as line 34, which was 4·2 times as intense as line 33.

These can only be regarded as rough minima, for owing to the action of the oxygen discharge on the wax and grease it is certain that sulphur is present, and if to the extent of 1 per cent, would enhance line 34 by about ten per cent and line 33 even more. It is clearly useless to push the accuracy further until an apparatus is available from which sulphur and other possible sources of contamination can be excluded, but so far as they are valid, the ratios 536 and 4·2 support the figures 630 and 5 given by Mecke and Childs [3] as against the lower abundances previously estimated.

An Ocean Sunfish in Malaysian Waters

THE species under consideration (*Mola lanceolata*) is so rare that I venture to think that a preliminary note on a recent capture may not be out of place in the columns of NATURE. A more detailed account will, it is hoped, appear in the *Bulletin of the Raffles Museum* during the course of the year.

A specimen of an ocean sunfish, *Mola lanceolata* (Liénard), was taken in a fishing-stake at Noembing, off Bintan Island in the Rhio Archipelago, during the night of April 11–12, 1932. Fortunately, the owner of the stake realised the unusual nature of his catch and presented it to this Museum.

The adult specimens now known appear to be as follows:

1. The type, described by Liénard in 1840, taken off Mauritius.

2. A specimen taken off Amboina and described by Bleeker in 1873 as *Orthagoriscus oxyuropterus* (*Vers. Akad. Amsterdam* (7), **2**; 1873). The "Zoological Record" for that year contains a reference to the possible identity of this species with *O. lanceolatus*, and Fowler (*B. P. Bishop Museum Occasional Papers*, **8**, No. 7, 1923, 387) includes it in the synonymy of *Masturus lanceolatus*.

3. A large specimen (2 metres in length) taken near the Azores by the Prince of Monaco (Johs. Schmidt, NATURE, **107**, 76; 1921).

4. A specimen in the Honolulu Museum recorded as *Masturus lanceolatus* by Jordan and Jordan (*Mem. Carnegie Mus.*, **10**, No. 1, 89; 1922, fig.). The authors refer to it as the third recorded specimen, but had evidently not seen Schmidt's work. A fuller account is given by Fowler ("Fishes of Oceania", *Mem. B. P. Bishop Mus.*, **10**, 474; 1928, fig.).

5. The present specimen. Like that from Honolulu, it is about 4 ft. in length.* The spotting of the caudal is much as in Fowler's figure, but only extends slightly on to the bases of the other vertical fins. The small gill opening is in the form of a short funnel, projecting backward, and there can be little doubt that it is used as an auxiliary steering apparatus by squirting out a jet of water, as suggested by Capt. Damant for *Mola mola* (NATURE, **116**, 543; 1925).

* According to Jordan and Jordan, the Honolulu cast is 4 ft. in length; presumably, therefore, this represents the length in life, but Fowler gives the length of the spirit specimen as 948 mm., or just over 3 ft.

The cartilaginous layer under the skin has a thickness in parts of about 1½ inches. The flesh was strikingly white, tender, and watery, disintegrating rapidly when scraped. In the stomach was a sucker-fish (*Echeneis remora* Linn.), 8 inches in length.

The remarks of Schmidt (loc. cit. and NATURE, **117**, 80; 1926) on the early stages of *Mola lanceolata* and allied species are of very great interest in view of the wide range from which the few known adults of *M. lanceolata* have been taken. If any specific or racial distinction could be found between these specimens, it would be logical to look for local breeding grounds. In the case of a single species, it would appear from Schmidt's conclusions that the Sargasso Sea is the nursery, and the wide distribution must be attributed solely to the action of ocean currents.

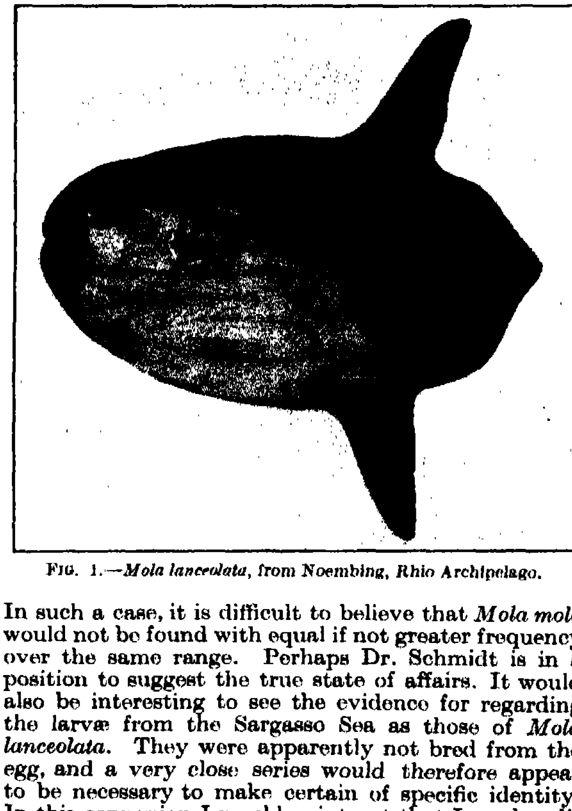

FIG. 1.—*Mola lanceolata*, from Noembing, Rhio Archipelago.

In such a case, it is difficult to believe that *Mola mola* would not be found with equal if not greater frequency over the same range. Perhaps Dr. Schmidt is in a position to suggest the true state of affairs. It would also be interesting to see the evidence for regarding the larvæ from the Sargasso Sea as those of *Mola lanceolata*. They were apparently not bred from the egg, and a very close series would therefore appear to be necessary to make certain of specific identity. In this connexion I would point out that I am handicapped by lack of literature, and have not been able to read Dr. Schmidt's detailed work ("Meddelelser fra Kommissionen for Havundersø-gelser", Serie Fiskeri, **6**, 1921), in which this latter point may be successfully met.

It seems probable that other specimens of *Mola lanceolata* have been taken and not put on record; duly authenticated notices of the capture of this species may help towards the solution of a problem of no little interest.

NORMAN SMEDLEY.

'Powder-Post' Beetles

As a result of detailed observations supplemented by experiments, it can be stated that the actual food of the larvæ of *Lyctus* spp. (the powder-post beetles) is the *starch* present in the cells of the wood they infest. This starch is the main reserve substance of the plant, is present in the sap-wood only, and varies in quantity

from species to species of tree; these facts explain why it is that *Lyctus* attacks only certain kinds of timber and then only the sap-wood. The starch also varies in the growing tree from month to month, and is present in greatest abundance in winter, that is, in the felling season for 'hardwoods'.

It is found that if felled timber is kept 'in the log' sufficiently long (about a year), the starch disappears entirely from the sap-wood, and such timber is proved to be immune to *Lyctus* infestation. If, however, timber is converted soon after felling and then quickly dried, as in kiln-drying or steaming, etc., the starch remains in the sap-wood and such timber is liable to damage; no subsequent (seasoning) treatment can remove the liability.

By seasoning susceptible species of timber 'in the log' the pest can be controlled in a simple and inexpensive way, and its eradication from timber yards and wood-using factories is thus a practicable proposition. Damage costing many thousands of pounds a year can be saved and sap-wood made valuable, instead of being (as in oak) valueless for most purposes.

Lunar Periodicity in Reproduction

A NUMBER of living organisms, particularly marine animals, exhibit a lunar periodicity in reproduction.[1] Tides do not seem to be a causal factor in this phenomenon, and it has been difficult to understand how moonlight could be responsible, since the intensity of the light of the full moon is only about 1/500,000th that of sunlight.

Various authors in the past have pointed out that the light of the moon is partially polarised, and have suggested that polarised light is the responsible factor in lunar periodicity. This suggestion has been repeated in recent letters in NATURE.[2, 3] There are no known instances, however, of polarised light affecting organisms, and the little experimental work which has been done to test this has given negative results.[4, 5] Moreover, animals and plants receive very much more polarised light from the sky during each day than they receive from the moon. The following approximate calculation makes this clear.

The area of the hemisphere of sky and the area of the full moon are respectively 20,627 and 0·196 square degrees. The intensity per unit area of the light of the full moon may be taken as being about five times the intensity per unit area of the light reflected from the day sky. Therefore,

$$\frac{\text{Total flux from sky}}{\text{Total flux from full moon}} = \frac{20{,}627}{5 \times 0{\cdot}196} = 2{\cdot}1 \times 10^4.$$

The maximum polarisation of moonlight occurs at the first and third quarters,[6] so that the maximum total amount of polarised light from the moon is received shortly after the first and before the third quarter. The light intensity of the full moon is about nine times that of half moon, so that

$$\frac{\text{Total flux from sky}}{\text{Total flux from half moon}} = 9 \times 2{\cdot}1 \times 10^4 = 1{\cdot}9 \times 10^5.$$

The maximum percentage polarisation of moonlight[6] is 9. The maximum percentage polarisation of light from the day sky is 85, and applies to the light coming from the sky 90° from the setting sun.[7] Taking a value so low as one per cent for the polarisation of light from the sky during the day, we get:

$$\frac{\text{Total polarised flux from sky}}{\text{Total polarised flux from half moon}} = \frac{1{\cdot}9}{9} \times 10^5 = 2{\cdot}1 \times 10^4.$$

It is evident, therefore, that very much more polarised light is incident on the earth during the daytime than on moonlight nights.

Moreover, even if the polarised light of the moon could cause a reproductive rhythm, this would be a bilunar, not a lunar, cycle, for the maximum polarisation is at the first and third quarters.

Recent experimental work,[8, 9] however, on the influence of light on sexual periodicity in general, suggests a way in which moonlight might impose a lunar periodicity. In mammals and birds the length of the breeding season appears to depend in part on the daily number of hours during which the animals are exposed to light. Thus the moon may perhaps cause a lunar cycle in reproduction, not through its relatively small intensity of light as compared with that of the sun, but by the additional total number of hours of illumination per 24 hours at full moon, over and above a threshold light value. Only experimental work can test this hypothesis.

A Genus of Ranunculaceæ hitherto Unrecorded for New Zealand

DR. W. A. SLEDGE, of the University of Leeds, who has recently brought home from New Zealand a collection of dried plants, kindly allowed me to look through his surplus stock of species belonging to *Ranunculus* and to take what flowers I liked for examination, as I am especially interested in the petal of this genus. One species, *Ranunculus tenuicaulis* Cheesem., appealed to me particularly on his information that he had noticed it when growing to have reddish flowers. Red colouring is unusual among buttercups.

On soaking out the two flowers available, I found on investigation that there was no sign of a double perianth. Thinking possibly that the sepals might have fallen, as these flowers were fully mature, Dr. Sledge supplied me with younger ones from his mounted sheet. These likewise showed a simple (monoseriate) perianth. Further, there was no indication of any nectary on the perianth segment or tepal, to use a non-committal term. The petal of *Ranunculus* is invariably characterised by the possession of such. The perianth, then, of this interesting plant is probably a petaloid calyx of five sepals. The small flower is borne singly on a short stalk arising from a whorl of three somewhat foliaceous bracts suggestive of the involucre of *Anemone*. The carpel is of a type quite unusual for *Ranunculus*, having a long spirally recurved style. The material at my disposal has scarcely been sufficient to ascertain definitely as to the exact manner in which the ovule is borne, but such evidence as has been obtained points strongly to a suspended rather than a basally attached one. Dr. Sledge has since satisfied himself that the ovule is suspended.

The examination of these flowers, then, certainly rules out *Ranunculus* as the genus to which this plant belongs, and suggests that the *Ranunculus tenuicaulis* of Cheeseman may be a species of *Anemone*. At any rate, it is a member of a Ranunculaceous genus hitherto unrecorded for New Zealand. So far, the only genera of this attractive family occurring in these islands are *Ranunculus* itself, by far the largest

with some 40 species, *Clematis* (9 spp.), *Myosurus* (one sp.), and *Caltha* (2 spp.).

The question naturally arises: How came the late Mr. T. F. Cheeseman to place this plant in the genus *Ranunculus*? Dr. Sledge in the letter below sheds some light on this. He hopes to secure more material of this interesting plant, and when it is available, we may then be able to determine exactly its systematic position. JOHN PARKIN.

Blaithwaite,
Wigton, Cumberland,
May 25.

I MAY perhaps supplement Mr. Parkin's interesting observations on *Ranunculus tenuicaulis* Cheesem. This montane species is rare throughout New Zealand and of most frequent occurrence in Otago, in which province I collected it. Single stations are also given in Cheeseman's "Manual of the New Zealand Flora" (Ed. 2, p. 442) for Canterbury and Nelson, whilst in the North Island the plant has been collected in the Tararua Mts. The plant was first collected by Cheeseman in 1883 at Arthur's Pass in the Southern Alps of Canterbury, and there are single authentic specimens of this gathering in the herbaria at Kew and the British Museum. We are indebted to the authorities at Kew and the British Museum for descriptions of these plants, both of which are in ripe fruit and lack perianth members, as does a second specimen at Kew collected by Kirk in the same locality a year later. In his original description of the species (*Trans. N.Z. Inst.*, vol. 17, 1884) Cheeseman writes, "Petals not seen"; and the inadequate references to the flowers in later descriptions in the "Manual", and particularly the absence of any reference to the very unusual and pronounced reddish colour of the perianth, would suggest that he never saw the plant in flower. His description of the achenes is more complete, and in the second edition of the "Manual" he adds the following note: "A very curious species, remarkable for the fusiform achenes and long spirally recurved styles". These "remarkable" facts are significant in view of Mr. Parkin's observations and the probable affinity of this plant with the genus *Anemone*. W. A. SLEDGE.

Reconstruction of an Indian Fossil Cycad

IN 1900, Prof. Seward showed, in a specimen found at Amrapara in the Rajmahal Hills, pinnate leaves resembling *Ptilophyllum cutchense* McCl. sp. organically attached to a cycadean stem of the *Bucklandia* type.[1] A *Williamsonia* flower discovered near the same locality a few years ago by Mr. G. V. Hobson of the Indian Geological Survey, and kindly placed at my disposal for description, proves to have belonged to the same plant as the *Bucklandia*. The stele of the peduncle shows that the wood is compact, as in the *Bucklandia*, and the structure of the bracts is identical in every way with that of the rhomboid leaf-bases preserved round the stem, which I have compared at the British Museum with kind permission of the authorities. There is also complete identity in structure with certain fragments of a *Williamsonia* flower, associated with another *Bucklandia* stem from Amrapara, described by Dr. N. Bancroft.[2] The flower is unisexual and ovulate; in structure it closely resembles *W. scotica* Sew., from the Jurassic of Sutherland.[3]

In a restoration which I have attempted, the plant has the habit of a miniature *Cycas*, with the surface of the stem covered by alternating zones of large and small rhomboid scars. The flowering shoots are shown projecting laterally from the columnar trunk, attached by an attenuated base and turned upwards, like the vegetative buds of the living genus. The name *W. Sewardiana* has now been proposed for the plant in supersession of the name *W. Sewardi* previously chosen,[4] as the latter name is preoccupied.

In view of our knowledge of the anatomy of the leaves, stem, and flower, this is now the best known species of *Williamsonia*. B. SAHNI.

The *p*H Stability Region of Proteins and Osmotic Swelling

THE swelling of protein gels and tissues under the influence of acid or alkali is due mainly to osmotic forces set up on account of salt formation between the protein and the acid or base. Osmotic swelling always shows two well-marked maxima, one in the acid and one in the alkaline range, and it has generally been taken for granted that the *p*H-swelling curve should also show a sharply marked minimum corresponding to the iso-electric point of the protein. This misconception has arisen from the fact that the bulk of the work on the swelling and osmotic pressure of proteins has been done on gelatin and albumin, both of which

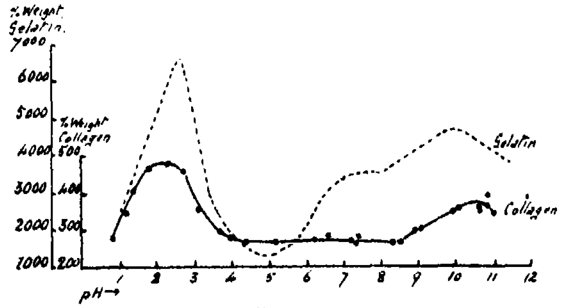

FIG. 1.

show sharply marked minima, and where it is not unreasonable to assume that the protein molecules are present without any orientation.

A very different state of affairs manifests itself, however, in protein structures, where there is evidence that the protein molecules are oriented on a definite system, generally lying parallel to each other, with the possibility of cross linkages. Examples of the effect of hydrogen ion concentration on swelling of proteins of this type show the appearance of a range of *p*H stability which becomes more emphatic with the development of a definite fibrous structure; muscle proteins, for example, have a stability range (roughly measured) of *p*H 5–7 or possibly 8.[1] The *p*H-swelling curve for collagen fibres is shown in the accompanying diagram (Fig. 1), together with the smoothed curve for gelatin. The contrast is striking, the curve for gelatin showing a sharp minimum at *p*H5 and that for collagen fibres a stability range of *p*H 4–8·5.

Keratin fibres (horse-hair) and silk fibres do not show osmotic swelling at any *p*H value, but begin to show swelling due to the breakdown of the structure by alkali at about *p*H 11–13. Speakman[2] has, however, shown that keratin fibres (wool) have a stability region against stretching forces of *p*H 4–8, and has

compared the stability range of wool keratin to the stability of protein aggregates described by Svedberg.[3] For serum albumin, the stability found by the ultracentrifuge extends from pH 4 to 9; for serum globulin from 4 to 8—this range is remarkably like the range of osmotic stability found in protein tissue.

Since osmotic swelling may, with considerable justification, be attributed to the formation of a colloidal ion by the protein, due to the formation of charge centres at the free amino or carboxyl groups, it appears that most native proteins have a tendency to form oriented aggregations so arranged that the attraction between the opposite charge centres is at a maximum. In other words, the molecules form cross linkages which are not readily opened up by slight changes in hydrogen ion concentration, and a stability region of pH becomes apparent. This molecular structure is not, however, stable towards all forces causing hydration of the protein. Collagen fibres resemble gelatin in showing marked swelling in salt solutions over the region between the iso-electric point and absolute neutrality. Keratin and silk fibroin do not show this salt action, possibly because the side spacings between the long protein molecules are so small that even the small molecules of electrolytes find difficulty in penetrating.

The Velocity of Light

IN NATURE for April 4, 1931, M. E. J. Gheury de Bray points out that the determinations of the velocity of light made in this century seem to tend towards smaller and smaller values the more recent the time of observation.

In this connexion the following remarks on the measurement of the standard metre in terms of the wave-length of the red cadmium line may be of interest. If L and f represent, respectively, the length of the metre and the number of wave-lengths, λ, contained in it, we may write

$$L = f_1\lambda_1 = f_2\lambda_2 \quad . \quad . \quad . \quad (1)$$

where the subscripts 1 and 2 refer to two different epochs. It is assumed that there is no intrinsic change in L between the two observations. If we also suppose that the frequency of the light, ν, has remained constant but that c has varied, then

$$\lambda_1 = \frac{c_1}{\nu},\ \lambda_2 = \frac{c_2}{\nu}, \quad . \quad . \quad . \quad (2)$$

whence

$$\frac{f_1}{f_2} = \frac{c_2}{c_1}. \quad . \quad . \quad . \quad (3)$$

Since the figures quoted by Mr. de Bray show a decrease in c of about 200 km./sec. between 1902 and 1928, an amount many times larger than most of the indicated probable errors, there may be a real difficulty. With this in mind, it is of interest to see what can be obtained from equation (3). So far as I am aware, there have been two determinations of the standard metre in terms of the red cadmium wave-length, and, quite recently, a similar measurement of the standard yard, by Tutton.[1] The observations on the metre, quoted by Tutton, are

Michelson . . .	1,553,163·50 (f_1)	1892
Fabry, Perot, and Benoit	1,553,164·13 (f_2)	1906

During the interval of fourteen years c would have changed by something like 1/3000, if its present apparent rate of decrease were constant. The difference in the two values of f is, however, negligible, and, moreover, Tutton's own measurements on the yard, when converted to the metre by a factor obtained by non-interferential methods, very strongly support the conclusion that the number of wave-lengths of a given line contained in a given length does not vary with the time.

Thus, taking all the observations at their face value, the situation is that $f_1 = f_2$ while $c_1 \neq c_2$. From these it follows that ν must depend on the time in a manner such that $c_1/\nu_1 = c_2/\nu_2$. Since in classical dispersion theory the index of refraction depends on the ratios of the frequency of the incident light to the natural frequencies of the charges in the body, this last relation might be expected to give rather curious results when observations are made from time to time with a prism spectrograph. None, however, has been reported.

If c does ultimately turn out to be constant, it will be important to investigate the discrepancies between the values hitherto published, in order that they may be used in the final mean. On the other hand, if c depends on the time, we may not unreasonably expect such a variation to appear in experiments other than those which give direct measurements of the velocity.

Climate of Southern Rhodesia

A NOTE on the "Climate of Southern Rhodesia" appears in NATURE of April 2, page 515, based on the Annual Report of this office for the year 1929–30. This notice of our work is much appreciated, but we regret that "E. V. N." has based a revival of the 'south-east trades' theory on the published rainfall maps.

Forecasts based on daily weather maps have been issued by this office for the last ten years. The general rains are of monsoonal character and are associated with the onset of north to north-easterly winds between the semi-permanent high of the Moçambique Channel and the equatorial low in the west.

Recent extension of the weather map has indicated that these winds traverse the tropical portion of the Indian Ocean. The humid north-easterly winds are interrupted from time to time by the invasion of cold air from the south-east in front of a high advancing up the east coast. The zone of discontinuity has marked frontal characteristics, and its passage is accompanied by squalls and thunderstorms, frequently succeeded by drizzle. These highs usually become stationary with their centres near 20° S. latitude, and give spells of fine weather, with light east winds. Apart from the precipitation at the discontinuity formed by the onset of the south-east winds, the rain associated with these winds is purely orographic and small in amount.

The presence of tropical cyclones near Madagascar is usually associated with a diminution of rain in Southern Rhodesia, apparently due to the interruption of the rain-bearing air currents, but a local cyclone which created havoc at Beira in 1929 was undoubtedly the prime cause of a period of heavy rain so far inland as Livingstone.

NOEL P. SELLICK
(Meteorologist).

Irrigation Division,
Department of Agriculture,
Salisbury, Southern Rhodesia,
April 23.

I HAVE read Mr. Sellick's letter about the rainfall of Southern Rhodesia with great interest. It was certainly not my intention to revive a theory of the origin of Rhodesian rainfall that has been disproved. My source of information was Kendrew's "Climates of the Continents" (1922). Kendrew makes a statement (p. 72 of that work) that implies that the monsoonal indraught in the South African summer is fed by the south-east trades, for he refers the moisture to evaporation over the South Indian Ocean. The case against this, it appears, rests upon a consideration of the trajectories of the inflowing air streams and not on the geographical distribution of the normal summer rainfall, for the ordinary diminution of rainfall (after elimination of the orographical factor) with distance from the coast would presumably be shown, whether the indraught were an eddy in the south-east trades or an eddy in a north-west current representing deflected north-east trades that have crossed the equator. Kendrew admits that in summer the north-east trades reach the north-west of Madagascar as north-west winds. The extended charts referred to by Mr. Sellick evidently show that these are then drawn into Southern Rhodesia during the monsoon. It is hoped that this important fact will be mentioned in future works on climatology. E. V. N.

Spectrographic Observations of Infra-Red Lines in the Auroral Spectrum

I HAVE read with great interest Prof. L. Vegard's recent communication[1] on this subject, in which he reports that in the auroral spectrum in the infra-red he has found two bands, a strong one at λ7883 A. and a weak one at λ8095 A., with sharp edges towards longer wave-lengths. Prof. Vegard considers that if the auroral green line is to be identified with the oxygen line at 5577 A., it is expected that other oxygen triplets, 7772-74-75, 8233-30-22, 7952-50-47, and 7481-79-77, will appear in this region, but none of these could be identified with the observed auroral lines. Taking into consideration the high intensities of these two bands, and the emission of the second positive bands of nitrogen in the auroral spectrum, he has interpreted these two bands as the appearances of the first positive bands of nitrogen with the special distribution of intensity.

In the course of investigations on the distribution of the intensity in the α-bands of active nitrogen, I have studied also the distribution of the intensity in the first positive bands in the case of passing an electric discharge of very weak current through nitrogen at low pressure and cooled with liquid air, and it was found that the bands due to the transitions from the initial levels which correspond to the vibrational quantum numbers 7 and 6 in the $B(^3\pi)$ state of nitrogen molecules are enhancingly emitted in the first positive bands. With reference to the results above described, the two bands which Prof. L. Vegard has found seem to be identified with the bands at 7896-80-58 ($7 \rightarrow 6$) and 8047-30-08 ($6 \rightarrow 5$) respectively in the first positive bands of nitrogen, though there are some differences in the wave-lengths. It may be considered that the experimental conditions above described are very close to those in the aurora with respect to pressure, temperature, as well as the conditions of weak excitation, and as a consequence of the Franck-Condon principle there will result fair concentrations of the excited nitrogen molecules in the vibrational levels corresponding to the quantum numbers $v' = (-11)$, 7 and 6 in the $B(^3\pi)$ state. Therefore it is expected that in the infra-red region the bands due to the transitions ($7 \rightarrow 6$) and ($6 \rightarrow 5$) will be emitted intensely, and these two bands will be identified with the bands which Prof. Vegard has reported and nicely interpreted ($n_1 \rightarrow n_2 = 7 \rightarrow 7$).

The detailed description of the experimental results will be published shortly elsewhere.

Liquid Carbon Dioxide in the Depths of the Ocean

A PARAGRAPH in NATURE of April 23, p. 607, refers to a paper in which the Russian geologist W. Vernadsky states that carbon dioxide is in a stable liquid state in the depths of the ocean. He assumes that this may be the reason why there are no appreciable amounts of plankton below about two hundred metres. It must be remarked that the carbon dioxide is physically dissolved in the sea water, therefore the laws of gases do not apply. The pressure would only be of importance if springs of carbon dioxide exist on the bottom of the deep sea; in this case the carbon dioxide would issue as a liquid but quickly be dissolved by the water. According to the results of the *Meteor* expedition, it seems highly improbable that such sources of carbon dioxide are present in the ocean—at least, in the Atlantic.

However, the pressure causes an effect on the carbonic acid. The dissociation of this acid rather increases with the greater depths. The deep water is more acid than the shallower, provided the carbon dioxide content is the same.[1]

Concerning Vernadsky's conclusions, it may be mentioned that Hentschel[2] found considerable amounts of phytoplankton down to several thousand metres. Further, that the oxygen in the bladder of deep-sea fishes may be the result of a decomposition of liquid carbon dioxide seems quite impossible in view of the energy needed for this reaction.

Meteorite Craters

THE very interesting article by Dr. L. J. Spencer on "Meteorite Craters", in NATURE of May 28, suggests a possible explanation of the fact that, while the bedding of the surrounding country may be horizontal, the strata exposed in the inner walls of the crater usually dip radially outwards from the centre.

The air photograph of the Cañon Diablo crater reproduced in the article bears a close resemblance to the well-known 'splashes' produced at the surfaces of armour-plate by the impacts of projectiles. The analogy between such 'splashes' and those of drops falling into liquids was pointed out by Roberts-Austen in *Fielden's Magazine* of August 1899.

It may be of interest to recall that A. M. Worthington was the first to synchronise photographic records with the movements occurring during the 'splash of a drop'. His classical work formed the subject of a discourse at the Royal Institution in May 1894.

Research Items

British Hanging Bowls.—In *Antiquity* for June, Mr. T. E. Kendrick has published a study of the hanging bowls of bronze with special reference to their position in the cultural history of Britain. Hanging bowls, already known in Britain in La Tène times, returned into fashion in the second half of the Roman period. An approximate date of A.D. 400 is suggested for the hiding of a hoard found at the Romano-British settlement at Irchester. The most decorative bowls are those fitted with escutcheons in the form of enamelled discs. They may be grouped under three sub-headings: (i.) The 'Romanising' series; (ii.) the 'ultimate La Tène' series; and (iii.) the 'developed trumpet-pattern' series. In the Romanising series, the escutcheons show the inspiration of classical ornament and come down possibly to a date not later than 500 B.C. The 'ultimate La Tène' series is the work of craftsmen who were still resolutely Celtic, and had no sympathy with Roman and contemporary continental design. They represent the continuation of the native enamel work of the north. The Barlaston bowl and the Northumberland escutcheons, which belong to this class, cannot be later than A.D. 300. The contrast with class iii., the 'developed trumpet-pattern' series, is very striking. Here the work is primarily concerned with the modifications of the late Roman pelta trumpet-patterns, which are transformed with all the grace of the British artist. These decorative designs later became the stock-in-trade of the illuminator; and it is suggested that they are not the renaissance of an ancient Celtic art, but an independent Celtic experiment which developed a borrowing from late Roman art. Although the bowls are for the most part found in Saxon graves, they were loot; and the Saxons probably contributed nothing to their manufacture.

Palæolithic Art in the Grotte d'Isturitz.—M. le Comte Réné de Saint-Périer has described (*L'Anthropologie*, **42**, Nos. 1-2) two remarkable examples of palæolithic art which have been discovered in the course of excavating the inner chamber of the Grotte d'Isturitz (Basses Pyrénées). They are derived from a lower Magdalenian stratum without harpoons, above which are, possibly, two Magdalenian strata in which harpoons appear. One of the objects is a sculptured bear in limestone, 51 mm. high by 20 mm. thick. Great care has been given to the proportions of the figure. The limbs have been broken off by an ancient fracture almost level with the body. The sculpture is charming in its correct representation of the characteristic modelling, attitude, and expression of what is clearly *Ursus arctos* and not *Ursus spelæus*. The second object is of bone, 120 mm. by 20 mm. by 2 mm. thick. The ends are broken off. It is engraved on both sides. On one side is a bison of fierce aspect, realistically engraved to show the distribution of the hair. Two harpoons or barbed javelins are in its flank, and two columns of hot breath issue from its nostrils as it follows another bison, of which the hind-quarters have just survived the fracture. On the other side, two crudely engraved human figures, male and female, appear, which in their relation one to another are unique in palæolithic art. The woman, whose head is broken off, is fat but not enceinte. Hair is shown freely distributed over the abdomen, thighs, and the one breast visible. Bangles encircle one ankle; a barbed javelin head appears on the right thigh; and the arms are raised as if in prayer. The man, of whom half remains, is in the same attitude with arms upraised and face looking up towards the woman above his head. He wears necklaces and bracelets.

Identical Twins reared Together.—The studies of Dr. H. H. Newman on twins reared apart (see NATURE, May 7, p. 692) are to some extent supplemented by Mr. Harold D. Carter's account (*J. Heredity*, vol. 23, No. 2) of identical twins reared together. In Case 1—boys of fourteen years of age—one of them reads more and appears somewhat brighter; but it is not clear whether he is brighter because he reads more, or reads more because he is brighter. The Siamese twin girls aged fourteen years studied by Dr. Helen Koch were found to differ distinctly in intellect and achievement, but the differences are less than in most twins. Such differences are regarded as innate and not environmentally produced. In Case 3 (brothers of sixty years) the twins were more unlike than in Case 2 (sisters of thirty-eight years), although the similarities of environment were greater in the former case. In Case 2, the difference in ability was in favour of the twin with less favourable environment, again suggesting that a difference in mental endowment was determined internally rather than externally. In all these cases the twins were extremely alike, often mistaken for each other, and their finger patterns almost or quite identical.

Control of Leather-Jackets.—Among other articles of practical value and interest in the sixth issue of the *Journal* of the Board of Greenkeeping Research is one by R. B. Dawson, which deals with the question of the control of leather-jackets, the larvæ of *Tipula paludosa* or daddy-long-legs, which may be very destructive on golfing turf. The subject is introduced by an account of the life-history and habits of the insect, knowledge of which is essential if suitable control methods are to be found. For small, level areas, the practice of spreading tarpaulins or rubber mats overnight on grass which has been soaked with water often proves successful, as the larvæ collect at the surface. For larger areas, applications of a chemical larvicide is more practicable, and a 64 per cent emulsion of orthodichlorobenzene is specially recommended. This has proved a thoroughly trustworthy method of control, and only temporarily discolours the grass. Full instructions for making and using this emulsion are supplied, the cost of the treatment being 8*s*.-12*s*. per 500 sq. yards. Other methods involving the use of materials such as naphthalene, paris green, ammonia solutions, etc., may also be effective in controlling the pest, but they are less unreservedly recommended, as they are apt to be unreliable, and in some cases have poisonous properties.

Characteristics of Home-grown Timbers.—With the introduction of research into the mechanical and physical properties of timbers, it has been necessary not only to standardise the meaning and application of technical terms and the methods to be followed in the tests, but also to compile and publish the results in rather complicated tabular statements. In order to place this information in a form more readily accessible to those who wish to have a general comparison of our home-grown timbers in their relative strengths as developed in various types of construction and manufacture, the Forest Products Laboratory has issued *Bulletin* No. 12, entitled "Some Characteristics of Home-grown Timbers" (pp. v + 11 + 9 plates. London: H.M. Stationery Office, 1931. 2*s*. net). The publication deals with the characteristics of eight home-grown hardwoods and five softwoods: oak, ash, beech, common elm, Dutch elm, wych elm, chestnut, and poplar (*P. serotina*); Corsican pine, Douglas fir, European larch, Scots pine, and silver

fir. The strength properties of the species are compared by means of diagrams in which the height of a column denotes the degree of the property attained by the particular timber, as compared with the same property in home-grown oak; these diagrams are explained by notes, which give not only the applications of the various strengths and other properties depicted, but should also afford considerable assistance in the selection of timber for a given purpose. Besides the general comparisons above mentioned, there are graphs which show the influence of the specific gravity of a timber upon its relative strength, as well as diagrams indicating the relative shrinkages which take place in the timbers. These last are of particular interest in the case of woods for panelling, flooring, patterns, and other uses where shrinkage and the 'working' of the timber with change in atmospheric humidity are of considerable importance.

Earthquakes, Fisheries, and Flower Fall.—Prof. T. Terada has shown that there exists a curious relation between the numbers of earthquakes in the Idu peninsula and the numbers of fishes caught near the northern end of Sagami Bay (*Proc. Imp. Acad. Tokyo*, vol. 8, pp. 83-86; 1932). During the spring of 1930, swarms of earthquakes occurred in the neighbourhood of Ito on the east coast of the peninsula (NATURE, vol. 126, pp. 326, 971). It was found that the epochs of abundant catches of horse mackerel (*Caranx*) at the Sigedora fishing ground coincided very nearly with those of the earthquakes. This result led Prof. Terada to compare the numbers of fishes caught in the six years 1924–29 with the numbers of felt and unfelt earthquakes in and near the Idu peninsula. For the year 1928, the parallelism of the two curves was very close, though in other years it was less conspicuous. During 1928, the curve representing the numbers of immature tunny (*Thynnus*) caught shows a remarkable similarity with the horse mackerel and earthquake curves. In another paper (*Bull. Earthq. Res. Inst.*, vol. 10, pp. 29-35; 1932) Prof. Terada points out that, though the daily numbers fluctuate, the time-distribution curve of the Ito earthquakes resembles on the whole the probability curve, and he shows that the daily number of falls of camelia flowers follows a similar statistical distribution.

Meteorology of the North and South Atlantic.—Continental meteorologists have in the past played an important part in the collection of information about the weather over the Atlantic. The long series of daily synoptic weather maps for Europe and the Atlantic prepared by the Danish and German Admiralties before the War were for many years without rival for completeness, and have been of constant assistance to the forecasting staff of the Meteorological Office, Air Ministry, in the study of large scale air movements and their effect upon British weather. The last section of a new contribution, of a more statistical nature but dealing with an almost equally large area—namely, the North and South Atlantic—has just been received. It has been compiled under the direction of Prof. E. Van Everdingen, the director of the Dutch Meteorological Service, and summarises about seven million observations of oceanic current, wind, barometric pressure, temperature, and cloud, covering the three months September, October, and November for the years 1870–1925, the other quarters having already been dealt with. It takes the form of a series of large charts with explanatory matter and tables (*Pub.* No. 110, Koninklijk Nederlandsch Meteorologisch Institut). It is scarcely necessary to say that such a compilation is of immense value to those engaged in a study of world weather, and that it will be a mine of information for future compilers of climatological handbooks and treatises. It includes detailed studies of the more important disturbances which are of danger to navigators of the Atlantic, such as the cyclonic depressions of the North Atlantic, the West Indian hurricanes, and the 'tornadoes' or storm squalls of the West African coasts. These last, it should be mentioned, differ greatly from the American tornadoes, which are much more violent, but fortunately also individually affect much smaller areas and are in the main land phenomena outside the scope of this work. Assistance in the supply of data has been given by the French, German, and English meteorological services; this is therefore the concluding section of a great international undertaking.

Vacuum Distillation.—In a paper on vacuum technique (*J. Franklin Inst.*, Feb. 1932), Dr. K. Hickman of the Kodak Research Laboratories has directed attention to the serious errors which may occur in the measurement of the saturation vapour pressure of liquids when that pressure is of the order of a millimetre of mercury. Unless the vapour pressure is measured close to the thermometer which gives the temperature, the correction for the drop of pressure from thermometer to manometer becomes of the order of the pressure to be measured. Dr. Hickman enlarges the head of the rectifying column, places the thermometer in the enlargement, and either measures the pressure there directly or by the aid of a column of the condensed liquid in a U-tube between the enlargement and the manometer. With this arrangement, he finds that the relation between log (pressure) and the reciprocal of the absolute temperature continues to be linear down to very low pressures.

Spectrum of Lithium Hydride.—A further analysis of this spectrum, which is one of considerable complexity, is given by G. Nakamura and T. Shidei in the *Japanese Journal of Physics* (**7**, p. 33). In their previous work, a large number of faint lines were not classified; in the present investigation, it has been found possible to include many of these in a band system which is attributed to the hydride (Li^6H) of the lighter and rarer lithium atom, but the very curious feature emerges that the relative intensities of the lines associated with Li^6 and Li^7 respectively vary with the conditions under which the spectrum is taken. This is in accord with Dempster's work on lithium with the mass-spectrograph, but not with that of Bainbridge. This spectrum has the further point of interest that it arises from two of the lightest atoms, so that it is not impossible that it may serve to check a quite full quantum theory of their combination; the theory of the normal state of the molecule has already been developed in some detail by Hutchisson and Muskat in the first May number of the *Physical Review*.

The Electron Microscope.—It has been known for many years that a divergent pencil of electrons can be refocused by a magnetic field. More recent investigations, which are summarised by E. Brüche and H. Johannson in *Die Naturwissenschaften* (May 20), have shown that an electric field can act similarly, and, in fact, that a complete system of electron-optics exists, with reflecting and refracting surfaces in the ordinary sense replaced by regions of field acting upon moving electrons. Brüche has demonstrated the action visually by photographing beams of electrons passing through 'electron-lenses' in gas at low pressure. In this article an account is also given of an electron-microscope which is likely to be of use technically; it is constructed much on the principle of an ordinary microscope, but with electron lenses, and shows a much enlarged image of a small electron-emitting

surface by the fluorescence of the points of impact of electrons which have passed through the 'microscope' on to a screen. The whole arrangement is like a small optical bench set up in a vacuum vessel. Two examples of its application are given: the first, a 150-fold enlargement of a badly coated oxide cathode, showing clearly the patchy nature of the active surface, which could not have been inferred with such certainty from an ordinary optical study; and, secondly, a set of enlargements (× 65) showing the migration and final disappearance of the active centres on an overheated coated cathode. It would appear to be possible in principle, although scarcely in practice, to obtain pictures of the electron-emitting areas on the surface of the sun from experiments on the streams of charged particles which produce the aurora.

The Wassermann Test.—Many variations of the Wassermann test have been described, with the view of increasing its sensitiveness and rendering it more specific, thus eliminating the doubtful reactions, which are of no value to the clinician. E. J. Wyler has recently described an improvement in his routine test, by which more accurate results can be obtained (Reports on Public Health and Medical Subjects, No. 67. London: H.M. Stationery Office, 1932. 4*d*. net). In the test, the suspected serum, previously heated to 55° for 30 min. to inactivate complement, is mixed with complement (guinea-pig's serum) and antigen (alcoholic human heart extract, 3 parts, with 2 parts of a 1 per cent alcoholic solution of cholesterol) and incubated at room temperature for 30 min. and then at 37° for 30 min. A standardised suspension of sheep's red blood cells sensitised with at least six doses of hæmolytic immune body is then added; hæmolysis occurs quickly when the suspected serum does not come from a case of syphilis, but is absent or incomplete when the patient has suffered from syphilis which has not been completely cured—in other words, the Wassermann test is positive. In all tests, control tubes are put up containing serum and complement but no antigen: lysis of the sensitised red cells should be quick and complete, when added at the end of the preliminary incubation, in the presence of three minimal hæmolytic doses of complement. The variations in the method concern the amounts of complement, antigen, or serum added and the type of antigen used. The author has found that the greatest sensitiveness is attained when the amount of serum is increased from three up to five times that normally used, whilst variations in the quantities of the other reagents gave less satisfactory results. 20 per cent of sera which were negative or doubtful by the routine test gave a definite positive response with the new method. In non-syphilitic sera, there were no false positives and only 2·6 per cent were doubtful: with the ordinary test, 9·3 per cent were doubtful. The new method is also more sensitive than the flocculation or Sigma test, which itself is more sensitive than the routine Wassermann test.

Astronomical Topics

Two New Comets.—A telegram from the I.A.U. Bureau, Copenhagen, announces the discovery of a new comet by Mr. Newman, who gave the following position for 1932·0:

U.T.	R.A.	N. Decl.
June 20d 4h 49·4m	15h 37m 16s	7° 56′

Daily motion, −2m 8s, +44′: Magnitude, 13·0

From observations on June 1, 7, and 20, Whipple and Cuningham have determined the following elements:

$$T = 1932 \text{ Sept. } 27 \text{ U.T.}$$
$$\left.\begin{aligned}\omega &= 73^\circ\ 50'\\ \Omega &= 244\ \ 50\\ i &= 76\ \ 50\end{aligned}\right\} 1932{\cdot}0$$
$$q = 1{\cdot}57$$

The following ephemeris is for 0h U.T.:

	R.A. (1932·0).	Decl. (1932·0).
June 30	15h 20m	+14° 0′
July 4	13	16 10
8	15 8	18 10

The following observations have been made by Dr. W. H. Steavenson with his reflector at West Norwood. Equinox 1932·0:

	R.A.	Decl.
June 21d 23h 9·7m	15h 34m 3·1s	+ 9° 4′ 42·6″
22 23 9·5	15 32 10·2	+ 9 43 48·0
25 0 19·3	15 28 26·5	+10 51 16·9

The B.D. position of the comparison star, B.D. + 9° 3075, was used. The comet preceded it by 1·0s, and was 7′ 19·1″ north of it. The diameter was 1′, and there was a nearly stellar nucleus of magnitude 12. The approximate daily motion indicated is about −1m 41s, +38′. The comet is well placed for observation.

A Reuter's telegram from Wellington, New Zealand, announced the discovery of a comet of the 10th magnitude by the New Zealand Government Astronomer; the message was dated June 23, but the discovery was presumably on June 22 by U.T.

R.A. 0h 15m decreasing.
S. Decl. 84° 36′ decreasing.

This makes the seventh cometary discovery of the year, including the van Biesbroeck object of March 6, which was not seen again. Two of the seven (Grigg-Skjellerup and Kopff) were the returns of periodic comets; the others appear to be new comets.

The Coming Total Solar Eclipse.—An article by Dr. A. V. Douglas (*J. Roy. Ast. Soc. Canada*, May–June) gives information about the arrangement of parties to observe this eclipse, and suggests how amateurs can help. Observations of the exact limits of the path of totality are suggested; this was satisfactorily carried out in the eclipse of January 1925; also observations of the shadow-bands, of the fall of temperature, and of the degree of illumination during totality (by seeing at what distance small type can be read). It is also suggested that wireless experts may study the effect of the eclipse on radio-transmission. Dr. Douglas gives a list of coming totalities; but, curiously, as in several lists, the favourable eclipse in Norway on July 9, 1945, is omitted; this is a return of the British eclipse of 1927, but with a higher sun and longer totality. Prof. C. A. Chant, in the same journal, gives details of the location of the various parties of observers. Dr. J. Jackson and Mr. C. R. Davidson from Greenwich, with Dr. Knox Shaw, are going to Parent, north of the St. Lawrence; Prof. F. J. M. Stratton to Magog, on the south side of the River; Profs. A. Fowler and H. Dingle will observe from McGill University, near the edge of the belt of totality. A party from the Royal Astronomical Society will go to a station in Maine. Nearly all the great American observatories are sending parties, and others are going from Japan and Pulkovo. Given fine weather, it should be one of the best observed eclipses on record. A map of the portion of the track from the St. Lawrence to the Atlantic is given in the B.A.A. Handbook for 1932.

New Methods of Research in Aeronautics

THE twentieth Wilbur Wright memorial lecture, delivered before the Royal Aeronautical Society by Mr. H. E. Wimperis, on May 26, under the above title, is of twofold interest to scientific readers. It gives an account of the work now in progress in aeronautical research. It also includes a more abstract discussion upon the aims of aeronautical research in Great Britain, the difficulties that confront it—not the least of which are those of finance—and the methods by which it is hoped they will be overcome.

Mr. Wimperis began by commending the methods of the Wright brothers as being the soundest in scientific research. They "made thousands of tests . . . and tabulated thousands of readings". Few persons actually engaged in research will quarrel with that commendation. The paper then describes the organisation of aeronautical research in Britain, and pays tribute equally to the progress made by the scientific workers and to the aircraft industry's ability in utilising information so obtained. Mr. Wimperis scarcely gives full credit to Britain for its relative contribution to the world's aeronautical knowledge; in fact, he more than once apologises for the inadequacy of the equipment, both in use and proposed. It is hoped to be able to use this limited amount of apparatus for the unhindered solution of various problems, by skilful adaptation, and extending results so obtained upon a basis of mathematical and physical reasoning.

The new British compressed air tunnel will be able to obtain a Reynolds number 1·93 times that of the only other one in existence in the U.S.A., by working at an air pressure of 25 atmospheres. The solution of many of the problems met in the course of the development of this apparatus has been very materially helped by the full and free communication of all available information from the National Advisory Committee for Aeronautics in America. Incidentally, the policy of delaying the building of this tunnel until the U.S.A. Committee had fully explored theirs has been fully justified, and the truly international aspect of scientific research, when unhampered by political affairs, is emphasised.

The large wind channel to be erected at the Royal Aircraft Establishment at Farnborough is to be only 24 ft. diameter, against the 60 ft. × 30 ft. cross section of a similar one in America, and will use 2000 h.p. for air propulsion, as compared with 6500 h.p. in the large American tunnel. It will thus be cheaper both in first cost and running expenses. A 24-ft. tunnel can be used to investigate all problems that must inevitably be so done, that is, those incapable of being attacked by direct full scale experiments during flight. These are all connected with the central part of an aeroplane, principally the cooling of engines, resistance of the body and its parasitic parts, and the investigation of airscrews. Problems upon the behaviour of the actual wing structure can be, and have been, successfully measured in full scale flight on a special Parnall research monoplane, and such results can be added to those found in the tunnel for the more complex parts around the body.

A vertical wind tunnel for the investigation of spinning is also described. The air in this moves upwards, so that the spinning model, while falling relative to the air, is actually kept in the plane of observation and measurement by the operator. These experiments raise extremely complex problems upon the validity of transferring results from models of one size to another, or comparing results at different speeds, because of differences in mass, moments of inertia about various axes, etc. The effect of the sudden movement of control surfaces is reproduced by a delay action mechanism incorporated in the model.

The visual examination of air flow has obvious uses in aeronautical research. This is accomplished by the introduction of smoke from titanium tetrachloride for slower speeds. For higher speeds, shadowgraphs are taken from air heated by passing it across an electrically heated wire and viewing the model in its wake, either stroboscopically or photographically. When conditions are analogous, water can be used, and the motion examined either by watching illuminated oil bubbles or by focusing a microscope upon 'objects' in the water.

Experiments upon the suppression of noise are of interest not only for themselves, but also for the necessary development of the technique of the measurement of noise in 'decibels'. Considerable progress has been made in the insulating of the interior of an aircraft cabin from noise, but not so much upon the suppression of the noises at the source.

An ambitious programme of work on flying boat hulls and floats is outlined for the new tank at the R.A.E., Farnborough. Although the size of the tank is being limited, it is hoped to investigate all that is necessary by examining the behaviour of the model during the inevitable acceleration and deceleration in each run. It so happens that these are the two periods of greatest interest to designers, as the only parts of a seaplane's normal travelling life on the water are spent in either of these operations. Here again there will be considerable mathematical difficulties concerned with problems of mass, acceleration, and dynamical similarity.

The address concludes with a tribute to all those who have been concerned with the work of producing and handling machines for the Schneider contest. Mr. Wimperis expresses his satisfaction that these competitions have now automatically ceased, as the risk to the flying personnel was out of all proportion to the value of any results likely to be obtained from the mere further increase of flying speed alone. Nevertheless, the value of the technical progress that has been made in this respect is not to be underestimated.

Early Maya Culture in Northern Yucatan *

COBÁ, if only on account of its size, is one of the most important centres of culture in the Maya area of Central America. If, and when, its ruins are excavated, it is not improbable that it may prove crucial in the solution of a number of obscure problems connected with early Maya colonisation in northern Yucatan. Since its ruins were discovered in 1926 by Dr. T. W. Gann—it was not then known that it had been visited by Teobert Maler in 1891—five further expeditions of the Carnegie Institution have been engaged in exploration and survey work on the site.

Cobá, which is situated in the Mexican province of Quintana Roo in the north of the Yucatan Peninsula,

* A Preliminary Study of the Ruins of Cobá, Quintana Roo, Mexico. By J. Eric Thompson, Harry E. D. Pollock, and Jean Charlot. (Publication 424.) Pp. vii+218+18 plates. (Washington, D.C.: Carnegie Institution, 1932.)

about 100 miles east of the ancient Maya city of Chichen Itzá, and has the largest assemblage of buildings, with the exception of Tikal, in the Maya area, is one of the few sites of which the ancient name is still known to present-day Indians. Vestiges of ancient cult and ritual still linger on before its stelæ; while the deities of Cobá are venerated in bee-keeping and first-fruit ceremonies in distant villages, where the inhabitants assuredly have no knowledge of the present-day ruins of Cobá.

The site of Cobá was especially favourable for Maya colonisation, owing to the propinquity of an ample supply of surface water in a chain of lakes, and a plentiful rainfall, which fostered the growth of vegetation and the pursuit of agriculture.

The area which has been mapped up to the present covers 9 km. from north to south and 5 km. from east to west.

To the south the ground is still unexplored, and more ruins may yet be found there. Of the surveyed area, the northern part is literally covered by ruins. Between the main groups of Cobá and Nohoch Mul there is an almost unbroken succession of mounds, culminating in a group of considerable importance associated with Nohoch Mul. The shores of Lakes Cobá, Macanxoc, and Sacakal are surrounded by mounds which, excluding those of the last-named lake, form one great site, 3·5 km. by 2 km.—certainly one of the largest in the Maya area.

One of the most striking features of Cobá is the network of artificially constructed raised roads connecting the various groups about the lakes and running off in all directions to distant sites. One of these leads to Yaxuná, a distance of 100 km., terminating only 20 km. from Chichen Itzá. These roads are raised above ground-level and, for the most part, run perfectly straight. They are built of vertical slabs of roughly dressed stone, with an inside fill of large stone, covered with smaller stone. A fine plaster surface has now weathered away.

Broadly speaking, the ruins of the Cobá district fall into two classes of construction, a superior and an inferior, which, while not differing radically, exhibit certain variations in quality of workmanship and design. A preponderance of the buildings shows a closely connected court type of assemblage with a fixed scheme of orientated groups. The Macanxoc groups, however, abandon the orientation. Such compact assemblage finds its most common expression in the Peten region of Guatemala at Tikal, Nahum, and similar sites; while Uaxactun shows a tendency to separate groups, though still with an orderly scheme of arrangement of buildings, definitely related to one another. Notwithstanding the difficulty of drawing parallels between Cobá and other areas, there are certain distinctly marked affinities with the 'Old Empire' centres to the south, which is borne out by the analysis of the art of Macanxoc, for which Mr. Jean Charlot has been responsible. At the same time, there is sufficient evidence of independence in development, especially in the unique character of the complicated system of artificially made roads, to suggest a long period of growth locally, and even possibly several occupations.

At one time or another, no less than fifty monuments have been discovered at Cobá. Of these, twenty-four are carved, twenty-three being stelæ and one an altar. The stelæ at Cobá and Macanxoc are placed in 'shrines'—stone structures consisting of a platform with back walls and short projecting side walls. Structures of this type have not been reported from any other Mayan site. It is possible that they were roofed over with thatch.

Some of the stelæ are dated in the Maya notation. Of these, the earliest is of some importance in its bearing on the spread of Maya colonisation into northern Yucatan. Hitherto it has been held, on the authority of a statement in the Book of Chilam Balam, that Chichen Itzá marks the first Maya intrusion into the area. This is dated at an equivalent in the Christian system of A.D. 452; but a dated monument at Cobá gives a date equivalent to A.D. 353, making this site at least a hundred years earlier; while the evidence of the development of style in architecture and art suggests that the original settlement was considerably older. A series of dates is now known from the three cities of Tuluum, Ichpaatun, and Cobá, ranging from A.D. 314 to 353, which points to a movement along the east coast of Yucatan, of which the terminal was Cobá, and the place from which it originated in the 'Old Empire' area of Peten, possibly at Naranjo, though on the evidence of affinities in art, Mr. J. Charlot thinks it possible that the site of origin may still await discovery.

Sunspots, Planets, and Weather

ONE of the most interesting problems of meteorology is the relation between sunspots and terrestrial weather. In most parts of the world, including the British Isles, the relation is too complex to be readily demonstrable, and the number of unknown factors too great for it to be of use in forecasting, but in a few areas, for one reason or another, the control by sunspots becomes dominant. Mr. Inigo Jones, Director of the Bureau of Seasonal Forecasting in Queensland, believes that Australia is one of these areas under solar control, and in a recent presidential address to the Queensland Astronomical Society* he quotes a number of examples.

Mr. Inigo Jones carries the problem a stage further, however, seeking beyond sunspots for their causes. The sunspot cycle, striking as it is, is not perfectly regular, and the dates of maxima and minima cannot be forecast exactly. He believes that this cycle is caused by the movements of the planets; it is dominated by Jupiter, which has a periodicity of 11·86 years, but irregularities are caused by Saturn and to a less extent by Uranus and Neptune, and these introduce additional cycles which reduce the average length to 11·1 years. Hence he seeks for the explanation of abnormal weather not only in the sunspots themselves but also in the conjunctions of the planets. Especially important is the conjunction of all four, which occurs at intervals of 164 years and is often associated with world-wide climatic disturbance and severe famines.

The way in which sunspots operate is still a mystery, but there are many indications that the greatest effects take place high in the atmosphere, in the ozone layer, the conducting layers, and the auroral zone, and the surface effects may be of a secondary nature only. Mr. Inigo Jones describes a possible mechanism as follows: "Cyclones to which our heaviest rains are attributable are caused by discontinuities between air masses having different temperature and moisture contents, and it is clear that any upper air changes must accelerate such differences, and further, the fact that sunspots by their emanations disturb the upper air and so suddenly intensify these differences, shows easily how it is that the effect is produced, and at the initiatory or terminal stage of each sunspot's visibility". More prolonged effects may take place through the action of ozone, and investigations which

* "Seasonal Forecasting." Brisbane, 1931.

are now being made into the relations between solar radiation and ozone should throw a great deal of light on the effect of sunspots on weather.

The problem is complicated by terrestrial effects, such as the lag in changes of world temperature caused by the masses of polar ice and by the movements of powerful ocean currents, or the disturbing effects of great volcanic eruptions. All these factors will need to be taken into account before long-range forecasts can attain a really effective precision, but Mr. Inigo Jones gives a number of examples to support his view that in Australia at least the major control of weather is exerted by the sun.

Canned Fruit and Vegetables

THE processes that made the preservation of fruit and vegetables possible were discovered in France more than a century ago, but although numerous canning factories have been in operation in several European countries, America, and parts of the British Empire, it is only during the last ten years that any have been built in England. However, 53 such factories were in operation in this country by 1931.

The quantity of canned fruit imported into England has shown an enormous increase in recent years. In view of this greater demand, the home industry has every prospect of success, provided the grower will produce the right type of fruit and vegetable. To meet this need, the Ministry of Agriculture has published an illustrated bulletin (No. 45) entitled "Fruit and Vegetable Production for Commercial Canning" (London: H.M. Stationery Office, 1*s*. 3*d*.).

Plums are by far the most important tree fruit for canning purposes, the use of cherries being somewhat restricted owing to the tendency of the juice to act on the metal container and the difficulty of finding a suitable variety. As regards the commonly grown soft fruits, the majority may be successfully canned if firm, clean fruit is selected. Up to the present, peas are the only vegetable that has been canned in any quantity, but the possibilities of extending the industry to include other vegetables are indicated.

Production for the cannery is an entirely different proposition from production for the fresh market, and it is essential that the grower should recognise this from the start. On the whole, it would seem most suited to large-scale producers with mechanical methods of cultivation, as regular, standardised consignments are required and costs must be kept as low as possible. From the long experience obtained in other countries, the desirability of contract growing is indicated. Various methods of this system are discussed, but it is evident that special arrangements will need to be worked out to meet the particular requirements of the different crops. Some such methods should, however, do much to promote the development of the industry and give confidence to the growers.

Standardised Preparations of Vitamins A and D

WE are glad to note that British manufacturers have taken full advantage of the recent striking advances in our knowledge of the fat-soluble vitamins A and D and have now available for general clinical use standardised preparations of these highly important substances. The isolation of calciferol (vitamin D) by Dr. Bourdillon and his collaborators has been followed in a remarkably short space of time by its preparation on a commercial basis by British Drug Houses, Ltd., who are to be congratulated on the rapidity with which they have translated a delicate laboratory process to a works' scale. This firm now supplies, under the name of Radiostol Solution and Radiostol Pellets, pure crystalline vitamin D. The solution, the activity of which is such that one fluid ounce is equivalent to fifty fluid ounces of cod-liver oil, is a tasteless preparation of the pure vitamin in oil, while the pellets contain it incorporated in cocoa butter, one pellet being equivalent to a full adult dose of cod-liver oil.

Another physiologically standardised vitamin D product, sold under the brand name of Ostelin, emanates from the Glaxo Laboratories (Joseph Nathan and Co., Ltd.). This preparation, which was originally manufactured in 1924 from cod-liver oil but is now prepared by the carefully controlled irradiation of ergosterol, is also supplied in both liquid and tablet forms. Ostelin liquid, which is standardised to contain 5000 international units of vitamin D per c.c., is tasteless and miscible with water, and can therefore be dispensed in pharmaceutical mixtures. The tablets contain, in addition to 500 units of vitamin D each, neutral calcium glycerophosphate.

More recently the Glaxo Laboratories have also put on the market, under the brand name of Adexolin, a mixed preparation of both vitamins A and D in proportions normal to cod-liver oil. Adexolin is available both as liquid and capsules. The special feature of the liquid, a fluid oz. of which is equivalent in both vitamins to 20 fluid oz. of good cod-liver oil, is that as a result of a special process it is largely free from the objectionable taste of ordinary fish-liver oil concentrates. The capsules have been designed to allow the administration of larger quantities of the two vitamins than is necessary for infants. The prophylactic dose for adults is usually 1–3 capsules per day, but in cases of acute septicæmia complicated by high febrile conditions, so many as 24 capsules per day can, we are informed, be administered with highly favourable results.

University and Educational Intelligence

BIRMINGHAM.—The degree of D.Sc. has been awarded to T. L. Ibbs for various papers on thermal diffusion and the form and field of force of the carbon dioxide molecule and allied subjects.

LONDON.—Mr. J. L. S. Hatton, principal of East London College, has been elected vice-chancellor for 1932–33 in succession to Dr. J. Scott Lidgett, whose term of office expires on Aug. 31. Dr. W. R. Halliday, principal of King's College, has been appointed deputy vice-chancellor for the same period in succession to Canon Douglas.

Prof. D. T. Harris, since 1921 assistant professor in the Institute of Physiology at University College, has been appointed professor of physiology (London Hospital Medical College) as from Oct. 1.

The title of University reader has been conferred on Dr. Evelyn E. Hewer, lecturer in histology at the London (R.F.H.) School of Medicine for Women.

OXFORD.—Among the honorary degrees conferred on June 22 were the following: D.Sc. on Sir John Russell, director of the Rothamsted Experimental Station, and Prof. Willem de Sitter, professor of astronomy in the University of Leyden; D.C.L. on Sir Arthur Salter, recently director of the Economic and Finance Section of the League of Nations.

Sir James Frazer is to deliver the Sir Basil Zaharoff lecture for this year.

THE National University of Ireland is about to enter upon its twenty-fifth year and has signalised the approach of this anniversary and "the special signific-

ance of this year, 1932, in the religious and national as well as international life of the Irish people" by issuing a sumptuous "National University Handbook, 1908–1932". This volume, produced at the Sign of the Three Candles in Fleet Street, Dublin, by Colm O'Lochlainn, a graduate of University College, Dublin, deals with the whole of the academic activities of the University, its three constituent colleges at Dublin, Cork, and Galway, and the recognised national ecclesiastical college of St. Patrick, Maynooth, the relationship of the University to secondary schools, and its social and recreative interests. It includes lists of publications, literary and scientific, by the teaching staff and others holding higher degrees of the University. A chapter on applied science records achievements of four of its science graduates distinguished as research workers: Dr. E. J. Butler, director of the Imperial Bureau of Mycology at Kew since 1920; Dr. F. D. Murnaghan, who has held high appointments as a mathematician in the United States; Dr. T. A. McLaughlin, initiator and managing director during the constructive period of the Shannon Power Electrical Scheme; and Dr. J. J. Drumm, an account of whose remarkable traction battery by Prof. A. J. Allmand, published in NATURE of March 12, 1932, is reproduced in the Handbook. The development of work in applied science in the University has been fostered by the liberal system of travelling studentships, to which the Handbook refers as having provided awards far exceeding any similar facilities offered by other universities in the north-west of Europe.

THE University of London has published, in the form of a pamphlet entitled "New Buildings on the Bloomsbury Site" (18 pp. with illustrations and map), its first proposals for the development of this important site of ten acres behind the British Museum. As frontispiece is a photograph of the model prepared by the architect, Mr. Charles Holden, of the proposed University buildings as seen from Russell Square. The model, without detail or fenestration, gives an impression of a vast building, cunningly devised and working up to a great tower, placed centrally on the site and visible from the main approaches to the new buildings. The tower, as the architect explains, will dominate the group and will serve as the main entrance to the buildings—the administrative building to the south and the library and scholastic sections to the north. "The very orderly disposition of the parts", he adds, "and the strong horizontal character of the whole would give to the mass a classical bias which, together with the rhythmical disposition of the window and door openings and other essential features, may be relied upon to present a neighbourly front to the British Museum and to the surrounding buildings, without the necessity of introducing a columnar treatment." The nearest anatomical parallel to the plan is a spine with vertebræ extending from the tower to the northern extremity facing Gordon Square, the administrative block and the Great Hall forming the head and facing Sir John Burnet's northern extension of the British Museum with its classical columns, the Great Hall being on the Russell Square side of this frontage. The height of the tower is not stated, but it would appear to be about 200 ft.—in no sense a skyscraper, but high enough and impressive enough to give character and unity to the architect's design. The pamphlet includes an account of the history of the University, stressing appropriately its difficulties in finding suitable accommodation for its administrative work; and particulars are given of some of the purposes—university and collegiate—for which the new building will be devoted.

Calendar of Geographical Exploration

July 3, 1798.—The Zambezi and the Cunene

Lacerda left the Zambezi and travelled northwards between Lakes Nyasa and Bangweolo. He had previously explored the Cunene River, and thought that the upper course of the Zambezi might be connected with the Cunene. If this were so, he hoped that the Portuguese might establish cross-country trade between Mozambique and Benguela. Lacerda died in October 1798, and his party returned to Tete in November 1799. Much new information had been gained, but it was soon forgotten and was not available when Livingstone began his travels.

July 3, 1826.—The Arctic Coast of Canada, 1825–26

Sir John Franklin reached the head of the Mackenzie delta. There his party divided into two groups, Sir J. Richardson leading a group eastwards and Franklin going west. Richardson traced 863 miles of unexplored coast between the Mackenzie and the Coppermine Rivers, discovering and naming Franklin Bay, Wollaston Land, Dolphin and Union Strait, and Coronation Gulf. Franklin traced the coast westwards from the Mackenzie for 374 miles to Cape Beechey.

July 4, 1734.—The Siberian Arctic

Pavlov and Muraviev left Archangel to sail for the mouth of the Ob. The expedition formed one of the numerous surveys inaugurated by the Russian Senate, the Admiralty, and the Academy of Sciences in the thirties of the eighteenth century. The impetus towards the geographical survey of Siberia was given by Peter the Great, though the work was not begun until after his death. The boats of the 1734 expedition proved unsatisfactory and a second journey started in 1736, with Malygin in place of Muraviev. Malygin anchored in the sound now named after him; he and his companions mapped the coast of Yalmal and also of Byeli Ostrov. The Ob mouth and the Gulfs of Tas and Gyda were mapped as the result of Ovzyn's voyage (1734–37), while the coast between the Yenisei and the Taimyr Peninsula was explored by Minin in 1738–40.

July 8, 1497.—Vasco da Gama

Vasco da Gama with four vessels left the Tagus River on a journey which filled in the gap of 800 miles of unknown east African coast between the limit reached by Diaz in his 1487–88 voyage and the part known to the Arabs. After a five-thousand-mile ocean journey, he anchored off the west coast of South Africa near the Cape of Good Hope, where, in their eight days' stay, the Portuguese got into touch with the Hottentots. They put into Mossel Bay, and later passed the pillars set up by Diaz, thus entering unknown waters. Natal was passed on Christmas Day. At the Quilimane River they stayed for twenty-two days, suffering much from the low-lying, marshy nature of the coast. At Mozambique they met Arab dhows and learned from them the nature of their further journey along the east coast. The monsoon favoured them and they reached the Indian coast on May 23. The return journey from India to Africa occupied three months, and so many of the men became ill and died that one ship was abandoned in Mombasa; but after that the conditions were favourable and the first ship reached Lisbon in June 1499. Thus was inaugurated the sea route to India, which so profoundly affected the relations between Europe and Asia. Da Gama made a second voyage to India in 1502, and in 1524 was appointed Viceroy of Portuguese India, but died at Cochin on Dec. 24, 1524.

July 9, 1739.—Cape Chelyushkin

A Russian expedition under Lieut. Laptev left the mouth of the Lena, and reached Cape Thaddeus, 76° 47′ N., on Sept. 2. After wintering at the head of Khatanga Bay, Laptev tried to return to the Lena, but his vessel was nipped in the drift ice off the Olonek River. He and his men with infinite difficulty reached their former winter quarters. Thence Laptev and his second in command, Chelyushkin, made sledge journeys to survey the peninsula, and, in 1742, Chelyushkin reached by land the northerly cape which now bears his name.

Societies and Academies

LONDON

Royal Society, June 23.—**R. Whiddington and J. E. Taylor**: The photographic action of slow electrons. The photographic action of electrons (60-300 volts) has been experimentally investigated in the case of 'Imperial Duoplex' films. The formula connecting the blackening with the electron current producing it is of the same form as that known to hold in the case of light but with the constants appropriately changed. The 'inertia' of the film is considerably reduced by oiling its surface before exposure, almost certainly due to fluorescence of the oil under electron impact.—**A. Egerton and G. S. Callendar**: The saturation pressures of steam (170° to 374° C.). The saturation pressures of steam up to the critical point have been measured by a dynamic method using the apparatus designed by the late Prof. H. L. Callendar for the determination of the total heat of steam. The probable accuracy of the results is 1 in 6000. Previous results by statical methods had agreed satisfactorily to 270° C., but departed considerably from each other above that temperature. The present results lie in the region between the former determinations, and should help in the establishment of a precise knowledge of the thermal properties of steam.

DUBLIN

Royal Dublin Society, March 22.—**Henry H. Dixon and T. A. Bennet-Clark**: Electrical properties of oil-water emulsions with special reference to the structure of the plasma membrane (2). Previous work has been confirmed and extended by the use of modified methods and apparatus. It has now been shown that the electrical behaviour of water-in-oil emulsions agrees with that of cells in the several particulars. The sensitivity of a water-in-oil emulsion is raised with the increase of the sodium/calcium ratio. The change of resistance is associated with the elongation in the path of the current of the minute droplets of the water-phase of the emulsion, and inversion is not necessary even for large changes of resistance. The application of the emulsion-theory of the plasma membrane to the results of permeability experiments is discussed.—**Paul A. Murphy and Robert M'Kay**: A comparison of some European and American virus diseases of the potato. In a comparison of a number of European and American virus diseases of the potato undertaken some years ago, it was found that the latent viruses present in American 'healthy' potatoes, as well as in those showing symptoms of various diseases, seriously interfered with the results. The following diseases have been found to correspond on the two continents: leaf-roll, aucuba mosaic, interveinal mosaic, and witch's broom. American leaf-rolling mosaic may have affinities with paracrinkle. No equivalents have been found for six other virus diseases of the potato described in America.

PARIS

Academy of Sciences, May 17 (vol. 194, pp. 1697-1768).—**H. Vincent and L. Velluz**: The cryptotoxic properties of sodium α-oxynaphthoate. Its special action on the diphtheric toxin. Sodium α-oxynaphthoate possesses a selective neutralising action on the diphtheric toxin. The toxin thus neutralised ('cryptotoxin') injected into guinea-pigs gives neither local scar, paralysis, nor general troubles, and gives immunity against the diphtheria toxin.—**André Blondel**: The effect of hysteresis in heating by an oscillating magnetic field.—**Charles Nicolle, J. Laigret, Marcandier, and R. Pirot**: The rat, an animal reacting to benign endemic forms of typhus. The long conservation of virus in the rat. It has been found that the rat can act as a reservoir of the virus of some forms of typhus: for typhus of the Old World type, as distinguished from a second type (Toulons, Athens, and elsewhere), the rat carrying the virus shows no sign of infection.—**Charles Nicolle and L. Balozet**: An attempt to restore the original activity to rabic virus fixed by intracerebral passages on the dog. The experiments have led to an unexpected result. Instead of increasing the pathogenic power, the inoculations have specialised the virulence for the dog's brain and removed from the virus the power of causing hydrophobia except when placed in the brain.—**E. Mathias, W. J. Bijleveld, and Ph. P. Grigg**: The rectilinear diameter of the carbon monoxide molecule. Measurements of the densities of the liquid carbon monoxide and of its saturated vapour at the same temperature for absolute temperatures ranging between 68° and 131°.—**L. Léger and T. Bory**: *Eimeria pigra*, a new juxta-epithelial coccidium, parasitic on *Scardinius erythrophtalmus*.—Henry Perrier de la Bathie was elected *correspondant* for the Section of Botany.—**J. Favard**: The distribution of the points where a nearly periodic function takes a given value.—**de Séguier**: Normalisers of substitutions of order 2 of linear, quadratic, Hermitian, and skew groups in a Galois field of odd order.—**Mlle. Mary L. Cartwright**: Certain integral functions of finite order.—**Basile Demtchenko**: The variation of resistance at low velocities under the influence of the compressibility.—**J. Bion and P. David**: Daytime weakening of mean and intermediate (wireless) waves propagated over the sea. Sommerfeld's formula $d/\sigma\lambda^2$ (d, distance; σ, conductivity of the ground; λ, wave-length) has been hitherto examined by varying λ and d, since the conductivity of the sea is known (10^{-11}). For observations made over the sea, with wave-lengths, 700, 215, and 158 metres, and up to a distance of 1050 km., Sommerfeld's formula was found inapplicable: the empirical formula of Austin, on the contrary, gave figures very close to the experiments.—**J. Sambussy**: The part played by the nature of the electrodes in the conductivity of semiconducting liquids. The current flowing through a column of nitrobenzene depends partly on the material of the electrodes. Some peculiarities in the fall of potential per centimetre were observed with lead, and especially with tantalum electrodes.—**André Lallemand**: The variable paramagnetism of crystallised ferric chloride and the constant paramagnetism of the Fe_2Cl_6 molecule in the gaseous state. Constitution of the molecule Fe_2Cl_6. In the state of vapour, the two atoms of iron have equal magnetic moments, and hence possess the same valency.—**J. P. Mathieu**: Double salts, complex salts, and circular dichroism.—**René Lucas and Marcel Schwob**: The stroboscopic method for the measurement of electrical double refraction.—**Mlle. Ellen Gleditsch and Sverre Klemetsen**: The actinum-uranium ratio in an old uraninite-clevite from Aust-Agder (Norway). In this mineral the actinium found was 3·2 per cent of the

uranium. This agrees with the 2·7 per cent previously found for a Norwegian brœggerite and 3·3 per cent for a Cornish pitchblende.—**G. Reboul**: Radioactive phenomena of the second order and of artificial origin. —**Eugène Cornec** and **Henri Muller**: The lowering of eutectic points.—**M. Bourguel**: The influence of substitutions on the vibration frequency of ethylene compounds. A method of classification of radicals.—**R. de Fleury** and **Benmakrouha**: The utilisation of magnesium alloys.—**A. Sanfourche** and **A. Portevin**: A particular mode of corrosion of austenitic chrome-nickel steels. This steel, which resists completely the action of cold phosphoric acid, is rapidly corroded if this acid contains hydrochloric acid, even in small proportion. The effects of various treatments of the surface on this corrosion has been studied.—**Adrien Karl**: Synthetic willemite. The phosphorescence of natural willemite is usually attributed to the presence of impurities (Ni, Fe, Cu). Synthetic willemite, prepared from highly purified materials, showed a violet phosphorescence: the brilliancy of the phosphorescence was increased by the addition of nickel (1 to 2 per thousand) and copper (0·5 to 2 per thousand).—**P. Süe**: The dehydration of niobic acid.—**Maurice Loury**: Researches on the diaryl-arylethinyl carbinols. Phenyl-*p*-tolylphenylethinyl carbinol, $C_{22}H_{18}O$, and phenyl-*p*-bromophenylethinyl carbinol, $C_{21}H_{15}.O.Br$.—**Georges Lévy**: The preparation of a new ethylnaphthol.—**F. Loewinson-Lessing**: The hortonolite gabbro-diabases of the Siberian trappean formation.—**E. Chaput**: Geological observations in Asia Minor. The Trias of the Angora region.—**Mlle. Elisabeth David**: The presence of Lepidocyclines in the Eocene and their relations with the Lepidobitoides.—**Jules Amar**: The law of renal secretion.—**Philippe Fabre** and **Pierre F. Quesnoy**: The comparative efficacity of cuneiform waves of the second kind and of condenser discharges, with equal initial intensity.—**Michel Taguet**: A new method of studying microbial increase. The method is based on the measurement of the opacity of the culture, by the aid of a photo-electric cell. It is shown that the time-opacity curves for a given organism (*B. coli* in the example given) are superposable. Different organisms give different curves.—**Paul Durand**: Attempts at curative serotherapy of exanthematic typhus. A suitable quantity of the cephalo-rachidian fluid is removed and replaced by the serum. Temperature charts of twelve cases are given, showing the improvement effected.

ROME

Royal National Academy of the Lincei, Jan. 17.—**E. Paternò**: (1) Action of oxygen on sodio-cellulose. The action of oxygen on sodio-cellulose at 100° C. yields only β-cellulose (oxycellulose). At the same time the proportion of carbonate present increases appreciably, the carbon dioxide being formed, together with pentosans, from the cellulose according to the equation, $C_6H_{10}O_5 + O_2 = C_5H_8O_4 + CO_2 + H_2O$.—(2) Maturation of sodio-cellulose. This maturation is undoubtedly an oxidation process, the β-cellulose (oxycellulose) formed being transported through the xanthate to the artificial silk, of which it constitutes a normal component.—(3) So-called regenerated cellulose. In the various transformations it undergoes, cellulose can be regarded as regenerated only when the substances it has absorbed are eliminated by washing with water. If the cellulose has been converted into any compound or has passed into solution or been colloidally dispersed, it cannot be regenerated. For example, when cellulose is separated from its zinc chloride or ammoniacal copper solution, from xanthate or viscose, or from sulphuric, hydrochloric, or phosphoric acid solutions, it does not retain its initial properties. Cryoscopic determinations of the molecular weights of colloidal derivatives of cellulose are inconclusive.—**E. Bompiani**: The contact of two surfaces.—**U. Broggi**: The development of $\sum_{n=0}^{\infty}\left[b_n\left(\sum_{h=0}^{\infty} a_h x^h\right)^n\right]$ in series of increasing powers of x. —**G. Sansone**: The zeros of the polynomial solutions of the equation $(a_1x + a_0)y'' + (b_1x + b_0)y' - nb_1y = 0$ (1). —**F. Conforto**: Considerations on the impulses in isotropic elastic bodies.—**N. Moisseiev**: The law of the resistance to motion of bodies in a pulverulent medium. —**G. Petrucci**: Trains of waves emitted at constant time intervals.—**G. Todesco**: Experimental confirmation of the selective absorption of the Hertzian waves caused by an electronic gas in a magnetic field.—**A. Signorini**: Certain properties of the medium in ordinary elasto-statics.—**L. Infeld**: Remarks on the problem of the unitary theory of fields.—**Dina Lombardi**: Observations on the structure of the nucleus of the larva of *Cricotopus sylvestris* F.

SYDNEY

Linnean Society of New South Wales, March 30.—**G. H. Cunningham**: The Gasteromycetes of Australasia (14). The family Tulostomataceæ. This family is rearranged to contain the genera *Podaxon*, *Phellorina*, *Chlamydopus*, *Tulostoma*, *Queletia*, and *Battarræa*, all of which, save *Queletia*, have representatives in this biologic region, and is divided into subfamilies and tribes. The only representatives of the family found in New Zealand are confined to the genus *Tulostoma*.—**C. P. Alexander**: A review of the Tipulidæ of Australia (Diptera) (1). The historical development of the subject and the general facies and distribution of the Australian fauna are discussed. Keys are given for the subfamilies of the Tipulidæ and for the genera of the Tipulinæ, and the Australian species of *Clytocosmus* are reviewed.—**F. C. Chisholm**: The occurrence of *Atrax venenatus* on the Comboyne plateau. Both male and female examples of *Atrax venenatus* are recorded.—**Rev. H. M. R. Rupp**: Notes on New South Wales orchids (2). A new genus and species of subterranean orchids, allied to the Western Australian genus *Rhizanthella*, is described from Bullahdelah, and notes are given on other species belonging to *Diuris*, *Pterostylis*, *Dendrobium*, *Prasophyllum*, and *Cymbidium*.

VIENNA

Academy of Sciences, March 10.—**Karl Fritsch**: Observations on flower-visiting insects in Styria (1912). These observations, made in March–June and September–October in the neighbourhood of Graz and in other parts of Styria, extended to more than sixty plant species, including cultivated exotic species. It is noteworthy that the honey-bee was found to visit an ornithophilous plant, *Agave americana* L.—**Karl Przibram**: Radio-luminescence and radio-photoluminescence (3). Examination of the red fluorescence exhibited by many English fluorites after irradiation by radium reveals a band in the red without recognisable lines, this being often confined to certain positions on the crystal. Investigations with synthetic material show that red radio-photoluminescence occurs also with calcium fluoride free from rare earths. With fluorite this phenomenon is, therefore, attributed either to more frequent contamination with heavy metals and only modified by the simultaneous presence of rare earths or to the effect of the rare earths themselves, which do not then emit their characteristic lines.—**A. Dadieu**, **K. W. F. Kohlrausch**, and **A. Pongratz**: Studies on the Raman effect (19). The Raman spectrum of organic substances (isomeric paraffin derivatives). For the vibration spectrum the substituents CH_3, NH_2, and OH are mechanically

almost equivalent, so that paraffin derivatives containing only these substituents yield vibration spectra of a different type (corresponding with higher molecular symmetry) from those of analogous derivatives with the substituents SH, Cl, Br, etc.—Friedrich Lechner: Studies on the Raman effect (20). Theory of the valency force system with three mass points.

Forthcoming Events

MONDAY, July 4

Royal Institution (General Meeting at the Institution, 21 Albemarle Street, London, W.1), at 5 p.m.

FRIDAY, July 8

Physical Society of London (Special General Meeting at the Imperial College of Science and Technology, South Kensington, S.W.7), at 5 p.m.

SATURDAY, July 9

Society of Chemical Industry—South Wales Section (Special Joint Meeting with the South Wales Section of the Institute of Chemistry at the laboratories of the Cardiff Gas, Light and Coke Company, Bute Terrace, Cardiff), at 3 p.m.

Professional Codes and Business Practice

ONE of the most interesting features in the recently published report of the Medical Research Council for 1930–31 is the evidence it affords of growing relations between the medical profession and manufacturing firms. The disinclination of such professions as law and medicine to have connexion with trade is an inherited prejudice which, however natural or healthy in its origin, in modern society can be greatly to the public disadvantage. As the report points out, the greater reluctance of medical men in Great Britain as compared with their continental colleagues to undertake clinical trials of new synthetic substances of therapeutic importance in co-operation with manufacturers, and to publish the results over their own names, frequently militates against the clinical application of scientific research carried out at the universities. New substances first produced in Great Britain sometimes come into general recognition and use by way of clinical reports published in German and other foreign journals.

The problem of securing trustworthy clinical trials of new substances produced by manufacturing firms has recently been discussed by the Medical Research Council with representatives of the Association of British Chemical Manufacturers, and a Therapeutic Trials Committee has been organised under the supervision and authority of which trials of new products may be arranged. This Committee is in close touch with the Chemotherapy Committee, which may be responsible for the experimental work desirable or necessary before the drugs or preparations are used in man, and, in consultation with the Association of British Chemical Manufacturers, agreed conditions have been accepted under which the new substances may be submitted to the Therapeutic Trials Committee for clinical study.

These developments, while affording a welcome indication of the breakdown of earlier prejudices against participation in industry, are only a new phase of relations between the Medical Research Council and chemical industry which have existed for some time. The function of the Council to assist in rendering the results of scientific discovery available for the public and the medical profession frequently involves establishing close co-operation between the original scientific workers and those whose work is concerned with the developments necessary for manufacture and application of the discovery. Only by such co-operation is it often possible to minimise the delay in the elaboration of the necessary technique for economic and successful

production on a large scale. It is thus inevitable that some relations with chemical industry should exist, and the closer the co-operation the easier it is to negotiate the difficult path between the laboratory discovery and successful manufacture, and the more rapidly will the manufactured product become available for general clinical use.

This problem of development is, however, by no means peculiar to pharmaceutical preparations. It is encountered in many other fields of industry, where new and improved products are continuously being developed as a result of research. The adage that the good is enemy of the best finds perennial expression in, for example, engineering, where the manufacturer of a new and greatly improved alloy is often faced with the problem of convincing a prospective user that it is worth while paying ten per cent more for an article which is really a hundred per cent better than the original. It is undeniable that the successful application of research is largely dependent upon the user's appreciation of the value of the products which it puts at his disposal. Unless the user—who is not necessarily the ultimate public, but may be a professional man, such as a physician, or a manufacturing firm purchasing, for example, alloys for constructional purposes—is ready to adopt new products, the manufacturer finds little encouragement for his expenditure on the development of new and improved articles. The difficulty is increased because, under the present conditions of trade and industry, the mechanism of buying and selling departments is largely in the hands of those who are not trained technicians, and are unable to assess independently the merits of the new products, or to distinguish exaggerated or unreliable claims made in advertising literature.

Serious efforts are, of course, being made to overcome this difficulty in fields other than that of medicine. The Institute of Metals, for example, has endeavoured to bring into personal contact the technical as well as the business men concerned with the manufacture of materials and their application in engineering and elsewhere. Much of the propaganda literature now issued by industrial firms is highly informative and frequently contains scientific data not published elsewhere and of real value to users of the products described. Such publications are now being treated much more seriously, and deserve no longer to be confined to the offices of the buying department, but to be indexed and circulated to the technical staff in the same way as the recognised scientific journals in which much of the information may be afterwards published.

In spite of these efforts, absence of technical knowledge in the buying department may often lead to a mistaken insistence on a cheaper material when the new and possibly more expensive product would really prove far more satisfactory or economical, and at the best the wheels of progress are clogged and efforts to improve products are hampered.

Thus the experience of such diverse industries as the metal and engineering industries and the fine chemical industry indicates that much more is being demanded of scientific workers in every aspect of industry, and that progress demands the rapid disintegration of those prejudices which formerly kept professional men and industry apart. The scientific outlook and a scientific or technical training are becoming as important, if not as indispensable, in the buying and selling organisations of industry as in the control of technical operations or in research. Equally it appears that the scientific worker might make an important contribution even in the publicity or advertising side of industrial organisations, at which in the past he has been prone to look askance. It is only as he contributes both his scientific knowledge and his professional integrity and traditions to the development of advertising literature of real scientific merit that some of the obstacles to the development of new products can be most easily overcome. The development of such methods in advertising is a logical outcome of the rationalisation of industry, but its achievement requires the co-operation of scientific workers as professional men. The report of the Medical Research Council already makes it plain that such professional co-operation is imperative in the public interest if new remedies are to be tested and developed adequately, and a change in the attitude of the medical profession to advertising seems inevitable.

Fundamentally these changes or tendencies are but an indication of the impossibility of dealing with industry or society in watertight compartments, or of restricting the influence of scientific thought once scientific methods have been applied to any extent. Inevitably a scientific outlook is required in every sphere of life, and while this will only be attained when science finds its rightful place in our educational system, much depends on the contribution of the scientific worker himself. It is only as he is brought into closer and more open contact with the general public that society can understand the true meaning of scientific methods and their contribution to the common weal.

The task which thus devolves on scientific

workers is by no means simple. While safeguarding their professional codes and standards of qualification, they are called upon to participate in the general life of the community, divesting themselves of that air of mystery which hinders the proper appreciation of their work and is often regarded as a cloak for humbug and inefficiency. We cannot expect that science and its methods will exercise the influence that is so essential to-day, in all aspects of social and economic life, unless in their own professional conduct and organisations scientific men are dominated by scientific and rational principles. Habits tending to secrecy, with the encouragement which they inevitably give to quackery, must definitely be discarded; and the indications that the medical profession is more disposed to co-operate with other classes of scientific workers and to abandon older prejudices are the more welcome because conservatism and the species of mental inbreeding which it engenders are among the greatest dangers to the efficiency of professional workers, whether in science or in other fields of human endeavour.

Vitamins

The Vitamins. By Dr. Ethel Browning. (Monographs of the Pickett-Thomson Research Laboratory, Vol. 1.) Published for the Pickett-Thomson Research Laboratory. Pp. xxxii + 575 + 7 plates. (London: Baillière, Tindall and Cox; Baltimore, Md.: The Williams and Wilkins Co., 1931.) 42*s.* net.

CONFRONTED with a volume such as that recently written by Dr. Ethel Browning, a reader becomes acutely aware of the interest which the discovery of vitamins has aroused throughout the scientific world and the enormous amount of work this has elicited in the brief period of one decade. It is probably true to say that no other fundamental discovery in biological science has led to such concentrated research in so short a time.

Various kinds of books on the subject of vitamins can be imagined, but two types suggest themselves at once: one to tell the general public the entrancing story of their discovery, history, and practical importance in health; the second to set out for the teacher and laboratory worker the detailed facts of their action and to guide him in tracking down the original source of knowledge on individual points. The writer of either of these books should be possessed of the wisdom of Solomon, but in the second case he must also have a more extensive knowledge, not only of physiology, pathology, and medicine, but also of physics and chemistry, as well as a personal experience of laboratory and clinical feeding tests.

Popular books on vitamins have been published from time to time, but the majority of the writers leave the average reader with a feeling that vitamins are substances of great importance only for polar explorers and those whose diet consists of polished rice. The fact is, of course, that the discovery of these substances and their actions is leading to one of the greatest silent revolutions Great Britain has ever experienced, a revolution in health and physical welfare, which will compare in magnitude with that following the discovery of the part played by micro-organisms in disease. It is becoming more generally recognised that in some respects the nutritional condition of our population is appalling, and that an infinite amount of physical defect, pain, and ill-health results from improper feeding, especially in early life. Knowledge of the nutritional factors responsible for such widespread defects as rickets, decayed teeth and pyorrhœa, and their sequelæ is being firmly established. Instead of an ill-grown, bandy-legged, anæmic population with septic and edentulous mouths, we already know how to substitute a taller, heavier, straight-limbed race with well-grown jaws and strong, healthy teeth. A popular book on vitamins should tell the world these facts and how they can be procured. Ultimately even the politician might be moved to do something in the matter and direct his attention to the prevention rather than the cure of disease.

The second type of book, namely, that dealing in a comprehensive way with all the scientific facts at present known about vitamins, had obviously to be written if progress was not to be impeded by needless repetition, by saturation of the research mind with a mass of unco-ordinated facts, and by endless waste of individual time in exploring the literature. So early as 1919 the Medical Research Council prepared a monograph of this kind; a second edition appeared in 1924, while the third is now in the press. This book has been written by a group of experts and practical workers, for it was thought only in this way could a satisfactory standard be reached. Now we find Dr. Ethel Browning tackling the job single-handed. The least the present reviewer can do is to bow his head and express his admiration of her pluck and energy in making such an attempt. This emotion is not lessened when he sees that the book is of quarto size, contains 432 pages of text, 90 pages of references to literature, about 50 pages of index of authors and subjects, and 7 excellent plates showing

histological changes associated with vitamin deficiency or excess.

In the introduction, the author states that attention has been primarily focused during the last few years on the attempt to isolate vitamins as chemical entities. She has therefore tried to neutralise this tendency to develop the subject into a biochemical treatise by devoting as much attention as possible to the clinical and experimental aspects, for she says that "it is, after all, in the preventive and therapeutic possibilities of vitamin administration that their ultimate importance to humanity in general will consist". This object is undoubtedly to be commended, especially as much of the chemical work has been unproductive.

Part 1 of the book opens with a historical sketch of the discovery of vitamins, and this is followed by a survey of their physiological actions, together with a description of the methods for their quantitative estimation known at the time of writing. The second part discusses in detail the properties, functions, and distribution of the fat-soluble vitamins A, D, and E, while in the third part the water-soluble vitamins B and C are similarly treated. Excellent tables indicating the vitamin content of foodstuffs are given, with references to the various authors from whose publications the facts are taken.

The book is well set out and any particular aspect that the reader wishes to study can be easily traced by means of the index, and the references to the investigations mentioned can readily be found. The author not only gives references to the literature, but also she has obviously read many of the papers carefully (although in some instances she has quoted extracts from them without either knowledge or thought as to their accuracy). Further, she has attempted to give a critical historical account of the development of knowledge in many branches of the subject. This makes the book more interesting to the average reader, but it has obvious pitfalls, for those in the inner secrets of the vitamin story know only too well that the real history of many of these discoveries is familiar to few outside the actual workers themselves.

It is evident that the vastness of the subject has handicapped the writer, especially as she has aimed at the inclusion of all investigations, good, bad, and indifferent, and has mentioned each, irrespective of the weight of scientific evidence. Consequently, the value of the book to the reader with no specialised knowledge is seriously impaired, for sometimes evidence quoted in one sentence is negatived by that given in the next. Again, there are examples of quotations from work which, in the light of later advances in technique, has lost its significance, and therefore its value is negligible to all except the most specialised worker.

In many respects Dr. Browning's book is very good, and its merits are sufficient to outweigh most of the errors, but it is doubtful whether they are great enough to counterbalance the effect of the uncritical 'all-in' method of exposition adopted by the author.

The Nature of Physical Theory

The Nature of Physical Theory: a Study in Theory of Knowledge. By Prof. Victor F. Lenzen. Pp. xii + 301. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1931.) 21*s*. net.

"IT is the purpose of this book to analyse the concepts, principles and systems of physical theory." There are many books with that purpose appearing to-day; a feature common to most of them is a lack of reference to any of the others. In this respect Prof. Lenzen's book is no exception; some of the most prolific writers, such as Dingler, Jeffreys, and (perhaps I may add) Campbell, are not mentioned at all; most of the references to the others are merely incidental and give no idea of their main conclusions.

Several explanations suggest themselves. One, doubtless supported by those who still regard any attempt to go behind the imitative orthodoxy of our textbooks as scientifically immoral, is that all such inquiries are inevitably barren, and that no one does or can say anything on such subjects worth the attention of others. Another is that those who are concerned with principles are naturally impatient of conventions, and that writers in this group are reacting—perhaps reacting too far—from the exaggerated importance that is attached in technical writings to giving chapter and verse for every statement, however obvious, that anyone has ever made before. A third is that the subject is so vast that no writer can possibly cover the whole of it, that all treatments of it are necessarily eclectic, and that so far no writer has needed to refer to the work of any other, because he has always been dealing with an untouched part of the field. Prof. Lenzen would obviously reject the first explanation; he would probably admit that the second is partially true, and that many of his ideas, though not formally 'acknowledged', are not original; but the third he would regard, I think, as going to the root of the matter. Others writers, he would

say, though their works may be learned and profound, have not answered the particular questions in which he is interested.

If this is the reason why he has neglected previous work almost completely, it becomes very important to know precisely what are the questions he is trying to answer. After the sentence already quoted, he continues: "The procedure will be to build up physical theory from the aspects of the physical order given in sensation". That suggests that the relation between physical theory and the experiments on which it is based is to be his main theme. As a matter of fact, it is avoided so completely that the problems connected with the terms *induction*, *probability*, *experimental error* are not even mentioned; none of these terms, nor any equivalents for them, appear in the index. Other passages in the introduction suggest that Prof. Lenzen takes the typically philosophical view that physical theory consists of a set of definite propositions, the origin of which is not important, and that his problem is to exhibit them as a systematic whole, free from logical contradiction. But then it is surprising to find him so little concerned with the classical paradoxes, such as those of statistical mechanics; he does not seem to realise that there is any difficulty in the conception of *molekular ungeordnet*. Nor does he actually show himself indifferent to origins. If "the data of experimental physics consist of space-time coincidences", what relevance other than historical can the "sensation of hotness and coldness" have for the concept of temperature? And if history is Prof. Lenzen's concern, what are we to make of his statement that *space*, of which Archimedes knew nothing and Newton very little, is one of the fundamental concepts of physics?

An uncomfortable suspicion is thus generated that Prof. Lenzen has no definite aim, and that his sturdy independence arises from ignorance of what others have said. It is inevitably confirmed by his treatment of subjects, such as measurement, on which much has been said; for it is difficult to find any other reason why he should simply ignore distinctions on which others have insisted. I hope that I am wrong and that others will find a unity and a profundity in Prof. Lenzen's work which I have missed; but as it is, I am debarred from performing adequately even the first duty of a reviewer, namely, to describe clearly what the book is about. Let me end, therefore, by simply giving a list of the chapter headings, from which readers may judge for themselves: General Character of Physical Theory. I.—Special Classical Theories, (i) Fundamental Concepts and Methods, (ii) Euclidean Geometry, (iii) The Theory of Time, (iv) Kinematics, (v) Dynamics, (vi) Electrodynamics, (vii) Thermodynamics. II.—Unitary Systems of Physical Theory, (viii) The Mechanical, Electrodynamic and Geometrical Conceptions of Nature (viii, ix and x, xi and xii). III.—Quantum Theory, (xiii) The Classical Quantum Theory, (xiv) Symbolic Quantum Mechanics. IV.—Methodological Principles, (xv) The Concept of Substance, (xvi) The Concept of Causality.

NORMAN R. CAMPBELL.

Science and Poetry

(1) *The Captive Shrew: and other Poems of a Biologist.* By Julian S. Huxley. Pp. xii+101. (Oxford: Basil Blackwell, 1932.) 5*s.* net.

(2) *Lyra Modulata.* By Sir Ronald Ross. Pp. 21. (London: Harrison and Sons, Ltd., 1931.) 10*s.* 6*d.*

(3) *In Exile.* By Sir Ronald Ross. Third edition. Pp. xii + 80. (London: Harrison and Sons, Ltd., 1931.) 10*s.* 6*d.*

THE prediction of Wordsworth a hundred years ago seems to be coming true. There is more and more fine verse directly and avowedly inspired by science. We have noticed in these columns more than once the trilogy of Mr. Alfred Noyes on the growth of science, the "Torch Bearers" in their triple aspect towards the heavens, the earth, and suffering man. The works now before us by Sir Ronald Ross and Prof. Julian Huxley have the added and special interest of being poems by men of science themselves. They are alike in this and in being good: all of them are well worth printing and many of them deserve to live. But in other respects the two poets are in marked contrast.

(1) Julian Huxley's little book brims over with merry thoughts and delight and questioning about all the sights in Nature which he remembers from boyhood up. Mountains, trees, birds—especially birds—and all sorts of light-effects in sun and moon; the poems, short as they are, are full of such touches and it is tempting to quote. Then in the later ones come half-serious, half-laughing comments on the universe of Jeans and the self of Freud. It is a delightful book, the fruit of a lively receptive mind, with reminiscences of Walt Whitman in its *vers libres* and of Browning in its ingenious rhymes.

(2 and 3) Sir Ronald Ross is extraordinarily different in style and temper; yet, as another man of science, alike in the questioning spirit displayed so strongly in his life-work and in the thoughts on

man's place in the universe with which the volume ends. The volume called "In Exile" contains verses written during his work in India in the 'nineties on malaria. They are now reprinted in a third edition with a preface in which Sir Ronald comments on the strange neglect with which the earlier issues were received. He is fully justified in his consciousness of their unique interest, deeply moving utterances wrung from the soul of a man in grips with one of the most terrible scourges of the human race. He is longing all the time for the sympathy and refreshing vigour of his native land, and weighed down by the horrors of the pitiless climate and the poverty and suffering of those around him. He is steadily approaching by patient and unrelaxing efforts the solution of one of the great evils which oppress his fellows. The poems have therefore a permanent and intense significance. They are hammered out with the utmost care, and will undoubtedly retain their value both as poetry and as the record of one of the most decisive applications of science to the alleviation of human suffering.

One must regret that the format and the price at which both Sir Ronald's volumes are produced will still confine their appreciation to a small circle of readers. Sir Ronald, akin in this to the late Poet Laureate, is keenly interested in the technique of verse and offers several experiments in the smaller and later book. Of all the poems included, that called a 'Pæan', which concludes the earlier book, best expresses in restrained and pregnant words the spirit of man's upward march. It has something of Shelley's triumphant ode, but ends on a note of greater wistfulness and need of effort. F. S. M.

Sugar Cane Entomology

Handbook of the Insects and other Invertebrates of Hawaiian Sugar Cane Fields. Compiled by Francis X. Williams. Pp. 400. (Honolulu, Hawaii: Hawaiian Sugar Planters' Association, 1931.)

THIS volume is a handbook dealing with the creatures inhabiting the Hawaiian sugar plantations—it is, in fact, a guide to the invertebrate fauna of the fields. It treats not only of species that are definitely injurious in one way or another, but also of those that are beneficial either in the rôle of parasites or of predators. At the same time, species that are more or less neutral, in their relations with the cane crop, also come in for consideration. In a few words, it enables any creature found in the cane fields to be identified, its biological status to be ascertained, and also whether it is indigenous to the islands or accidentally, or intentionally, imported. Insects naturally occupy the major portion of the book, but there are also included sections dealing with Myriapoda, Arachnida, Isopoda, Mollusca, and Nematoda. Of these several minor sections, that concerned with nematodes is of special importance.

The members of the entomological staff of the Sugar Planters' Experiment Station at Honolulu have built up for themselves a high reputation. Some of the best-known names are those of Englishmen. Their achievements in the domain of biological methods of pest control are unique and are the envy of the rest of the world. It is not too much to say that their achievements resulted in the saving of the whole archipelago from utter ruin of the cane-growing industry.

The policy of the governing body of the Honolulu Station is one that might be emulated with advantage elsewhere. This policy has been based upon the fullest application of scientific principles to the cultivation and protection of the sugar cane. The governing body has selected its staff from among men of real scientific calibre and has given these men constant moral and financial support. We see the reward of a consistent scientific policy in the comparative freedom from serious insect pests enjoyed by the Hawaiian cane fields to-day. This result has not been achieved through the perpetual spraying and dusting of crops with toxic compounds—it has come about through the judicious introduction of the right kinds of parasites and predators from other lands, coupled with a vigilant quarantine system. Let us hope that the same sound principles that have guided the Station's policy in the past will be rigidly pursued without relaxation. Increased facility for communication with the rest of the world affords increased chances for noxious immigrants to be carried to the islands. To preclude their obtaining a foothold in so congenial a climate demands constant watchfulness. Happily, both the quarantine service and the specialists at the Planters' Experiment Station work harmoniously towards this same object.

In his introduction to this volume, the late Dr. F. Muir sets out the guiding principles that have led to the remarkable success of biological control in the Hawaiian Islands. Dr. Muir's practical experience in this domain is perhaps unequalled, and his remarks in consequence are authoritative. The rest of the book is written by Dr. F. Williams, well known for his researches on the aculeate

Hymenoptera and other groups. In carrying out this task he has brought together the work of many investigators over a diverse field. Much of the original information is based on researches the results of which have appeared in bulletins and other publications seldom found in libraries in Europe. It is therefore gratifying to find much of this work thus brought together in a convenient compass and shown in its true perspective, accompanied by the original high-class illustrations. At the end of the book there is a very complete bibliography and an adequate index. A. D. IMMS.

Short Reviews

Handbuch der Klimatologie. Herausgegeben von W. Köppen und R. Geiger. In 5 Bänden. Band 1, Teil A: *Mathematische Klimalehre und astronomische Theorie der Klimaschwankungen.* Von Prof. M. Milankovitch. Pp. iv + A176. 27 gold marks. Band 1, Teil D: *Mikroklima und Pflanzenklima.* Von Dr. Rudolf Geiger. Pp. iii + D46. 9 gold marks. Band 1, Teil E: *Einfluss des Klimas auf den Menschen.* i. *Medizinische Klimatologie,* von Dr. W. Borchardt; ii. *Klima und Kultur,* von Prof. Dr. K. Wegener und Prof. Dr. W. Köppen. Pp. iii + E80. 11·70 gold marks. Band 1, Teil F: *Klimatologie der freien Atmosphäre.* Von Prof. Dr. A. Wagner. Pp. iii + F70. 12·60 gold marks. Band 4, Teil R: *Klimakunde von Hinterindien und Insulinde.* Von Dr. C. Braak. Pp. iv + 125. 31·20 gold marks. (Berlin: Gebrüder Borntraeger, 1930–1931.)

SINCE the last (third) edition of Hann's "Climatology" appeared in 1908–11, the observed data have enormously increased for nearly all parts of the earth. The need for a critical comparative compilation of this mass of facts is evident, and Profs. Köppen and Geiger have therefore planned a large handbook of climatology, dealing with the whole subject, including many more meteorological elements than were tabulated by Hann. The complete work will be more than twice as large as Hann's last edition. Naturally it is to be a co-operative work, and although the main language used in it is German, several British and American authors, dealing with parts of the British Empire and North America, will write in English. It is hoped that the whole handbook will be published in 1934. It will occupy five volumes, each comprising several parts appearing separately; the quoted prices for these parts are for separate sales, there being a reduction of one-third if the whole handbook is ordered; even so, the prices seem high, particularly for the part last issued (vol. 4, part R, costing more than 20 gold marks, reduced price, for less than 130 pages, in paper covers). At present, four parts of volume 1, and one of volumes 2, 4, are issued.

An unfortunate feature of this piecemeal production is that most of the parts, which in some cases are of considerable length, have no alphabetical authors' or subject index; these are apparently reserved for the completion of the whole handbook, since the concluding part (F) of volume 1 (of which two parts are still missing) has no index. The first volume deals with general climatological questions, and the remaining four with regional climatology. Part A of volume 1 is largely devoted to a lengthy exposition by Prof. Milankovitch of the radiative equilibrium of the atmosphere, and of his astronomical theory of the ice ages (a much-disputed topic), and contains no mention of Simpson's important work on these subjects. S. C.

Some East African Coniferæ and Leguminosæ. By Dr. L. Chalk, Dr. J. Burtt Davy and H. E. Desch. (Forest Trees and Timbers of the British Empire, 1.) Pp. 68 + 10 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1932.) 5*s.* net.

THIS is the first of a series dealing with the forest trees and timbers of the British Empire, edited by Dr. L. Chalk and Dr. J. Burtt Davy, of the Imperial Forestry Institute, Oxford. The series will supply a want which has long been felt, a lack of correlation between our knowledge of the systematy of the tree and the anatomical structure of the wood, in the forestry of various parts of the British Empire. In his preface to this brochure, Prof. R. S. Troup, director of the Institute, remarks that no one has yet perfected an ideal form of description of wood anatomy. The subject is complicated by differences obtaining in different parts of the section, and by the considerable range in the dimensions of individual elements even at the same point in a tree; but with the development of a uniform system it should be possible approximately to determine a species from adequate material of the timber.

The present publication deals with some important east tropical African timber trees, *Juniperus procera* and *Podocarpus gracilior* and *milanjianus*, which form the cedar forests especially on Mt. Kenya, and *Widdringtonia Whytei*, the Milanje cypress, which with *Podocarpus milanjianus* characterises the forests of Mt. Milanje in Nyasaland. Descriptions are also given of ten species belonging to the family Leguminosæ of greater or less importance commercially. Good botanical descriptions of the species are included, with notes on distribution, climatic conditions, etc., but the most valuable feature is the detailed description of wood structure. The illustrations showing habit of the tree, anatomical structure, leaf and floral characters, are a helpful feature, and the introduction of keys to the African species of the various genera will be welcomed by the working botanist or forester. Incidentally, we commend the decision of the authors to regard the East African *Widdringtonia* as generically distinct from the Australian *Callitris* and the North African *Tetraclinis*.

The success of the task undertaken by the editors—the systematic description of the trees and woods of the Empire—will depend largely on a supply of reliable material and on the collaboration of workers with local experience in various parts of the Empire. A. B. R.

The Book of Amber. By Dr. George C. Williamson. Pp. 268 + 5 plates. (London: Ernest Benn, Ltd., 1932.) 15*s.* net.

MR. HERON-ALLEN's catholicity of interests includes the study of some aspects of amber; and he therefore very appropriately contributes a foreword to Dr. Williamson's most admirable book upon the origin, history, characters, distribution, and uses of this remarkable fossil resin from pines and other trees. It is, indeed, strange that, with the exception of some rare booklets and scattered papers or incidental chapters in other works, no general monograph of this kind, bringing together everything of interest concerning amber, has been published. Dr. Williamson writes with expert knowledge of his subject, and has devoted his leisure time over a period of twelve years to the compilation of his book. We join with Mr. Heron-Allen in a "tribute of admiration" at the result.

Among the subjects surveyed are classical allusions to amber; prehistoric amber routes in Europe; remains of plants, insects, and other creatures enclosed in amber; folklore, and medical uses; mineralogical characteristics; types, the chief of which are represented in a beautiful coloured frontispiece; tests; and pressed amber. The bibliography near the end of the book shows that Dr. Williamson is familiar with practically every work or paper relating directly or indirectly to amber. It may be of interest to recall in this connexion that Mr. Minakata described in NATURE of Jan. 24, 1895, Chinese theories of the origin of amber, including the resin of pines, and that Mr. Murray Stuart gave reasons in the issue of Jan. 20, 1923, for believing that some specimens of pale Chinese amber represented fossilised dammar—a resinous substance produced by certain bees.

Recent Advances in Materia Medica: being a Description of the Methods of Preparing and Testing Sera and Vaccines, Hormones and Vitamins, with an Account of their Properties and Medicinal Uses. By Dr. J. H. Burn. (The Recent Advances Series.) Pp. x + 224. (London: J. and A. Churchill, 1932.) 12*s.* 6*d.*

IN this volume of the "Recent Advances" Series, the author has confined himself to a consideration of some of those substances of value in therapeutics which are obtained from animal sources or require the use of animal tests of toxicity and potency before issue. The work is intended chiefly for students of pharmacy, and therefore includes certain elementary physiological details. It covers a field, however, of increasing importance; and its pages make available in small compass much information which ordinarily could only be obtained by a search of the original literature or a larger book dealing with biological assays. For this reason it can be recommended to physiologists and pharmacologists, as well as to medical practitioners who may wish to have some knowledge of the methods of preparation and test of biological products. The specialist may also find it useful for information on the subject of the biological assay of substances with which he may have had no recent experience.

The earlier chapters deal with antitoxins, sera, and vaccines; the middle section is devoted to the hormones, liver extract, and the arsenobenzene group of compounds; in the final chapters the uses and tests of the vitamins are considered. In the last two chapters the application of the results of biological tests to human beings and the principles of biological methods are discussed. The volume gives a readable account of a subject which is related to many branches of medical science, and therefore likely to be neglected except by the specialist.

The Statesman's Year-Book: Statistical and Historical Annual of the States of the World for the Year 1932. Edited by Dr. M. Epstein. Sixty-ninth Annual Publication, revised after Official Returns. Pp. xxxiv + 1474. (London: Macmillan and Co., Ltd., 1932.) 20*s.* net.

THIS valuable volume with its mass of carefully revised statistical information appears with its usual regularity. The arrangement follows that of previous years, and the size of the book is essentially the same. No new States have made their appearance, though the cession of Manchuria occurred in time to be noted among the addenda. New population figures are given for Great Britain, Canada, France, Italy, and many other States the census of which fell in the year under review. In order to indicate more clearly the trend of trade of Great Britain with other countries, re-export figures have been added to the tables summarising the trade of each country. The usual introductory tables are given of world production of petroleum, coal, iron and steel, gold, etc. The two coloured maps show respectively the railways of Manchuria (now Manchow-kuo) and the Zuider Zee reclamation. In the latter, the completion of the North-west Polder marks the success of the first step in the scheme. The lists of books, official and non-official, given for each State are one of the most useful features of this reference volume.

Electrical Machinery and Apparatus Manufacture: a Complete Work by Practical Specialists describing Modern Practice in the Construction and Manufacture of Apparatus and Machinery. Edited by Philip Kemp. In several volumes, by various authors. (London: Sir Isaac Pitman and Sons, Ltd., 1931–32.) 6*s.* net each vol.

THESE volumes are nicely bound, of convenient size, and are clearly printed. They are not intended to replace existing textbooks, dictionaries, or encyclopædias. They may prove useful to experts in particular branches of electricity who desire to supplement their knowledge of the actual construction and manufacture of electrical machinery and apparatus. We liked the section on works organisation and administration by A. P. M. Fleming. The section also on accumulator construction and manufacture contains practical information not easily found elsewhere. The descriptions given range from heavy machinery down to the manufacture of thermionic valves.

Prof. Planck and the Principle of Causality in Physics*

By Dr. Allan Ferguson

THE Guthrie lecturers before the Physical Society have in the past covered a wide range of knowledge in physical science, but they have very definitely concerned themselves with concrete problems. Atomic nuclei, electrodeless discharges, the properties of the elements under high pressures, the scattering of X-rays in gases, positive rays —these are typical of the subjects which have been discussed and illuminated by distinguished lecturers in past years. It has been left to Prof. Max Planck to treat with wide scholarship and philosophic insight one of the most difficult of the problems known to the thought of any age—that of the meaning and validity of the concept of causality.

It was a singularly happy chance which dictated the choice of this topic to Prof. Planck, for he, as much as any other living thinker, has forced upon the minds of the rank and file of physicists the necessity for some measure, at least, of metaphysical knowledge, and has roused us from that attitude of crude realism typified by Johnson, who, required by the insatiably curious Boswell (on Harwich beach, of all places) to criticise Berkeley's idealism, "answered, striking his foot with mighty force against a large stone till he rebounded from it, 'I refute it *thus*'". Nor must it be imagined that this simple attitude was a prerogative of the privates in our army. The habit of mind was to be found in very high places. Thus, turning to a lecture on the wave theory of light by the late Lord Kelvin, we find therein the very definite and uncompromising statement: "You can imagine particles of something, the thing whose motion constitutes light. This thing we call the luminiferous ether. That is the only substance we are confident of in dynamics. One thing we are sure of, and that is the reality and substantiality of the luminiferous ether." Less than fifty years have passed since these words were spoken, less than twenty-five since the speaker died; and the onset of the revolutionary change which has come over our physical thinking is marked by a paper published during Lord Kelvin's lifetime under the name of Max Planck in the last year of the nineteenth century.

It is impossible, and undesirable in the scope of a short article, to attempt an exhaustive review of the development of the concept of causality, but it is not without interest and bearing on present-day thought to consider briefly the development of the concept since the age of Newton. Locke, Newton's elder contemporary, states a clear and simple view, which, however, scarcely touches the fringe of the problem, when he says: "Thus, finding that in that substance which we call *wax*, fluidity, which is a simple idea that was not in it before, is constantly produced by the application of a certain degree of heat, we call the simple idea of heat in relation to fluidity in wax the *cause* of it, and *fluidity* the effect. . . . So that whatever is considered by us to conduce or operate to the producing any particular simple idea, whether substance or mode, which did not before exist, hath thereby in our minds the relation of a cause and so is dominated by us." The notion of *power* in this definition of cause is particularly evident.

The mind of Newton, as Prof. Brodetsky has recently remarked, was dominated by the principle of causality, and he was ever searching for a physical picture which should represent the results of his investigations. This is very true; but it is to be remembered that in this, as in so many other matters, Newton displayed a philosophic breadth of view which was well in advance of the doctrines of his day. He makes, for example, a physical picture of matter as formed in "solid, massy, hard, impenetrable, moveable particles", and assumes that they have not only a *vis inertiae*, but are moved by certain active principles, such as gravity. These principles are to be considered "not as occult qualities . . . but as general Laws of Nature . . . their Truth appearing to us by Phænomena. . . . To tell us that every Species of Things is endowed with an occult specifick Quality by which it acts and produces manifest effects, is to tell us nothing; but to derive two or three Principles of Motion from Phænomena and afterwards to tell us how the Properties and Actions of all corporeal Things follow from these manifest Principles would be a very great step in Philosophy, though the Causes of those Principles were not yet discovered; and therefore I scruple not to propose the Principles of Motion above mentioned, they being of very general extent, and leave their Causes to be found out." Evidently despite, or perhaps it would be better to say, along with his physical picture, Newton takes the view that we have made an important step when we have subsumed a number of perceptual facts under one general formula.

Although he may be indebted to Glanvill and other earlier writers, it is to Hume that we owe the first clearly ordered statement of the experientialist doctrine of causation. Such a generalisation, applied to a falling body, as "the earth attracts the stone", is explained as a generalisation from thousands of such observations. "Adam . . . could not have inferred from the fluidity and transparency of water that it would suffocate him, or from the light and warmth of fire that it would consume him. No object ever discovers by the qualities which appear to the senses, either the causes which produced it or the effects which will arise from it; nor can our reason, unassisted by experience, ever draw any inference concerning real existence and matter of fact." So, basing his argument entirely on experience, Hume defines a cause as "an object, followed by another, and

* Seventeenth Guthrie Lecture before the Physical Society, delivered by Prof. Max Planck on June 17.

where all the objects similar to the first are followed by objects similar to the second. Or, in other words; where, if the first object had not been, the second had never existed."

We may note here that the experientialist position was, in the nineteenth century, further developed by Mill, who states that the law of causation "is but the familiar truth that invariability of succession is found by observation to obtain between every fact in nature and some other fact which has preceded it, independently of all considerations respecting the ultimate mode of production of phenomena, and of every other question regarding the nature of things in themselves". Mill, moreover, meets the objection urged by Reid that on such a doctrine of succession, day must be the cause of night and vice versa, by pointing out that invariable sequence does not necessarily involve the notion of causation. To involve this last-named notion, the sequence must be *unconditional* as well as *invariable*. The day-night sequence obviously does not conform to this test, inasmuch as it is conditioned by the behaviour of our luminary, the sun. "We may define, therefore, the cause of a phenomenon to be the antecedent, or the concurrence of antecedents on which it is invariably and unconditionally consequent."

Kant's discussion of causality, wherein he takes the position that we could never make such a generalisation as "the earth attracts the stone" unless we had knowledge *a priori* and independent of experience that each event in our perceptions has its cause, has great importance in the history of philosophic thought: here we may pass it without comment, inasmuch as Kant's views have not played any decisive part in the development of scientific theory in this or in the last century.

Nineteenth century science, indeed, and specially nineteenth century English science, was in many ways, naïvely realistic; models played a large part in its development, and, while a model may serve a very useful end if it is thrown on one side, as Maxwell discarded his models, when it has fulfilled its purpose, there are, as we have already seen, serious dangers ahead when the model is elevated to the dignity of a 'reality'. None the less, a movement was on foot, owing much to Mach in Germany, and to Pearson in England, which, had its followers been greater in number, would have eased the path of many a physicist who, harassed by the conflicting claims of determinists and indeterminists, exclaims, "A plague on all your houses—let us go and make experiments". Kirchhoff had the root of the matter when he wrote, "Die Mechanik ist die Wissenschaft von der Bewegung; als ihre Aufgabe bezeichnen wir: die in der Natur vor sich gehenden Bewegung *vollständig* und *auf die einfachste Weise* zu beschreiben".

We live in a world of perceptions; sense impressions come and go; and we find that we can regularise these impressions if we devise a *conceptual* world of atoms and molecules, from which we build up particles and molar masses the behaviour of which corresponds to the routine of our sense impressions. Given a frame of reference, we can formulate laws of motion for two isolated particles in a conceptual world, which may be summed up in the statement that whatever the relative positions of the particles, the *ratio* of their accelerations is always found to be constant; we define this ratio as the inverse mass-ratio of the particles; and since in virtue of this we have the relation that

$$\text{mass of } A \times \text{acceleration of } A = \text{mass of } B \times \text{acceleration of } B,$$

we agree to give the name *force* to this product and obtain the law that action and reaction are equal and opposite. Moreover, on the basis of such definitions, we can build up a structure of bodies in the conceptual world the motions of which, predictable under the descriptive laws formulated, will agree with the routine of our world of perceptions. We have, in fact, *explained* certain phenomena.

Obviously, such a scheme of explanation puts out of court at once all those arguments concerning the contrast between dead mechanisms and living wills so dear to the Victorian controversialist. It is purely a matter of the relative complexity of the descriptive laws; one set of astronomical perceptions are subsumed under laws of comparative simplicity; another set of perceptions in the realm of biology requires a more complex scheme for its description. It may or may not be that in the future the two sets of perceptions may be described in terms of a common formula, but the difference, as Prof. Pearson says, is rather "quantitative than qualitative; the descriptions of mechanics are simpler and more general than those of biology". Evidently in such a description the idea of cause as involving power is out of place, and the definition in terms of invariable (and unconditional) succession as developed by Mill is also here appropriate.

Such, then, were the views concerning causality and scientific explanation which had been developed when the twentieth century and the quantum theory came into being. How have they been modified by the discoveries of the last generation?

This is the question which Prof. Planck sets out to answer, and, alive to the fact that most controversies, in the absence of exact definitions, tend to degenerate into logomachies, he seeks for an exact definition of the causal condition and finds it in the statement that *an event is causally conditioned if it can be predicted with certainty*. Prof. Planck goes on to remark that this statement has to be taken to mean that the possibility of making a correct prediction forms an infallible criterion for the agency of a causal connexion, but not that the two mean one and the same thing. In daytime, he remarks, we can predict with certainty the advent of night; but day is not the cause of night.

Prof. Planck then points out that, nevertheless, we assume a causal connexion in cases, for example, weather forecasting, where a correct prediction may not be possible, though in a case such as the last named the unreliability may be determined by the complicated nature of the object considered. In this part of his address, the compression of the

thought has led to obscurity which may give rise to misinterpretation. Any event which may be predicted with certainty is in the universe of causally conditioned events. This latter universe, we note, may be coterminous with or greater than that of predictable events. If we interpret Prof. Planck rightly, the statement has to be taken at its face value and gives no indication of the *sequence* of conditioned events—no indication, that is, of the *two* events which stand to each other in the relation of cause and effect. Thus, *day* is an event which may be correctly predicted in the night-time; all that we assert, then, is that day is a causally conditioned event, not that there is, or is not, any causal connexion between day and night. This definition, in its condensed form, is so different from those advanced by other philosophers, who are concerned, in a definition of cause and effect, with an invariable *sequence* of events, that it should be carefully examined in the light of the arguments of Hume ("Enquiry concerning Human Understanding", Section vii.) and of Mill ("Logic", Book iii. Chap. v.).

Taking the phrase as it stands, we find that, in the realm of quantitative physical events, however simple the event, however delicate our instruments, we cannot calculate *accurately* in advance the result of our measurement—that is, in no single instance can we predict infallibly a physical event. Hence the dilemma—if we adhere to our definition of causality—there is *no* physical event which is causally conditioned, and we become indeterminists, asserting that not one of the laws of Nature is absolutely valid, not even the law of gravitation; the appearance of validity is illusory, and the laws are laws of probability. If, rejecting this indeterminist picture, we endeavour to retain the concept of causality, we find it necessary to introduce some modification into our fundamental definition of causally conditioned events; and that modification is made by transferring the definition to a conceptual world in which exact measurements may be made and events correctly predicted. The mechanism of this conceptual world, and the process of connecting two events in the world of perception by the use of the conceptual picture, fully agree with that previously outlined, and it would seem that the adoption of the theories of Mach and of Pearson would enable us, even while recognising that an unavoidable uncertainty is attendant on the prediction of an event in the perceptual world, to retain the concepts of causality as accurately valid in our conceptual picture, the relation between perceptual and conceptual events being subject to a slight inaccuracy in the process of translation from the conceptual world to the world of sense impressions.

More than this; in the region of gas-kinetic theory—a domain which, more than any other, might be regarded as a happy hunting ground for the indeterminist seeking a description based entirely, even down to the collisions of individual molecules, on statistical laws—the principle of causality won one of its greatest triumphs: for it has been found possible to build up in the conceptual world a strictly causal mechanism, the conclusions drawn therefrom, on transference to the world of sense impression, giving a remarkably accurate picture even of those irregular fluctuations which are the chief hope of the indeterminists.

How is this state of affairs modified by the introduction into our concepts of the quantum of action and of Heisenberg's uncertainty principle, which states that the product of the uncertainties of, for example, the position and momentum of a particle is constant, so that any gain in accuracy of the one determination is balanced by a corresponding loss in accuracy of the other? Here again a new conceptual world of quantum physics may be framed in which a strict determinism reigns, and the problem of transfer between this world and the world of sense impressions is philosophically identical with that of our classical problem. In actual fact, it is more difficult; for the symbols of our classical conceptual world bore some resemblance to the routine of our perceptions—our mechanism of billiard ball atoms and the like was based on our everyday sense impressions. The wave function is not so easily interpreted in terms of the world of sense. It does not refer to ordinary space; it does not give the values of the co-ordinates as functions of the time, but gives the probability that the co-ordinates will possess given values at a definite time—a position which gives an obvious loophole for the indeterminist.

So we find a continual sway between determinism and indeterminism. For the indeterminist the statement that the wave function is a probability function is sufficient and satisfactory; laws such as the law of gravitation present to him unsolved problems to which he must find exceptions, calculating the probability that the force will diverge from the inverse square law by a certain definite amount. For the determinist, the inverse square law is a law of Nature, and he puts up with the probability function only as a *pis aller*, to be resolved later into relations subject to law.

Prof. Planck's test of the relative value of the two positions is a pragmatic one—there is nothing for it, he says, but to adopt one of the two points of view and to see whether we obtain valuable or useless results. At the moment, in his opinion, the indeterminists are in the majority, but, while he holds the balance with remarkable fairness, it is not too much to say that his sympathies are with the advocates of causality. Nowhere does he show this sympathy more deeply than in a daring final speculation. After reverting to the fundamental propositions that an event is causally conditioned if it can be infallibly predicted and that in no single case is it possible to predict an event accurately, he points out that we retained the principle of causality by modifying the *event*—by referring this to a conceptual world.

Since, however, all predictions imply a predicter—since the certainty of a prediction depends in a high degree on that predicter—suppose we modify the subject of prediction, the predicting mind, and assume an ideal mind capable of apprehending in their minutest details all the physical occurrences of the

universe: we have here a 'conceptual' mind which would predict accurately all physical events. What the good Bishop Berkeley would think of this, we do not presume to say; the speculation is fascinating, even though, as Prof. Planck remarks, in order to accomplish such a notion we must subject ourselves to a severe restriction—we must forgo making the ideal mind the subject of a scientific investigation.

Although Prof. Planck's conviction, that the law of causality is, in spite of the difficulty of a general proof or disproof, a valuable sign-post to guide us through the tangle of perceptions in which we live, shows the direction of his own sympathies, he does not suggest that the answer he had given to the question originally raised is more than a tentative one. But, tentative though the answer may be, the question has provoked a brilliant, thoughtful, and stimulating address, which will live long in the memories of those whose privilege it was to be present at the Guthrie Lecture for 1932.

Jérôme de Lalande, 1732–1807

THE absorbing interest felt by the general reader in the outstanding men and events of the French Revolutionary period is to a great extent experienced by the student of the lives and characters of the French men of science who laboured during that remarkable time. During the latter part of the eighteenth century Paris was the centre of amazing intellectual activities, which even the vicissitudes of the most perilous days could not quench, and which, after the worst dangers were past, were resumed with increased zest. Especially was this the case with scientific studies and instruction. Old institutions of which the very life had been threatened were reorganised, and beside them sprang into existence others destined quickly to rival in renown any that had gone before. To one or other of the many institutions belonged most of the eminent men of science of France, among whom were Laplace, Lagrange, Delambre, Monge, Haüy, Berthollet, Chaptal, Coulomb, Lacépède, Lamarck, and last but not least, the astronomer Lalande, the bicentenary of whose birth occurs this month.

Joseph Jérôme Lefrançais de Lalande was born at Bourg-en-Bresse in the department of Ain, on July 11, 1732, and died in Paris on April 4, 1807, in his seventy-fifth year. Never in need of labouring for his daily bread, his life was yet one of unceasing effort, and from the time when as a boy he came under the Jesuit schoolmasters at Lyons until old age came upon him, his industry was remarkable. It is true that as an astronomer he has never been reckoned in the first rank as a discoverer or an investigator, but as an exponent of astronomy and a populariser of science he has had few equals. His industry is attested by the list of more than two hundred memoirs and books he wrote, but much of his influence on the progress of astronomy was due to the lectures he gave during the forty-six years he held the chair of astronomy at the Collège de France and to his encouragement of students. Though no great discovery stands to his credit, by his writings and lectures he gained for his favourite science a popularity previously unknown, and it is for that he is chiefly remembered.

Lalande's interest in astronomy is said to have been aroused by seeing a comet and watching an eclipse, and to have been further stimulated by reading Fontenelle's "Plurality of Worlds". It was, however, his contact with Delisle and Lemonnier which led him to abandon the law courts for the observatory, and it was through Lemonnier that as a youth of nineteen years of age he was sent to Berlin to make observations simultaneously with those being made at the Cape by Lacaille for determining the parallax of the moon. From the court of Frederick the Great and the society of Euler, Lalande returned to Paris and at the age of twenty-one was given a place as 'adjoint-astronome' in the Paris Academy of Science. He became an 'associé' in 1758 and a 'pensionnaire' in 1772.

With the account of his work at Berlin began the long series of memoirs referred to. A few years later, for Clairaut he made a mass of calculations in connexion with the predicted return of Halley's comet; in 1761 he succeeded Maraldi as editor of the "Connaissance des Temps"; in 1762 he succeeded to Delisle's chair at the Collège de France, and in 1764 he published the first part of his "Traité d'astronomie". Other parts followed in 1771 and 1792. "This compilation", wrote Thomas Young, "far excelled in utility all former works of the kind, and will always be considered as exhibiting the most perfect picture of the science such as it existed from 1760 to 1790 with all the details of practice and computation." Lemonnier called Lalande's work "the great newspaper of astronomy". Another notable work of Lalande was his "Histoire céleste", published in 1801, giving the places of 47,390 stars, the observations for which were made chiefly by his nephew Michel Lalande and D'Agelet, both of whom he had instructed.

The character of Lalande was no less interesting than his work. It was once said of him that he was as anxious to direct attention to himself as an individual as to astronomy as a science. His love of flattery and publicity was undeniable; but he possessed many admirable traits. Generous to a fault, he encouraged and provided for many young and needy students, and during the Revolution his courage led him to protect others at his own risk. He visited England in 1788, conversed with George III., crawled through Herschel's great telescope at Slough, and it was due to him that Herschel's newly discovered planet, Uranus, was for a time called after its famous discoverer. Living abstemiously himself, he placed his fortune at the disposal of others, and towards the end of his life founded the Lalande medal, which became the 'blue ribbon' of the astronomical world. Quite early in his career, in 1763, he was made a foreign member of the Royal Society, while the esteem in which his memory is still held in France was shown by the inauguration in 1909 of a monument to him at his birthplace, Bourg-en-Bresse.

New Buildings for the University of London

FRIENDS of university education throughout the world will welcome the announcement contained in an official publication of the University of London entitled, "New Buildings on the Bloomsbury Site" (pp. 18, illustrations and map), that the architect, Mr. Charles Holden, selected and appointed by the Court of the University, has completed a model of the proposed University buildings. We reproduce a photograph of the model (Fig. 1), kindly supplied by the University, and of the air photograph of the site (Fig. 2), which forms the frontispiece of T. Ll. Humberstone's "University Reform in London" (Allen and Unwin, 1926). The pamphlet is designed to give "a short account of the work of the University, of its present location and of its aims and aspirations". Not an appeal for funds! That will come later, and the University is confident, we are told in a "Foreword" signed by the Chancellor, the Earl of Athlone, and the other high officers of the University, "that in due time money will be forthcoming from its friends and from all who esteem learning and scholarship".

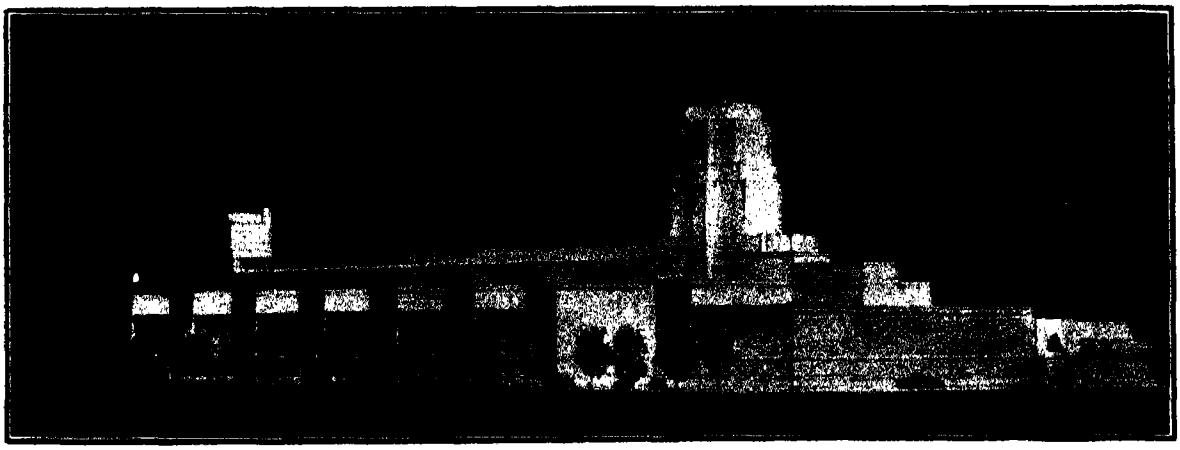

FIG. 1.—View of a model of the proposed buildings in Bloomsbury for the University of London, showing the main features of the general design.

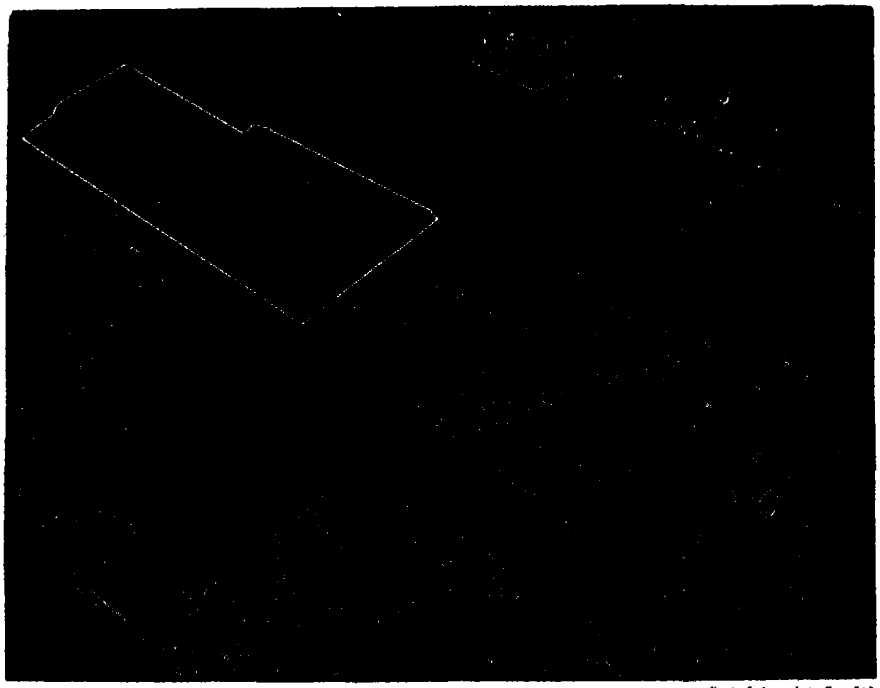
How peculiarly Victorian is the early history of the University of London! Founded in 1836 by Royal Charter, the University was in one sense a Government bureau, accommodated, rent free, in quarters provided by the Government. "For some thirty years", the writer of the pamphlet states, "it discharged its modest duties in modest apartments in Somerset House. From 1870 to 1900, it had a home of its own when it was housed in a building erected at the expense of the Government in Burlington Gardens, now occupied by the Civil Service Commission." The point is not of essential importance, but this account of the early migrations of the University does not tally with that given in the Calendar (1928–29). "From the beginning", we are there informed, "the Government accepted the responsibility for housing the University, and at first apartments were provided in Somerset House, which were also occupied by various learned societies; but in 1835 the Senate were deprived of these and housed in what was described as a '*miserable garret in Marlborough House*'. This accommodation was of a temporary nature only, and in the spring of 1855 the University again removed this time to Burlington House."

Powerful influences were brought to bear on the Senate of the emancipated University—it was reconstituted as a teaching university under the Act of 1898—to induce it to agree to the removal of the University headquarters to the partially derelict building of the Imperial Institute at South Kensington. Without any question the accommodation offered in that beautiful building was in many ways superior, especially for examinations. H. G. Wells used his caustic pen to denounce the old University building, dusty, desolate and empty, the thin permanent odour of dogfish and rabbits pervading the library, in which practical examinations were held; and to express his surprise that any person should oppose any sort of reform for the University of London. Moreover, the accommodation in the Imperial Institute was much more extensive, and this no doubt explains the famous Treasury minute of Feb. 16, 1899, giving a guarantee that the accommodation to be provided would include "such provision as may hereafter be needed for the full extension and development of the University under the Statutes and Regulations made by the Commissioners appointed by the Act". This carelessly worded minute proved troublesome in later years. As a fact, when immediate administrative needs were satisfied, there remained a whole floor, and this was used, not very appropriately, as a research laboratory for physiology, directed for many years by Prof. A. D. Waller. When the accommodation problem became acute, the laboratory was abolished *sans phrase*, the staff pensioned, and the valuable apparatus given away. Perhaps it was well that Dr. Waller did not survive to see this *débâcle*! The point to be emphasised is that

the University always held the Government to its obligation to provide adequate accommodation for its administrative work.

Of course, the real question was not one of providing comfortable rooms for a number of University officials and their clerks, for meetings of committees, and for the examination of candidates. This was recognised by the Royal Commission on University Education in London, appointed in 1910, generally known as the Haldane Commission. So impressed was the Commission by the inadequacy of the administrative headquarters of the University in the Imperial Institute that this question was made the subject of a special preliminary report dated Dec. 15, 1911. One would have expected that on the sound principle enunciated by the cookery book author, " First catch your hare ", it would have appeared expedient to the Commissioners to ensure the reconstitution of the University, and to define its new duties, before considering the question of accommodation, a matter not directly within their terms of reference.

The Haldane Commission in its preliminary report strongly urged that a site should be secured of sufficient size to allow a large measure of freedom in determining the nature of the buildings to be erected, including such scientific institutes as had been referred to earlier in the Report, if these should be found to be necessary or desirable. Both in the public interest and in the interest of the University, the Commission said, buildings should be erected for a reconstituted University, " which would be a visible sign of its recognition as a great public institution ". Be it understood, however, that the Commission at this stage did not recommend the Bloomsbury site. Apparently a friend of Lord Haldane's made investigations, and was able to convince him that this was the most suitable site—at this time it was the 2½ acres forming the southern part of the site—whereupon, having secured the personal approval of Lord Rosebery, Chancellor of the University, he began to collect money for the purchase of the site. These proceedings caused much dissension within the University. On Presentation Day (May 7, 1912) the Principal, Sir Henry Miers, was able to announce that £355,000 had been offered towards site and buildings. Alas! those golden sovereigns have been used for other purposes. Many alternative sites were considered, notwithstanding the view expressed by the Haldane Commission in its Final Report dated March 27, 1913, that the most suitable and convenient quarters for the central University buildings would be found in Bloomsbury. Guerrilla warfare was maintained until the outbreak of the War of 1914–18.



Central Aerophoto Co., Ltd.

FIG. 2.—British Museum and the site (enclosed in a white line) of the University of London. From " University Reform in London ".

We do not question the wisdom of the writer of the pamphlet in scattering the poppies of oblivion over the period 1911–1932, years of controversy, of war, of reconstruction—assuredly years of great progress in university education in London. Twenty have passed before the Royal Commission's dream has taken form and substance in an architect's model; and Lord Haldane and most of his colleagues, including Lord Milner, Sir Robert Morant, and Sir William McCormick, have not survived to see this Pisgah-view. If we lift the veil, it is to honour those to whom they handed the torch—particularly Mr. H. A. L. Fisher, who in 1920, while president of the Board of Education, moved the Government to offer the site to the University. " The Government ", he wrote on April 7 of that year, " are now in a position to acquire a site of about 11½ acres behind the British Museum, and they offer to devote it gratis and in perpetuity to the provision of a site for new headquarters of the University and for colleges and institutions connected with it, including King's College, whose premises in the Strand are now inadequate for its needs." After the five years' grace allowed by the Government, the University found it could not satisfy the conditions attached to the gift, particularly in regard to the removal of King's College, and therefore refused the site, which was re-sold to the Duke of Bedford. It was a black

day for the University, perhaps the blackest in its history. But as Mr. H. V. Lanchester wrote (*New Troy*, June 3, 1926):

"So our Site has gone back to the Duke of Bedford. This does not mean that it might not yet be reclaimed if the will to do it were there. The Duke is in no way antagonistic to the scheme, and the only difference in the position is that the Government offer, to the value of half-a-million or so, is in abeyance, for it seems inconceivable that were a reasonable programme put forward, any Government would fail to offer substantial assistance."

The position soon became desperate. The Duke had signed a few long leases of houses on the site, some of which, we believe, still remain in alien hands, and was on the point of signing building leases. Victory was snatched from a stricken field by the Vice-Chancellor, Sir William Beveridge, who secured a most generous benefaction from the Rockefeller Foundation for the purchase of the site. In addition, a substantial contribution was made by the Government, which thus gained release from its putative obligation to provide for the housing of the University; and the London County Council, after coquetting with alternative sites, including Somerset House and Holland Park, offered openhanded co-operation for the Bloomsbury policy. On May 11, 1927, at the annual graduates' dinner, Lord Eustace Percy, president of the Board of Education, announced the purchase of the site. Let us remember with gratitude those who saw the vision—Gregory Foster, Haldane, Rosebery, Morant, McCormick—and congratulate those whose privilege it will be to transmute the vision into perdurable stone.

The dust of the site controversy has settled. The University is reconciled to Bloomsbury, even when it is described by the official historian of King's College as "an obscure and decaying suburb, off all the main lines of traffic and difficult of access"! But controversy follows controversy. For what purposes are these vast buildings to be used? We turn for information to the official pamphlet, not without misgiving. In addition to the administrative accommodation, there is to be a spacious and well-equipped library building, worthy of the treasures it will hold; and adjacent, but forming a part of the whole design, will be brought together a number of other University institutions. These include the Institute of Historical Research, the Courtauld Institute of Art, the School of Oriental Languages when it leaves its present building in Finsbury Circus, the School of Slavonic Studies, the Institute of Education (formerly the London Day Training College), and Birkbeck College. There will be a Great Hall, facing Russell Square, and accommodation for the Officers Training Corps and the University Union.

An ambitious programme—but the reader of NATURE will at once ask, what provision is to be made for scientific research? We have seen that the Haldane Commission in its preliminary report contemplated the possibility of scientific institutes. Before reaching the stage of the final report, other counsels prevailed. "Special research institutes", it declared, "should not form part of the University organisation." In the opinion of the Commission, the proposal supported by the Medical Committee of the British Science Guild for the establishment of post-graduate laboratories "would be full of danger to the development of the University". In a letter to the *Times* (Nov. 1, 1913), not long after the publication of the Final Report, Dr. A. D. Waller expressed an opinion which we believe will be generally shared by readers of NATURE. "My own opinion," he wrote, "confirmed by the experience of my last 12 years of work at the University—agrees with the opinion expressed in the report of Lord Cowper's Commission to the effect that the establishment of institutions for research was the only way in which existing defects could be supplied . . . and would not in any degree affect injuriously the course of ordinary teaching or discourage the spirit of research in the university schools, but would, on the contrary, promote throughout the university and its other institutions that zeal for the advancement of knowledge which is the highest mark and aim of university training." Nor are we told in the official pamphlet whether suitable and well-equipped lecture theatres are to be provided in the new buildings, where professors could give their inaugural lectures and foreign scholars could communicate the results of their researches. The Haldane Commission expressed a definite view on this question—"We are of opinion that several, though not a large number, of commodious lecture halls should be provided in the central buildings to be first erected". A school of law, a school of music, and a school of journalism are a few of the other institutions which might stake claims on the site.

Of the architectural merits of Mr. Holden's design, we cannot claim to express an expert view. Certain questions the layman, the *homme moyen sensuel*, may be allowed to ask. First, what reasons caused the University to abandon its declared policy of holding a world-wide competition for the best design—a graceful compliment to the most generous donor for the purchase of the site—followed by a competition limited to architects of selected designs and to a small number of architects specially invited to compete? That the Court of the University should take upon itself the selection of an architect is a procedure contrary to all the traditions of the University. Secondly, ought not the members of the University, and the public generally, to insist that the building shall express its idealistic purpose—that long tradition of the search for knowledge, Abelard drawing seekers after truth to Paris, *alma mater* of our universities; Roger Bacon in his tower on the Isis; Newton on the Cam "voyaging through strange seas of thought, alone"; Michael Faraday, London's own man of science, an original member of the Senate of the University of London, who could not afford to get rich, but added untold millions to the wealth of the world; Lister, a graduate of the University, of whom it has been said that no man has done more to relieve human suffering; Ramsay, a professor

of the University, discovering argon and helium in his laboratory at University College; Jeans, a member of the present Senate, peering over the edge of the universe. . . .

We do not suggest that the architect of the new University building should attempt to recapture —in Bloomsbury—the last enchantments of the Middle Age. If he succeeds in capturing the spirit of the present age, he will deserve his niche in the Pantheon of architects. Questions of style apart, air, sunlight, and accessibility are crucial in considering the design. Is it wise, from these viewpoints, to build a single huge building, possibly the largest in London, a break-air, if the word may be coined? Science has not yet discovered any effective method of ventilating a great building with numerous wings—witness the Houses of Parliament. On this question it is possible to appeal to expert opinion. Three distinguished architects in their lay-outs for the site have provided a forecourt and abundant internal air space.

Mr. H. V. Lanchester's sketch of "the University of the Future" showed a forecourt flanked by offices and library and facing the hall and institutes with a dome and two graceful towers. Prof. A. E. Richardson, professor of architecture in the University, adopted a somewhat similar lay-out in a brilliant impromptu sketch, the forecourt facing the Great Hall, not crowned with a dome or tower, a feature he regarded as wasteful and unnecessary. Prof. S. D. Adshead, professor of town planning in the University, prepared a sketch showing an open space running through the site north and south, broken only by arches. He did not consider there was sufficient space for a Great Hall. "Should a great hall ever be built in the neighbourhood," he said in a paper read to the Town Planning Institute (April 29, 1927), "I think it should occupy one of the adjoining residential blocks." This view has been endorsed by Mr. Holden, who has sited the Hall on the part of the site facing Russell Square. All these architects have recognised the importance of Sir John Burnet's columned northern extension of the British Museum in relation to the University building. Mr. Holden's design presents to this frontage of the Museum the least dignified part of its anatomy, as will be seen from the photograph. Whatever else may happen, this should be rectified. We should prefer, however, that the idea of a single great building should be abandoned and an alternative design adopted treating the problem in a more free and characteristic way. T. LL. H.

News and Views

Sir Joseph Larmor, F.R.S.

SIR JOSEPH LARMOR, whose resignation of the Lucasian professorship of mathematics in the University of Cambridge is announced, succeeded Sir George Gabriel Stokes in the chair in 1903. Stokes had been elected so long ago as 1849, and one of the early acts of his successor was to edit his "Scientific Correspondence" (2 volumes, 1907). After being Senior Wrangler in 1880 and first Smith's Prizeman, Mr. Larmor (he was knighted in 1909) was elected to a fellowship in St. John's College and was appointed professor of mathematics at Galway, but in 1885 he returned to Cambridge as College and University lecturer in mathematics. "Æther and Matter" appeared in 1900, and his election as secretary of the Royal Society in 1901 (he had been a fellow since 1892) was a recognition of his eminence as a mathematical physicist. Scientific papers have continued to flow from his pen since 1881 or before, but the long-hoped-for treatise on electrodynamic theory did not materialise. The works of many younger men, however, clearly show the inspiration which they derived from his lectures. In 1929 the Cambridge University Press published two handsome volumes of "Mathematical and Physical Papers", with Sir Joseph's own comments in the form of notes and appendices; a glance at the table of contents will give an idea of his enormous range of interests. In addition, his frequent letters in NATURE and elsewhere, though as a rule not easy to understand, have always been worth serious consideration.

THOSE who were privileged to be present will not readily forget the inimitable, racy address which Sir Joseph gave in the Arts School in Cambridge at the Clerk Maxwell Celebration in October 1931; it was quite different from the paper, "The Scientific Environment of Clerk Maxwell", published in the Commemoration Volume, and this in turn is only an extract from a more extended investigation into the historical origins of thermodynamics and the kinetic theory which, it is hoped, will soon be published. One of the duties of the Lucasian professor, as of the other professors of mathematics in Cambridge, is the reading of the essays submitted year by year for the Smith's Prizes; and thus Sir Joseph has kept constantly in touch with the best of the younger Cambridge mathematicians. Perhaps he has occasionally been a little out of sympathy with some of the recent developments in pure mathematics, but he has always been ready with advice and encouragement; in particular, the succession of Isaac Newton Students have reason to bless his name. From 1911 until 1922, Sir Joseph sat as member of Parliament for the University of Cambridge, and other administrative duties, in the University and elsewhere, have been thrust upon him and conscientiously discharged. A congenial office has been his chairmanship, in the absence of the Vice-Chancellor, of the Observatory Syndicate and the Solar Physics Committee in Cambridge; he always seems thoroughly to enjoy presiding over the body of distinguished men of science who assemble once a year to lunch with the professor of astrophysics and discuss the affairs of the Solar Physics Observatory. It is to be hoped that Sir Joseph's retirement from his professorship will not mean his leaving Cambridge, for his College and the University can still profit by his services.

Geological Society Elections

THE following have been elected foreign members and foreign correspondents of the Geological Society of London: Prof. R. A. Daly, Sturgis Hooper professor of geology in the Museum of Comparative Zoology at Harvard College, an authority on igneous rocks and mountain building and on coral reefs; Prof. Paul Niggli, University of Zurich, distinguished for his work on ore deposits and crystallography; and Prof. Bailey Willis, Stanford University, known for his work on geological structures, to be foreign members of the Society. Prof. C. P. Berkey, Columbia University, New York City, secretary of the Geological Society of America, who has carried out geological studies in Mongolia and elsewhere; Prof. H. A. Brouwer, University of Amsterdam, known for his work on the geology and petrology of the Dutch East Indies; Prof. Hans Cloos, University of Bonn, an authority on the tectonics of igneous intrusions; Prof. W. K. Gregory, curator in the American Museum of Natural History, New York City, distinguished for his studies on fossil vertebrates; and Dr. Victor Van Straelen, director of the Natural History Museum in Brussels, distinguished for his work on fossil Crustacea, to be foreign correspondents of the Society.

Beilby Memorial Awards

AWARDS are made from time to time from the interest on the Beilby memorial fund to British investigators in science for original work, preference being given to the investigation of problems connected with fuel economy, chemical engineering, and metallurgy. The administrators of the fund have just awarded £105 each to Mr. W. J. Rees, of the Department of Applied Science in the University of Sheffield, and Dr. W. R. Schoeller, metallurgist, Messrs. D. C. Griffith and Co., London. Mr. Rees was educated at George Dixon Technical School, Birmingham, and at the Royal College of Science, London. In 1901, he became assistant to Dr. Walter Rosenhain, in the laboratories of Messrs. Chance Bros. and Co., Ltd., at Birmingham; in 1906–17, he was chief chemist to the same company, and since 1917 he has been lecturer in charge of the Department of Refractory Materials in the University of Sheffield. He is an honorary member of the British Cast Iron Research Association, to which he was elected in recognition of services rendered in connexion with research on moulding sands; and hon. secretary of the Refractories Association of Great Britain. Dr. Schoeller was born at Antwerp and educated in Belgian State schools at Antwerp and Tournai. He studied chemistry at the Polytechnic Institutes at Darmstadt and Stuttgart, and at the University of Greifswald, where he obtained the degree of Ph.D. in 1902. In the following year, he joined the staff of Messrs. D. C. Griffith and Co., assayers to the Bank of England, and in 1909 was naturalised as a British subject. After experience in the United States, South America, China, and elsewhere, he rejoined Messrs. D. C. Griffith and Co., specialising in rare metals. From 1913 onwards, he has devoted much of his spare time to original research work, especially on tantalum and niobium. He is joint author with Mr. A. R. Powell, of "The Analysis of Minerals and Ores of the Rarer Elements".

The Peking Man

AT a meeting of the Geological Society of China on June 28, Prof. Davidson Black made the first public reference to the discovery of parts of *Sinanthropus* other than the skull—an ungual phalanx of the foot found more than two years ago, a clavicle and a semilunar bone (wrist) found last season. The announcement of these discoveries was withheld until the close of the present season's excavations at Chou Kou Tien in the hope that other parts of the limbs might be recovered. This hope has not been realised. Hence an account is now given of the small fragment that seems to demonstrate that the Peking man's hand "differed in no essential respect from our own", of the peculiar obliquely-directed toe-bone, which "makes it probable that the feet differed much more widely from ours than the hands", and of the robust clavicle. On July 5 Prof. Davidson Black left Peking for England to deliver the Croonian Lecture to the Royal Society next December; he is visiting fossil beds in India and Egypt on the way. Before leaving China, he made casts of the five jaw fragments, the complete skull of the youth found in 1929, and of the endocranial cast of *Sinanthropus*, for transmission to London for reproduction, and completed his report on the endocranial cast and its significance. Its capacity is not more than 900 c.c. It reveals the asymmetry claimed to be distinctive of right-handedness. The cast displays many primitive features of exceptional interest, which shed important light on the distinctive characters of the earliest human brain.

Women Graduates in Modern Life

AT the annual reunion on June 30 of the University of Edinburgh Graduates' Association, held in the Women's Union, Sir Josiah Stamp referred to the alumni associations in America as constituting one of the strongest sides of American university life, and said that he hoped the graduates of Edinburgh would similarly endeavour to make the University a real and active part in themselves, letting its influence remain with them and helping it in every way they could. Speaking more particularly to the women graduates, he reflected upon the gravity of the times in which we live and the tremendous importance and value of the collective mental training represented by the graduates who had just been 'capped', mobilised and conserved for the future. While it may be said that the careers of many of these women will be cut short and some people may say all they have done at the University would so be wasted, he considers that a wrong view. Why should not man and wife act together in the great task of thinking out the world's problems, thus making for a higher standard of civic and individual judgment than we have to-day?

The Universities and Civilisation

SIR JOSIAH was emphatic that civilisation is at the crossroads; it may go one way under the influence of mass desire and mass impression, or the other way under the influence of intellectual and moral leader-

ship. If a university is not a great force, if the members of a university are not a great force in that decision, then who is ? Where are we to look for it ? In this crisis in civilisation there is a terrific responsibility on university graduates for elasticity of mind, probity and clarity of judgment, and industry of thought on the concrete issue before them. There are many great issues on moral principles in these days, when the widely-held view is that the proper place for a path is the edge of the precipice. The world is full of good people who are thoroughly muddle-headed ; this is a time for level-headed decisions and carefully worked out ones. Sir Josiah concluded with a call to the students to be true to the great ideals the university has given them ; and to try to make the university what he believes it ought always to be—somewhere where the reasoned thought and soul of our country can have the perpetual association of great ideas, the discipline of serious and persistent aims, the purification of candid and purging humour, and lastly the company of souls that are kindled to noble purposes.

Society for Psychical Research

THE last of the jubilee meetings of the Society for Psychical Research was held on July 4 at the Conway Hall, when Dr. William Brown, Wilde reader in mental philosophy in the University of Oxford, lectured on "Psychology and Psychical Research". The president, Sir Oliver Lodge, took the chair. Dr. Brown said that hypnotic and psycho-analytic investigations have greatly supplemented the theory of the 'subliminal self' first propounded by F. W. H. Myers, one of the founders of the Society for Psychical Research, without, however, really supplanting it. The employment of the statistical method on large numbers of cases is entirely in the spirit of strict science, yet the predominantly negative results recently obtained along these lines as regards manifestations of telepathy and clairvoyance should not blind the public to the possibility of such phenomena in special cases and under special conditions. The intensive study of well-attested individual cases is needed to correct the balance, and it is especially along this line that the Society for Psychical Research has done much useful work. One might base one's belief in survival most firmly on general philosophical and religious considerations as to the nature and value of human experience ; nevertheless, the sum total of evidence of a scientific nature accumulated by the Society for Psychical Research in support of survival is far from negligible.

Marconi Beam Stations for Shanghai

NEW Marconi transmitting and receiving stations are to be erected near Shanghai for the operation of the proposed short-wave beam services between China and Europe and the United States. A unique feature of the installation will be the inclusion of auxiliary Marconi apparatus enabling the transmitters to be utilised for broadcasting services when they are not in use for telegraphic communications. The auxiliary apparatus for this purpose consists of a modulating equipment which can be connected to either of the telegraph transmitters to provide telephone signals of broadcasting quality. A complete set of Marconi studio equipment is also to be supplied to enable the service to be conducted in accordance with the most modern practice. The aerial system of the transmitting station is of particular interest. For the commercial telegraph services to Europe, of which the principal is the service to Great Britain, two bays of beam aerials, accurately oriented to concentrate their signals on the receiving stations, are to be erected, one being tuned to the wave-length of 17 metres and the other to 26 metres, the wave-lengths allotted to these circuits. A third beam aerial array will be directed on San Francisco for the American service. In addition, there will be four omni-directional aerials, one of which will be used for broadcasting. The others are provided to afford the station the maximum flexibility in the range and extent of its telegraphic services. At the receiving station four high-speed commercial service receivers of the Marconi beam type are to be installed, with two beam aerial systems directed on Europe and two on San Francisco. Four omni-directional receiving aerials are also to be supplied for the reception of short-wave signals from other countries with which beam services are not required. On the completion of these stations near Shanghai a direct commercial wireless circuit will be provided for the first time between Great Britain and China.

Emergency Lighting Sets

IN addition to the usual source of electric power for supplying lamps and signalling devices, it is sometimes necessary, in order to safeguard life and property, to have another source of power that can be available in emergency. Such additional sources are necessary for theatres, cinemas, hospitals, and for all large buildings through which there is a continuous stream of traffic. Up to the present time, storage batteries have often been used for this purpose, but their drawbacks are their expense and the gases they develop, often necessitating the use of a large separate room. A petrol electric set has sometimes been suggested, but there is frequently difficulty in starting it after a long period of standstill. Fire risks also impose restrictions in the selection of rooms for these sets. In a recent issue of *Allgemeine Elektricitäts Gesellschaft* (*A.E.G.*) *Progress*, a new emergency lighting set is described which eliminates practically all these difficulties. It consists simply of a small water turbine, which can be connected to the municipal water mains and drives a direct current generator (turbinamo). The water supply to the turbine is normally cut off. Should the normal supply voltage fall for any reason, an electro-magnet ceases to act and so a cut-off device is released, and the pressure of the water in the mains opens a valve and the machine rotates. The water pressure required is anything between 3 and 6 atmos. (42·5-85 lb. per sq. in.). The lighting set has a vertical axis, and takes up very little space. It should be placed near the water supply mains. As a disturbance rarely occurs, and lasts only very little time, the cost of the water used is negligible.

Mechanised Farming

"MECHANISATION and British Agriculture" was the subject of the fourteenth Conference held at Rothamsted Experimental Station, Harpenden, the full report of which has been published and can be obtained on application to the Secretary, price 2*s*. 6*d*. In these times of agricultural depression, the use of labour-saving machinery and implements is one of the most feasible means by which farmers may reduce their costs, and the appliances available and their probable lines of development are described by Mr. J. E. Newman, of the Oxford School of Agricultural Engineering. Successful practice in the new cereal husbandry is set out in a series of papers by leading farmers, the record of whose experience is of the utmost value. The question of live stock is not, however, overlooked, and Prof. J. A. S. Watson contributes a stimulating account of the combination of animal husbandry with mechanised farming. The maintenance of soil fertility under the frequent growth of cereals is the subject of a paper by Sir John Russell, who discusses, amongst other problems, the most economical means of restoring to the soil the surplus straw which is now an encumbrance on the large cereal farms. The booklet contains a full account of the discussion following the papers and a summary of the agricultural problems involved.

Prehistoric Pot-Boilers

MR. WILFRED L. BULLOWS, of Streetly, Warwickshire, adverting to a reference to flint pot-boilers by Sir Arthur Smith Woodward in his article on fossil man in China (see NATURE, May 28, p. 784), writes to point out the unsuitability of flint for this purpose. In the course of an investigation of a prehistoric cooking site in Sutton Park, Warwickshire, in 1926, Mr. Bullows carried out a number of experiments with the view of ascertaining the methods probably employed in making use of several cooking pits which had been discovered on the site under mounds of broken stone of an undoubted antiquity. On a considerable area of ground laid bare by a fire which had taken place a few years previously, there were found not only a number of cooking pot-holes, oval in shape and of an original depth of about 1½ ft., but also hearths for heating the stones, as well as ridges of stone, which probably represented the clearings of the cooking pots. The pot-holes had not been lined with clay; but evidently undressed skins had been used as a lining, the shape of the hide probably being responsible for the oval shape of the pit. In a trial in a small pit lined with a sheepskin, it was found that four gallons of water could be raised to boiling point with heated stones in about forty minutes. Fifty pounds of stones, each weighing from two to three pounds, were required. The stones used here by prehistoric man were quartzite pebbles from the Bunter pebble beds, and the same kind of stone was used in the experiment. Flints were found to be useless, as not only did they split alarmingly in the fire, but sudden contraction in cold water reduced them almost to powder. A report by Mr. Bullows on his investigation of this interesting site in Sutton Park and its bearing on methods of cooking by the use of heated stones appeared in *Trans. Birmingham Archæol. Soc.*, vol. 52, pt. 2, 1927.

Egypt Exploration Society's Exhibition

THE exhibition of archæological finds during the past season, now open at the Wellcome Historical Medical Museum, Wigmore Street, London, covers the work of the expeditions of the Egypt Exploration Society at Abydos, Amarna, and Armant. At Abydos, the Society, working in co-operation with the Oriental Institute of Chicago, is engaged in copying the frescoes of the temple of Seti. The work is in the hands of Miss A. M. Calverley and Miss M. F. Broome, who contribute a magnificent series of paintings as the result of their activities during the past winter. The exhibits from Amarna include a number of photographs, some taken from the air; frescoes which have been restored skilfully; statuary of the age of Akhenaton, mostly broken by his successors, and profiles engraved on limestone, which are thought to be sculptors' trial pieces. Among the other miscellaneous objects included from this site are glass, pottery, and ostraka of the Roman period. At Armant the most remarkable finds were the predynastic plaster 'flags' already familiar from the published description by Mr. O. H. Myers, director of the excavation. Slate palettes, black-topped ware in remarkably good preservation, other pottery, and flints are of a more familiar character than painted skulls and two hippopotami in pink limestone which accompanied them.

Habits of the Pangolin

How the Indian pangolin combines attack with defence is told by Mr. W. G. Adam in the *Field* for June 11, p. 882, in an article on the species as studied by him in Ceylon, of which island it is a native. When rolled up in the defensive position with its tail turned forward, it keeps up a slapping and grinding movement with that member, and if this results in any part of the assailant's body being caught between its own body and tail, begins a sawing movement of the latter which, the scales of the body and tail being opposed in the rolled-up position, inflicts a severe wound. Whether this act be due to instinct or intelligence, the pangolin seems to be an animal of fairly high mentality and advanced instincts. Both male and female care for the young ones, and Mr. Adam has seen the pair jointly hunting for a strayed one by scent and carefully convoying it home when found. Moreover, a young pair stayed about his premises in a semi-domesticated condition for more than a year, recognising strangers with squeaks, but answering to names with those they knew, while the female would even let puppies play with and pull her about.

Woad as a Crop Plant

PLANTS and animals when taken under man's care have to face natural selection in a new and special form, the struggle now being to retain his favour against competitors in cultivation and against his inventions. That highly historical dye-plant, woad, has at last succumbed in this conflict, according to an

article by Mr. A. W. Exell in the *Gardeners' Chronicle* for June 18, p. 403. Last grown in France in 1887, its cultivation in Germany had ceased about twenty years before this date, but was continued in England, in spite of the competition first of natural and then of synthetic indigo, for many years later, the product being used in the dyeing of police and naval uniforms. The industry had, however, long been a declining one, and in 1930 only two farms, both in Lincolnshire, were growing woad. Of these, one ceased to do so last year, but the other raised a small crop; this year none at all has been grown, and Mr. Exell thinks the day of woad as a crop-plant is over, though some stock of the prepared product is still left. Woad was an expensive crop to raise, and the labour and land devoted to it have been diverted to the production of potatoes and sugar-beet.

William Morgan

MR. PALIN ELDERTON in a recent lecture to the Faculty of Actuaries (*Trans. Fac. Act.*, **14**, 1932, pp. 1-20) gave an interesting sketch of the life of his distinguished predecessor William Morgan, who became assistant actuary of the Equitable in 1774, actuary a year later, and retired so long after as 1830. Morgan, who was a self-taught mathematician, owed his appointment to the famous Dr. Richard Price, whose biography he wrote (not, according to Mr. Elderton, very well), and although some of his mathematical work in connexion with joint survivorships might not have commended itself to better trained mathematicians, it was, writes Mr. Elderton, "the first serious attempt to obtain a general solution to the problems of survivorship, and had the merit—a great one indeed—of giving expressions that could be used to obtain arithmetical results from any mortality table".

Pharmacy in Scotland

THE forthcoming British Pharmaceutical Conference at Aberdeen on Sept. 12-16 has been the chief influence in the choice of material for the handsome special issue of the *Chemist and Druggist* for June 25. The majority of space has been devoted to various phases of Scottish activity from the point of view of pharmacy. An interesting account of the early history of pharmacy and the apothecary in Scotland is given by Dr. Thomas Ferguson. The cod-liver oil industry of Aberdeen and the extraction of the oil in Newfoundland are described, with useful illustrations. The appreciation of Aberdeen, the host city for the 1932 Conference, is well worth reading, and the illustrations (in photogravure) of its streets, industries, and colleges are very striking. Among the more descriptive articles is an illustrated account of the British Drug Houses, Ltd.

Announcements

THE following Royal Society research appointments are announced: Mr. C. N. Hinshelwood, Trinity College, Oxford, and Dr. M. L. E. Oliphant, Trinity College, Cambridge, to be Messel Research Fellows. Dr. W. Hume-Rothery, Magdalen College, Oxford, and Dr. A. J. Bradley, University of Manchester, to be Warren Research Fellows.

THE fourth Victor Horsley Memorial Lecture of the British Medical Association will be delivered by Prof. E. D. Adrian, on "The Visceral Sense Organs", at University College Hospital Medical School, Gower Street, London, W.C.1, on July 20, at 5 P.M. Admission to the lecture is free on presentation of a visiting card.

IN connexion with the centenary meeting of the British Medical Association at London, the popular lecture will be delivered by Prof. Julian Huxley in the Great Hall, University College, Gower Street, W.C.1, on July 29. The subject of the lecture will be "The Biology of Human Nature". Tickets can be obtained from the Organising Secretary, British Medical Association Centenary Offices, Tavistock House (North), London, W.C.1.

THE first Hinchley Memorial Lecture of the Institution of Chemical Engineers will be delivered on Oct. 28 by Mr. H. T. Tizard, Rector of the Imperial College of Science and Technology, on "Chemical Engineering and the Aircraft Industry". These lectures have been inaugurated to commemorate the long and intimate association of the late Prof. J. W. Hinchley with the Institution, and will be delivered at intervals of three years.

AN International Conference on Social Work is to be held at Frankfort-on-Main on July 10-14. The main theme of the conference will be "The Family". The work of the Conference will be divided among six commissions dealing with health services, educational influences, economic insecurity, and other subjects. Arrangements for British delegates have, at the request of the British National Committee, been undertaken by the Institute of Sociology. Particulars can be obtained from Miss E. W. Spear, Secretary, Institute of Sociology, Le Play House, 65 Belgrave Road, Westminster, S.W.1.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A head of the Department of Mathematics and Physics at the Polytechnic, Regent Street, W.1—The Director of Education, The Polytechnic, Regent Street, W.1 (July 11). A head of the Chemistry Department at Sunderland Technical College—Chief Education Officer, Education Offices, 15 John Street, Sunderland (July 11). A chemist in the Department of Government Chemist—The Government Chemist, Clement's Inn Passage, Strand, W.C.2 (July 16). A poultry pathologist in the Department of Agriculture and Horticulture at the University of Bristol—The Agricultural Officer, The University, Bristol (July 16). A biologist for the biological survey of the Hampshire Avon—The Registrar, University College, Southampton (July 16). A lecturer in chemical engineering in the Department of Chemical Engineering at the Imperial College of Science and Technology—The Registrar, Imperial College of Science and Technology, London, S.W.7 (Sept. 9).

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

New Evidence for the Neutron

SEVERAL important communications dealing with the properties of rays emitted by atomic nuclei when bombarded with α-particles have recently appeared,[1] on which we should like to make a few comments.

It has been shown by F. Joliot [2] that the rays emitted by boron under the action of α-particles from polonium are much more penetrating than had originally been indicated. Their penetrating power, while superior to that of the most powerful γ-rays obtained from radio-active sources, is inferior to that of the rays obtained from beryllium bombarded by α-particles from polonium. This result does not agree with Webster's findings, but agrees with the fact that the protons ejected from boron are slower than those ejected from beryllium. Secondly, we have shown that the ejection of protons is a general phenomenon. By means of the Wilson chamber, we have photographed the paths of the helium nuclei ejected by beryllium rays, and from absorption measurements were able to conclude that other atoms are also ejected. Further, our experiments showed for the first time the important part played by the nuclei in the absorption of the rays emitted by beryllium under the influence of α-particles, a phenomenon which clearly marked them off from all previously known radiation.

J. Chadwick was led simultaneously to the same generalisation concerning the ejection of nuclei, and he put forward the view that the penetrating rays produced by the bombardment of beryllium by α-particles from polonium are neutrons. This interpretation is necessary if energy and momentum are conserved in the collision.

Recent experiments which we have carried out with M. Savel clearly show that the rays emitted by lithium have a penetrating power, in lead, less than that of the γ-rays of polonium (they are completely absorbed by 5 mm. of lead), and that they are much more readily absorbed, at equal surface mass, by paraffin than by lead. This proves that they cannot be of an electronic or electromagnetic nature. Since for various reasons it is extremely improbable that we are dealing with hydrogen nuclei or α-particles (the energy of which would be enormous), these results prove—*independently of the ejection of nuclei and the laws of elastic collisions*—that the rays emitted by lithium under bombardment by α-particles from polonium are different from previously known radiation and are probably neutrons. The above reasoning does not apply to the rays ejected from beryllium, boron, or to those emitted by lithium when bombarded with the α-rays from the active residue of radium,[3] because in such cases we do not have γ-rays of equivalent penetrating power, for comparison.

Our latest experiments, in collaboration with M. Savel, indicate that the protons ejected from beryllium form two groups. This suggests that there are also two groups of neutrons (each group not necessarily homogeneous); one group has a range of 28 cm. in air, and an energy of $4 \cdot 5 \times 10^6$ electron volts; the other has a range of about 70 cm. and an energy of approximately $7 \cdot 8 \times 10^6$ electron volts. We find it difficult to reconcile Chadwick's result of a *maximum range* of 40 cm. with the curves which we have obtained for the absorption of protons.

The mass of the neutron calculated by Chadwick [4] (based upon the experimentally estimated energy of the neutrons from boron), according to the reaction $B^{11} + \alpha = N^{14} + n$,[5] is about 1·006 (He = 4), and the atomic mass of Be^9, based on the energy of the fast neutrons ($7 \cdot 8 \times 10^6$ ev.), is 9·006. This suggests that the binding energy between the two α-particles and the neutron in the Be^9 nucleus is relatively weak. Further, we know that the rays emitted by beryllium are composed of neutrons and photons, and we may therefore suppose that they are emitted simultaneously according to the equation

$$Be^9 + \alpha = C^{12} + n + h\nu.$$

The photons of 2 to $4 \cdot 5 \times 10^6$ ev. energy, which we have detected, would correspond to the group of neutrons of maximum energy $4 \cdot 5 \times 10^6$ ev. (protons having a range of 28 cm.).

Concentration of Slow Neutrons in the Atmosphere

RECENT evidence [1, 2] of neutral particles of atomic mass and great penetrating power suggests the possibility that terrestial matter may contain similar particles of low (thermal) energies, undetected hitherto by reason of their small interaction with matter. While it has been argued that neutrons of mass 1 would rapidly escape from the earth, one would hesitate to deny the possible existence of similar bodies of greater mass, and it seems pertinent to remark that experimental evidence already exists which, if we knew the laws of collision of neutrons with matter, would at once fix an upper limit to their concentration in the atmosphere.

Consider a gravitation experiment of the Michell-Cavendish type and suppose the large attracting masses to be heated above room temperature. If the atmosphere contains a constituent enjoying relatively free passage between the 'attracting' and the 'suspended' masses, but, nevertheless, capable of some slight exchange of momentum with them, a radiometer repulsion should be experienced by the suspended masses. The arrangement constitutes, in fact, a radiometer pressure-gauge. Let m be the mass of a neutron, M, M' those of atoms of the 'attracting' and the 'suspended' bodies respectively, T' the temperature of the attracting bodies, and T that of the remainder of the system. Let us suppose that $m \ll M$ and $\ll M'$ and that the scattering of the neutrons by the atoms is elastic and nearly isotropic.[3] The law of scattering is then that for the elastic collision of a light with a heavy sphere, and it becomes possible to calculate the average rate at which momentum is exchanged between the two atoms, provided that the free path of the neutron is so great that multiple scattering in any one of the bodies is negligible. If the collision cross-sections for a neutron with the atoms in question are a, a', the average force on the atom M' due to the excess temperature of the atom M is found to be approximately

$$\frac{2paa'}{\pi^2 r^2}\left(\sqrt{1+\frac{8}{3}\frac{m}{M}\left(\frac{T'}{T}-1\right)}-1\right) \text{ dynes,}$$

r being the distance between the two atoms and p

(dynes . cm.$^{-2}$) being the 'partial pressure' of neutrons in the atmosphere. The presence of neutrons should thus entail an apparent decrease of the Newtonian gravitational constant with rise of temperature. The experiments of Shaw[4] (who found a small increase of gravitation with temperature) show that, if M refer to lead and M' to silver, a negative temperature-coefficient of more than 5×10^{-5} per °C. is improbable. If for illustration we put $m/M = 1/200$, $a = a' = 10^{-25}$ cm.^{2}, we find that $p < 5 \times 10^{-6}$ of an atmosphere. The correct cross-sections for slow neutrons are not yet known.

Currents produced by the Gills of Mayfly Nymphs

BABAK and Foustka[1] were able to show that the movements of the gills of ephemerid nymphs were dependent on the oxygen tension of the water. Later, Dodds and Hisaw[2] demonstrated a relation between the gill area per gram weight of the animal and the oxygen tension of the water inhabited by these animals. That the currents produced by the gills might differ in different species, and that such currents might have an adaptive significance, appear to have escaped notice.

The following five species from stagnant and running waters are being examined: *Chlœon dipterum* and *Leptophlebia marginata* as examples of pelagic animals in stagnant water; *Ephemera vulgata*, a form burrowing in fine mud or sand in running water; *Ecdyonurus venosus*, associated with fast streams with stony beds; and *Cœnis horaria*, a form which burrows in fine mud to such a small depth that the gills are left exposed in the water at the mud surface.

In each case the gills move in metachronial rhythm, and problems comparable with those elucidated by Cannon and Manton[3, 4] on the feeding mechanisms of Crustacea are presented.

The erect plate-like gills of *Chlœon* moving in metachronial rhythm create differences of pressure in the intergill spaces. Thus in any intergill space a period of suction is followed by a period of compression. The main result of this is a symmetrical current passing backwards over the abdomen and outwards in an upward direction between the gills. The last gills are stationary and act as buffers, directing the current strongly to each side. This prevents the setting up of eddies near the animal in that region and ensures that the same water will not be used again for respiration.

In *Leptophlebia* it is not yet clear how far pressures set up between the gills are significant, since the gills lie at different angles to the body. The gills act as paddles, and by their rotation throw water over themselves from in front, or the sides of, or from beneath the body to the middle dorsal line. Since the gills are moving at different levels of the water opposite the several segments of the abdomen, water from all regions round the body is explored for respiratory purposes.

Ephemera in its mud tunnel creates a simple posteriorly directed current over the dorsal side of the abdomen. The gills are held upwards over the back in a roof-like manner. Moving in metachronial rhythm from before backwards, they press backwards the column of water beneath them and thereby set up a rapid current very appropriate for a creature with such burrowing habits.

The gills of *Ecdyonurus* project postero-laterally from the body. Lying in the angles between the broad hind femora and the abdomen these gills are protected from the rapid flow of water in which the animal lives. There is little difference of phase in the metachronial movement of the gills. The current produced passes from the outer sides of the body upwards between the gill plates to the mid-dorsal line. The animal commonly faces upstream, and the environmental flow of water thus assists in the removal of the 'gill current' along the animal's dorsal side to the posterior region.

Cœnis possesses a pair of elytroid protective gills. These are held upwards at an angle of about 40°, while the remaining four pairs of gills, behind and beneath

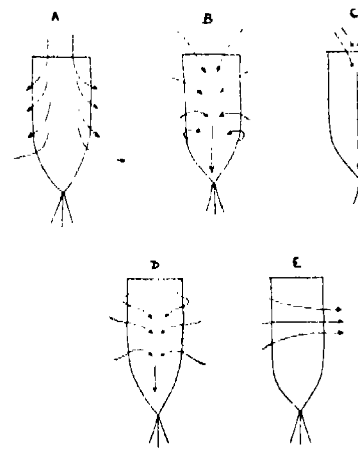

FIG. 1.—Diagrams of currents over the abdomen in A, *Chlœon dipterum*; B, *Leptophlebia marginata*; C, *Ephemera vulgata*; D, *Ecdyonurus venosus*; and E, *Cœnis horaria*.

them, beat in metachronial rhythm. In this form, as opposed to all the others mentioned, the current is asymmetrical. It flows in between the moving gills, beneath the 'elytra' at one side and out at the other. To this fact may be related a remaining one. Whereas, in the first-mentioned species, members of a pair of gills beat simultaneously, here the members of a pair of gills in motion are out of phase with each other. Thus, in addition to a metachronial rhythm along the animal, there is a similar rhythm from side to side in two elements of a pair.

The details of the above phenomena are being investigated with the aid of the stroboscope.

Discontinuous Distribution in Bees

IN 1898, I described a new genus of bees, *Hesperapis*, based on a species found in New Mexico. Since that time, sixteen other species have been referred to this genus, which proves to be especially characteristic of the south-western deserts, in California, Lower California, and adjacent regions. In 1911, Friese described a genus, *Capicola*, from the deserts of South Africa.

Last year's African Expedition led to the discovery of no less than seven new species in South Africa, the localities being Graaff-Reinet, Calvinia, Nieuwoudtville,

and Van Rhyn's Pass. One of these species, collected by Miss Alice Mackie, I have named *Capicola aliceæ*. The female has the clypeus with a median sulcus; hind tibiæ and tarsi red; spur of mid tibia with about thirteen oblique closely set fine spines; hair at apex of abdomen black. The male has the hind tarsi reddish; hair at apex of abdomen not black; sixth sternite light red, strongly bilobed. The species comes from Calvinia and Nieuwoudtville. It was when describing this species that I was struck by the extraordinary resemblance to the American *Hesperapis*. On making comparisons, I failed to find any generic character to separate *Hesperapis* from *Capicola*. This was so extraordinary that I sent a pair of *C. aliceæ* to Mr. P. H. Timberlake, of California, who has a much larger collection of *Hesperapis* than anyone else. He made a minute study, including the genitalia, and now reports (May 12):

"My conclusion is that *Capicola* is exactly the same as *Hesperapis*, and the distribution is of course very extraordinary. Perhaps the genus is a very ancient one, formerly wide spread, but has mostly died out, except under desert conditions. If that is so, why does it not occur in the desert regions of Asia? I dissected *C. aliceæ* and found good specific differences to distinguish it from the California and New Mexico species, but certainly nothing generic. All our North American species that I have examined have the genitalia extraordinarily alike, these parts being in fact rather poor for the differentiation of species. *C. aliceæ* has the genitalia of the same type, and in fact there is not a great deal of difference in the ædeagus itself. The eighth ventrite is somewhat more specialised in the South African insect, and the seventh still more so."

Thus *C. aliceæ* must become *Hesperapis aliceæ*. I cite these details in order to show that apparently these insects are truly congeneric, and the resemblances are not due to convergence.

We are reminded of the distribution of the tsetse flies (*Glossina*), which at present live in Africa (we had the pleasure of collecting both *G. palpalis* and *G. morsitans* in the vicinity of Bukama), but in Miocene times were represented by several species in Colorado.

These facts, and others like them, serve to show the enormous antiquity of many insect genera, and at the same time their liability to be exterminated over large areas.

A Hermaphrodite Sea-Urchin

COMPARATIVELY few cases of hermaphroditism have been recorded among echinoids. Gadd [1] has described a specimen of *Strongylocentrotus drœbachiensis* with four segments of the gonad female and one segment male. Gray [2] has described a specimen of *S. lividus* with three segments female and two mixed female and male. He has also described [2] a specimen of *Arbacia pustulosa* which was apparently a castrated male with some secondary female characters.

A specimen of *Echinus esculenteus*, taken in twenty fathoms on the 'Breast' ground, off Port Erin, in April, had four segments of the gonad female and one male. These were all typical in colour—translucent yellowish in the female and ivory-white in the male. In volume and condition also they were typical for the locality, though less full than from inshore specimens. Two of the female segments were joined, but the rest were discrete. These two segments and the one opposite to them were ripe and had full vesicles. The fourth female segment was less full and only about three-quarters ripe. The male segment was ripe and had full vesicles, but was smaller in volume than the ripe female segments. A self-fertilisation yielding normal plutei was obtained. This is the only hermaphrodite which has been found among about three thousand urchins opened in the past year.

Rectilinear Propagation and Diffraction of Electrons

DURING the preliminary adjustment of an electron diffraction apparatus for use with organic vapours, some interesting phenomena were observed.

Fig. 1 is a diagram of the camera; *AB* is 15·8 cm., *BC* is 14.4 cm., and *CP* is 43·8 cm. *A* is a plane,

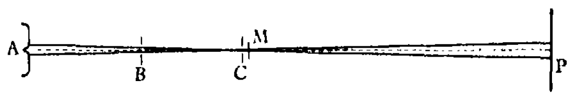

FIG. 1.

highly polished cathode of electron metal (magnesium alloy). *B* and *C* are two circular holes 0·3 mm. and 0·15 mm. in diameter respectively. *M* is a piece of mica showing thin film colours of the first order. *P* is a photographic plate. The space between *C* and *P* was evacuated to 10^{-5} mm. and was only connected to the discharge space ($A - B$) through the holes *B* and *C*. The centres of *A* and *B* and *C* were accurately aligned along the axis of the apparatus, and the plane of *A* was at right angles to same.

After adjusting the discharge so as to obtain a clearly defined cathode beam, using air as the medium, a brilliant diffraction pattern was visible on a fluorescent screen placed at *P*. On enlarging the pattern,

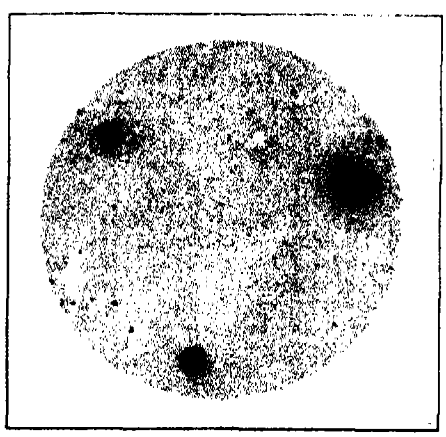

FIG. 2.

the spots were found to consist of a circle with a bright spot at the centre. Fig. 2 shows three of these spots (×3). In the case of this photograph, the diameter of the rings was 0·45 mm. and of the centre spot 0·06 mm., using electrons of wave-length 0·07 A. The small size of the central spots enables very accurate measurements of length to be made between them.

A monochromatic beam of electrons was assured by keeping the high voltage ripple below one-tenth of 1 per cent and the discharge conditions constant. This resulted in clearly resolved diffraction images.

With no mica in the path of the beam, a similar spot with a bright centre was obtained and could be observed directly on the screen through a microscope. On starting the discharge with a fresh cathode, only a single spot of about 0·5 mm. diameter is seen, diminishing in intensity towards the edge. After a few minutes a ring forms, and gradually increases in diameter with the formation of a centre. The centre brightens until the comparatively stable condition shown in Fig. 2 is attained at the end of about an hour of discharge.

These variations in the spot seem to show that we have here a pin-hole picture of the emitting surface of the cathode. The central spot only forms after a minute crater has appeared on the cathode through positive ion bombardment. This crater grows and with it the intensity of the spot. On examining the geometry of the system, we see that hole *B* plays but a small part, and that *C* acts as pin-hole lens for reproducing the cathode on *D*. This shows that electron beams obey the simple laws of geometrical optics. Campbell Swinton [1] suggested that cathode beams are hollow, with a central pencil down the axis for soft discharge, but did not observe this phenomenon in hard tubes.

If the distances between the diffraction images in Fig. 2 be measured, we find that the triangles formed by the images are nearly isoceles and definitely not equilateral (see Kikuchi [2]). Accurate measurements on various micas are being made.

By using beryllium as a cathode we hope to achieve more constant conditions than with electron metal. After a few hours of discharge the centred ring is formed and should remain fairly constant for a long time. On inserting fused quartz or mica diaphragms in front of the cathode with a hole about 0·2 mm. in diameter, we hope to eliminate the circle and thus obtain the very fine central pencil by itself.

Influence of Light on Paramagnetic Susceptibility

BOSE and Raha have reported [1] that they had observed a diminution of the susceptibility of a chromic chloride solution and of other coloured paramagnetic solutions, when the solutions were exposed to concentrated visible light. They interpreted their result as due to the fact that, by the absorption of light, some of the metallic ions are transferred into excited states, in which they would have a lower magnetic moment than in the basic state. This would indicate that in the case of chromic chloride, one of the three electronic spins had been reversed, with respect to the other spins, in the transition.

Specchia [2] tried to repeat these observations by the capillary ascension method, but came to no definite results. My own preliminary observations, with the aid of a long-periodic torsion balance, confirmed Bose and Raha's observations.

It occurred to me [3] that the explanation given by Bose and Raha would necessitate an extraordinary long life of the ions in the excited states, which had to be at least of the order of 0·1 second. Moreover, the energy which is absorbed will in the end for the greater part be transformed into heat, and the resulting rise of temperature of the substance will, according to Curie's law, also cause a decrease of the susceptibility. One can calculate the influence of this temperature effect for the extreme case when the excited ions have no magnetic moment at all during a time T, if we suppose that the absorbed light of a wave-length of 6000 A. is transformed into heat after the same time T. It appears that for a saturated solution of chromic chloride, in a time so short as 4·5 T, the influence of the temperature effect will already be equal to the effect due to the presence of the excited atoms.

The result of this calculation suggests that the observed change of the susceptibility is entirely due to the rise in temperature.

I have tested this latter hypothesis in the following way: Two equal bulbs, filled with a saturated solution of chromic chloride, were suspended by a torsion wire symmetrically in an inhomogeneous magnetic field, so that the magnetic forces exerted on the bulbs were in equilibrium. The periods of the torsion balances used were rather short: 15 and 30 seconds.

When the light of a high-pressure mercury arc was concentrated on one of the bulbs, a change in the susceptibility could be observed, which increased with the time, and could be interpreted, assuming Curie's law, as due to a rise in temperature of 0·0010° per second. The red and infra-red rays were filtered off by a solution of cupric chloride, and as the arc was calibrated with a flicker photometer, it could be estimated that the energy of the visible light falling on the bulb was sufficient to cause a rise of temperature of about 0·0013° per second. Afterwards the rise of temperature was measured directly in the same arrangement with a thermo-element and proved to be 0·0011° per second, the rise being linear with regard to time during the experiment.

The agreement with the measurements on the change of the susceptibility is satisfactory, and it may be concluded that the effect observed by Bose and Raha really exists, but is very probably due to a rise of the temperature of the substance. No conclusions about magnetic moments in excited states can thus be drawn from such experiments.

I wish to express my thanks to Prof. A. D. Fokker and to Dr. A. C. S. van Heel for the active interest they showed in this research, and to Prof. W. J. de Haas, who kindly put the mercury arc at my disposition.

Infra-Red Bands in the Aurora

IN his letter in these columns [1] regarding the infra-red aurora spectrum observed by Vegard, Jevons failed to say anything about an intensity phenomenon in the first positive bands of nitrogen to which I first directed attention in a note in the *Physical Review*. [2] I called this phenomenon the variation of intensity within a progression, the progression in this case being a 'v'' progression. It is strikingly demonstrated in Lord Rayleigh's [3] experiments on the afterglow in mixtures of nitrogen and the rare gases. In this paper Lord Rayleigh suggested that the auroral radiation of wave-length 6323 A. was probably the first positive nitrogen band (10, 7). In directing attention to Lord Rayleigh's experiments, I pointed out that his results could be interpreted as either real or apparent violations of the Franck-Condon rule for band intensities. Recently, a similar result in iodine, namely, the observations of Ramsauer on the quenching of a fluorescence series in an iodine-oxygen mixture, was explained by Loomis and Fuller, [4] who

suggested that the effect was due to irregular reabsorption of the fluorescent light. The irregularity of the reabsorption was explained by enhanced predissociation in the upper electronic state. A similar explanation could apply just as well to nitrogen, since enhanced predissociation is produced in the upper electronic state of the first positive bands in the presence of rare gases. In both iodine and nitrogen the phenomenon of variation of intensity in a 'v' progression would have to be interpreted as an apparent violation of the Franck-Condon rule.

The connexion between the phenomenon which has been discussed above and the identification of the 7883 radiation in the aurora as the first positive nitrogen band (7, 6) is obvious. If (7, 6) is observed in the aurora, then why are (7, 3), (7, 4), and (7, 5) missing? According to the Franck-Condon rule, these bands should be stronger than (7, 6), and yet they have never been reported in any auroral displays. The 6323 radiation which was identified as the band (10, 7) presents a similar problem. The observation in laboratory experiments of violations of the Franck-Condon rule, be they real or apparent, enable us to identify such bands as 7883 and 6323 as nitrogen bands.

Chain Reactions in Enzymatic Catalysis

I MUST thank Dr. Richter[1] for raising the fascinating problem of whether enzymes act by initiating chain reactions. If this is correct, the value which I calculated[2] for the number of hydrogen peroxide molecules destroyed by a catalase molecule per second, namely, about 10^5, retains its biological significance, but the enzyme surface is far less active than I supposed. The view that oxidative enzymes in general initiate chain reactions was put forward by Haber and Willstätter.[3] I propose to examine this view, but only some of the arguments which I shall bring against it would be valid if catalase were unique among enzymes in starting a chain reaction. This is, however, very unlikely. Peroxidase was shown by Kuhn, Hand, and Florkin[4] to have the same degree of activity per molecule per second, and a very similar active hæmatin grouping.

The chain theory renders the proportionality observed in many cases between enzyme concentration and reaction velocity unintelligible. If the chains end when two free radicals meet, as Haber and Willstätter assume, their length should be shorter the greater the concentration of radicals, and the reaction velocity should be about proportional to the square root of the enzyme concentration, as Allmand and Style[5] found it proportional to the square root of the illumination when hydrogen peroxide was photolysed. If the chains end on the walls or other foreign substances, the velocity should be appreciably reduced by some of the very miscellaneous impurities found in catalase preparations. Zeile and Hellström,[6] among others, found that neither of these conditions was fulfilled in the case of catalase.

Again, the chain theory does not account for specificity. Thus Haber and Willstätter postulate free OH radicals not only in the catalase reaction, but also in the actions of acetaldehyde oxidase and alcohol oxidase. If this were the case, catalase would catalyse the oxidation of acetaldehyde and alcohol by hydrogen peroxide. Similarly, they postulate meriquinoid radicals as links in the chain produced when a dehydrogenase catalyses the reduction of a quinone by a hydrogen donator such as succinic acid. If this were so, dehydrogenases would not be specific, for a meriquinoid radical produced by the dehydrogenation of succinic acid could proceed to remove a hydrogen atom from a different hydrogen donator, for example, glucose or lactic acid.

Finally, the theory does not explain the fundamental fact that most intracellular oxidations do not yield heat directly, but the energy of oxidation is mainly transferred to other molecules. For example, the energy of oxidation in muscle is largely used to resynthesise glycogen from lactic acid. These coupled reactions, involving as they do the interaction of at least four molecules, can only occur at a specific surface where the various reactants are held simultaneously. It is extremely difficult to see how such a reaction could occur in a homogeneous medium, especially when the molecular concentrations of some of the reactants are very low. For example, the oxygen concentration in tissues is less than 10^{-4} M, and it can fall below 10^{-7} M without slowing down bacterial respiration.

For the above and other reasons, I think that the majority of biochemists will demand very strong experimental evidence before they accept the chain theory of enzyme action.

Occurrence of *Bathynella* in England

IN 1927 I happened to visit the well-known Bath Stone Quarries at Corsham, near Bath, for the purpose of collecting *Cyclops* from the underground water of the district.

Looking through the material on my return to Marlborough, I came across two specimens of a small crustacean that I was unable to identify and they were put on one side, as I was working at the time exclusively on the distribution of *Cyclops* and hydrogen ion concentration.

In 1931, quite by accident, I again examined these two specimens, and found them to belong to the very remarkable group, the Syncarida. Both specimens were immature and not well preserved, but they were evidently *Bathynella* or *Parabathynella* and were sent to Dr. W. T. Calman, keeper of zoology at the British Museum (Natural History), who identified them provisionally as *Bathynella chappuisi*, Delachaux.

The Bath Stone Quarries are very extensive, comprising some sixty miles of trolley lines and containing a number of underground wells. In addition, one has to work entirely in the dark except for an electric torch, since the galleries are about 100 feet below the surface, and it seemed as if the rediscovery of these minute animals might be a very long task.

On June 15 of the present year I came across twenty to thirty living specimens and there is reasonable evidence that the piece of water in which they occurred is a remarkably permanent one, so that now, knowing the exact spot, one can go there with a reasonable amount of confidence.

Dr. Calman and Dr. Isabella Gordon have now examined some fresh specimens and are apparently satisfied that the original diagnosis was correct. The species is therefore *Bathynella chappuisi*, Delachaux.

Since no member of the Syncarida has been recorded from the British Isles before, the occurrence of these animals is of more than ordinary interest.

A. G. Lowndes.

Marlborough College,
Wilts.

Mr. Lowndes is to be congratulated on a discovery of exceptional interest. Since *Bathynella* has scarcely yet penetrated into English textbooks of zoology, it may not be superfluous to give a brief summary of its history.

Just half a century ago, Prof. Vejdovsky found in a well in Prague two examples of a minute crustacean which he was unable to refer to any of the recognised groups. Eighteen years later he kindly allowed me to re-examine the surviving type specimen and I was able to point out its resemblances to the Tasmanian *Anaspides*. Another fifteen years had to elapse, however, before the animal was found again, this time in Switzerland by Dr. P. A. Chappuis. A second species was later described from Switzerland by Dr. Th. Delachaux, and has also been recorded from Rumania. It is to this second species that Mr. Lowndes's specimens appear to belong. Since then a related genus, *Parabathynella*, has been described by Chappuis from Serbia, and the gap separating the European Syncarida from their Australian and Tasmanian relatives has been partly bridged by Sars's unexpected discovery of another species referred to *Parabathynella*, from a cave in the Malay Peninsula.

These minute, blind, subterranean crustacea are the degenerate survivors of the Syncarida found as fossils in the Carboniferous rocks of Europe and America, which have disappeared from the surface of the earth, except in Tasmania and Victoria.

No doubt careful search in the subterranean waters of wells and caves would greatly extend the known range of these crustacea, and it is to be hoped that Mr. Lowndes's example will lead cave explorers to turn their attention to the almost unknown cavernicolous fauna in the British Isles.

River Gauging and Flood Prevention

It is with great satisfaction that I have read the leading article on this subject in Nature of July 2 with its complimentary reference to my measurements on the Ness Basin. On this area there are six principal water-level stations at which continuous records are being kept on clock-driven gauges. The measurements of flow, at ordinary flood and low water stages, of the three principal rivers are completed, and all that is now necessary is the maintenance, for all time, of the water-level records—a continuity that no individual can assure. The Caledonian Canal has kept daily water-level records over a great number of years and it is now possible to give with considerable accuracy the flow from Loch Ness during the great floods of the past. If the big water interests of the area will combine to assure the maintenance of my established water-level stations, and to establish other stations when required, there is no problem connected with the use of their water resources which cannot be tackled satisfactorily.

There is no doubt that inland water survey should become a national matter and that it demands a water survey department, such as forms part of the Geological Survey of the United States, which publishes hundreds of papers on systematic investigations of surface water supply.

Local associations or bodies representing the water interests of the areas should be formed to carry out the water-level work and to keep the records. The superintendent of the local association should be under the authority of the national water survey department.

In the article in Nature it is suggested that the new Drainage (or Catchment) Boards should carry out all this survey work; and I agree, provided the water survey work is definitely under the control of a water survey department of the Ministry of Agriculture, because it is necessary to assure that the many arduous duties which will devolve on these Boards will not deflect the course of systematic measurement.

Existing water users have already a mass of useful data; and as these users are invaluable collectors of data, they should be represented in any water survey organisation. This is effected in the United States through the central control of the Geological Survey.

The lead given in Nature should be most helpful in bringing us one step nearer to the much-needed organisation of a water survey of Great Britain. The subject is to be discussed at a joint meeting of Sections A and E at the forthcoming York meeting of the British Association; and it is to be hoped that the result will be the formation of a national body to carry out the survey required.

Scientific Method

The subject of the leading article of Nature of May 28 must commend itself to the earnest consideration of all those who view with consternation the present drift of our civilisation towards chaos. Nothing is more needful than what, for want of a better word, we call the 'scientific' point of view. Nevertheless, experience has shown that the great investigator is seldom well fitted to guide the course of practical affairs; the 'passion for discovery' differs little from other passions in being linked with a certain prejudicial obstinacy. On the other hand, the exposition of the rules and principles of scientific method can be made intelligible only when the intellect has been already hardened by the educational disciplines inseparable from a system the prizes of which are awarded to those with most 'knowledge'—often synonymous with good memory.

There is, I submit, a middle course, namely, in the teaching of the history of scientific ideas. I say, "scientific ideas", since the usual hotch-potch of names and dates is scarcely history and certainly not science. But in the scholarly and critical exposition of such works as Newton's "Opticks", Harvey's "Disquisition", and Boyle's "Sceptical Chymist", in their true historical setting (in the absence of which they appear merely as 'out of date'), illustrated by such experimental methods as were available to these great thinkers, we may show science as a living, growing organism, born of intellectual *struggle*; we may teach the little known truth that theories which have been 'proved' to be 'wrong' have often only been shown to be inadequate.

By some such means we may, I believe, inculcate a just appreciation of the *real* meaning of fact and hypothesis, of cause and law. Incidentally we may both learn and teach caution and modesty, two qualities that do not always characterise the pronouncements of modern science.

Research Items

Mortuary Caves of Szechwan, China.—Relics from the artificial caves of Szechwan Province in western China have been described by the collector, Mr. David C. Graham (*Proc. U.S. Nat. Mus.*, Art. 16, vol. 80). Thousands of these artificial caves are to be found in the sides of the hills and cliffs from Hupeh Province on the east to the highlands of the Szechwan-Tibetan border and along the Yellow River in the province of Kansu. Varying from a few feet to 130 ft. in depth and about six feet high by six feet wide, they are carved from the solid stone, the sides plainly showing chisel marks. Some are so close to one another that holes have been knocked in the dividing walls. It is popularly believed that they are 'barbarian'; but on both historical and archæological grounds it is demonstrable that they do not antedate the Chinese and almost certainly belong to the Han dynasty at about the beginning of the Christian era. The best caves have elaborate carvings above and around the front openings and on the sides and pillars near the entrance. Certain conventional designs in these carvings are also found on Han monuments of various types. A large number of burnt clay figures have been collected from the caves. Glazed figures are rare, but a fragment of a bottle-neck and part of a pottery bell show a green glaze. The figures include the foot of an elephant, dogs, fowls, horses' heads, human figures—among these, servants, actors, a figure playing a flute, etc., in costumes which indicate that little change has taken place in dress down to the present day. The clay vessels show the use of the potter's wheel. The commonest artefact is the earthenware coffin. Many carvings and artefacts reflect customs or represent implements in present use among the Chinese, but not among any primitive tribes.

Archæology of Eastern Colorado.—The second report by Dr. R. B. Renaud, director, on the work of the Archæological Survey of Colorado (published by the Department of Anthropology, University of Denver) describes the field-work carried out during the summer of 1931. It covered the valley of the Upper Arkansas in southern Colorado and the valley of the South Plate River and the territory north of it in the northern part of the State. The ground has now been cleared for preparing a better contact between Colorado and Wyoming and for an approach to western Nebraska, the next field of operation. The total number of sites covered in the present report is 116, of which eleven are double, that is, pictographs are found on both sides of the river or there is a major site on one side and a minor, possibly a look-out, on the other. Camp sites were by far the most frequent, 37 being reported from the South-Platte drainage area, 19 from the Upper Arkansas, and 8 south of Denver. A great many possibly date from the prehistoric period. 19 workshops were found, of which 13 were in the north. The northern area is distinguished by its more abundant camp sites and workshops, its more frequent sites with tipi rings, as well as its more numerous metates and manos. On the other hand, the southern area comprises all the sites with pictographs and stone enclosures, as well as two of the three known rock shelters. There are evidently cultural and geographical differences between the two areas. The collection of artefacts made in 1931 was not extensive; but some large collections in private hands were examined. The same distinction between the culture of the northern and southern areas is to be noted in the distribution of the classified types of implements; while in regard to their material, in both areas that most commonly employed is quartzite, but the place of flint, which comes second in the south, in the north is taken by chalcedony.

Brachial Muscles of Primates.—In a paper on the brachial flexor muscles in primates, A. B. Howell and W. L. Strauss, jr. (*Proc. U.S. Nat. Mus.*, vol. 80, 1-31; 1931), state that these muscles as a whole exhibit no distinct phylogenetic trend; the variations are individual rather than generic. The authors direct attention to the contrasting specialisations of the biceps muscle in the Lorisinæ and the Hylobatidæ. In all other primates this muscle is normally composed of the coracoid and long heads. In the lorises (*Nycticebus*, *Loris*, and *Stenops*) the biceps possesses one head of the long variety, the coracoid head being missing. In the gibbons (Hylobatidæ) the long head is present, but the coracoid head is replaced by one arising from the humerus, and there are most intimate connexions with the surrounding muscles, for example, the pectoralis major and the forearm flexors, which produce a mechanical arrangement well adapted to the extreme mode of brachiation exhibited by the gibbons. This unique anatomical arrangement is clearly an extreme functional adaptation peculiar to the gibbon, and cannot be regarded as representing a stage in the evolution of the biceps of man and the anthropoid apes. While this structure of the gibbon's biceps seems undoubtedly to be adaptive, it is apparently not a necessary outcome of the brachiating mode of locomotion, for such able and constant brachiators as *Ateles*, *Colobus*, *Pan*, and *Pongo* exhibit no trace of such an arrangement.

Deep Sea Collecting.—For three years now the Bermuda Oceanographic Expeditions of the New York Zoological Society under the leadership of Dr. William Beebe have made collections of deep-sea animals in the same region nine and a quarter miles south south-east of Nonsuch Island, Bermuda. That these collections must be becoming very complete as representative of the deep-sea fauna in that area is shown by a recent publication (*Zoologica*, **13**, No. 3), which gives the lists of hauls made during May-November in 1931. Up to the present date, 1350 collections have been made at all depths down to 2000 fathoms in mid-water, the majority being at the surface and between 500 and 1000 fathoms. The fruitfulness of these collections is already shown by two further publications in the same periodical (**13**, Nos. 4 and 5). In the former Dr. Beebe describes nineteen new species of deep-sea fish, and in the latter the same author and John Tee-Van record six new species of shore fish from that region. It is by such continuous collecting that the sparsely distributed members of the pelagic deep-sea fauna will become better known, and we hope that more material will be accumulated; for until the many unknown forms have been fully classified and described the study of their life histories is impossible.

Nuclear Structure.—Prof. Ruggles Gates devoted his presidential address to the Royal Microscopical Society (*J. Roy. Micr. Soc.*, **52**, 1932, pp. 1-19) to a consideration of recent work on nuclear structure. Evidence is accumulating that in plant cells the nucleolus generally contains two substances which may occasionally form separate bodies, and that one of these substances enters into the prophase transformations of the chromosomes, while the other does not. He referred to observations on the chromosome vesicles or karyomeres which show that these become closely appressed in the resting condition of the

chromosomes (for example, in the teleost *Fundulus*), but the delicate vesicle-walls persist and the vesicles do not completely coalesce until after each has formed a chromosome within itself in the prophase. This and other examples afford evidence that each chromosome maintains its morphological peculiarities from one cell generation to another, and confirms the view that the resting nucleus contains the chromosome materials in the same spatial arrangement as in the preceding telophase. Interesting comments are given on the spindle fibres and on cases of polyploidy in certain somatic tissues while the germ cells in the same animals remain diploid. Prof. Gates discussed the internal structure of the chromosomes and their method of division and made reference to mitoses in cells of root tips, which show that the chromosome splitting occurs in one metaphase for the separation which is to take place in the next. In an estimate of the size of genes, Prof. Gates remarked that it would appear probable that they and virus particles are about the same order of size, each containing not more than a few hundred organic molecules, and that it seems likely particles of this size are the smallest in which vital phenomena can be exhibited.

Virus Diseases of Potatoes.—The results of the studies of plant virus diseases financed by the Empire Marketing Board are now being published. The most recent works are to be found in the *Scientific Proceedings of the Royal Dublin Society*, vol. 20 (n.s.), Nos. 15, 18, and 20, May 1932. Paper No. 15 is by Dr. Phyllis Clinch and reports the results of " Cytological Studies of Potato Plants " (pp. 143-172). The green parts of mottled leaves have a structure similar to healthy organs, whilst the yellow areas are distinctly thinner. The peculiar vacuolate inclusions known as X-bodies have been found in the chlorotic areas of leaves infected with crinkle, streak, interveinal, and simple mosaics. They were not seen in aucuba mosaic or leaf roll plants, or on healthy leaves. Their discovery seems to confirm their inclusion in the virus diseases, since the X-bodies are almost exclusively found in this group. Paper 18 is by Dr. P. A. Murphy and is entitled " A Critical Review of some Recent Work on the Occurrence of Virus Complexes in the Potato " (pp. 193-210). The author reviews the literature, which suggests that many virus diseases of the potato are not single diseases but are the results of two or more viruses acting together. Dr. Murphy considers that it would be easier to explain these phenomena by regarding the virus as a chemical substance. Paper 20 is by Dr. P. A. Murphy and Mr. R. McKay. It describes " The Compound Nature of Crinkle and its Production by Means of a Mixture of Viruses " (pp. 227-247). A virus, called 'virus A', has been found to produce symptoms of the disease known as crinkle on the variety Irish Chieftain if the latter was previously infected with simple mosaic. This finding is in accord with the work of Dr. R. N. Salaman of Cambridge, who has separated three constituent viruses from English crinkle.

Age of Monazite from Portland, Conn.—Dr. C. N. Fenner has analysed for uranium, thorium, and lead a crystal of monazite from a pegmatite occurring at Portland, Connecticut (*Amer. J. Sci.*, April 1932). The results may be summarised as follows :

$PbO = 0 \cdot 1086$ per cent	$Pb = 0 \cdot 1007$ per cent
$U_3O_8 = 0 \cdot 00$	$U = 0 \cdot 00$
$ThO_2 = 8 \cdot 52$	$Th = 7 \cdot 489$
$\frac{Pb}{0 \cdot 36 Th} = 0 \cdot 037$.	Age $= 278$ million years.

The age corresponds with the close of the Devonian. Special interest is attached to this result from the fact that the uraninite from the same quarry which was analysed by Hillebrand many years ago has a lead-ratio of $0 \cdot 038$. The check is very gratifying and gives additional support to the essential correctness and reliability of the principles on which the age of radioactive minerals are based. In particular it should be noticed that the agreement depends on the use of the value $0 \cdot 36$ for k (the factor by which Th is multiplied in the formula). With $k = 0 \cdot 25$, as recently advocated by Kirsch, there would be a considerable discrepancy. The value $0 \cdot 36$ is further supported by the concordant results obtained by Fenner from samarskite and monazite from Brazil.

A Fossil Horned Artiodactyl Ungulate from Texas.—Among the fossils recently acquired by the Palæontological Museum of the University of California through the generosity of Miss Annie M. Alexander, is the skull of a remarkable horned artiodactyl from the Pliocene of Texas. It is described by Dr. R. A. Stirton (*Bull. Dept. Geol. Univ. California*, vol. 21, No. 6, 1932), who shows that it represents an extreme development of the four-horned skull of *Protoceras* which was discovered by the late Prof. O. C. Marsh in the Oligocene of South Dakota. *Protoceras* has a pair of frontal horns and a pair of premaxillary horns of moderate size. A somewhat larger animal, *Syndyoceras*, from the Lower Miocene of Nebraska, has the same horns much elongated. The new skull from Texas, which is of still later geological age and is named *Synthetoceras*, is again larger, and has the premaxillary horns relatively enormous and fused together except at their free tips. The succession is thus interesting as showing the same increase in the relative size of the horns which is already known in successive members of other groups of artiodactyls, such as the deer.

Estimation of Ground Water.—In connexion with the important series of reports on ground water supplies in the United States, the Geological Survey of that country has published a pamphlet on " Methods of Estimating Ground-water Supplies " (*Water-Supply Paper* 638-c), which contains a full discussion of the problems involved, with references to the literature of the subject. No one method is applicable to all conditions. Some water-bearing formations function chiefly as reservoirs, others chiefly as conduits, but all of them have some of the properties of both. Some of the methods estimate the intake from surface streams by gauging stations, others estimate the discharge from springs, or the intake may be estimated from rain and melting snow and the discharge by evaporation from the soil or by the transpiration of certain selected plants grown in tanks with measured quantities of water. It would appear, however, that the most trustworthy measurements are obtained by water-stage recorders installed over wells. Water levels in wells are sensitive to every change that takes place in ground water, and these changes can be almost perfectly recorded by an automatic recorder. But all methods are being tried, and great improvements have been effected in recent years.

Spectrum of the Solar Corona.—A paper was read by M. Bernard Lyot on Feb. 19 before the Société Française de Physique, in which he gave an account of the success which has now attended his efforts to study the solar corona at the Pic du Midi at other than eclipse times (*J. Phys.*, 3, 31 S). The main new feature in his work is the great care taken to avoid parasitic light in the optical system ; the other usual source of trouble, diffraction by gross particles in the atmosphere, was not serious. The spectrum of the green line has been obtained on a grating with a dispersion of $1 \cdot 2$ A. per mm., and the red line has been photographed with a prism giving 11 A. per

mm.; the average wave-lengths for these are given as 5302·83 ± 0·03 A. and 6374·75 ± 0·15 A. respectively. One feature of special interest is the breadth of the green line, which extends over 1·3 A. and has an intense core about 0·6 A. wide. These results were obtained at relatively unfavourable times, three or four years after the maximum in solar activity, and show that the methods employed will permit of the study of the red and green lines at any time, whilst it is quite possible that other lines can be obtained at times of greater activity.

The Positive Column.—Two accounts of the positive column which have just appeared, by R. Seeliger (*Physik. Z.*, April 1) and R. Holm (*Z. Phys.*, March 31), emphasise how unsatisfactory our knowledge of the passage of electricity through gases still is, even in the simplest cases. Langmuir has given a very full theory of the uniform positive column, and Schottky and Townsend less complete treatments, but attempts to compare these with experiment, except perhaps in the case of mercury, are limited both by lack of data for such discharge parameters as the temperature of the gas and of data for various atomic properties. Seeliger's article, which deals with monatomic gases, is largely an elaboration of Schottky's diffusion theory. Seeliger accepts the experimental result which lies at the basis of much of Langmuir's work, that the electrons have often a Maxwellian distribution of velocities corresponding to a temperature much in excess of that of the gas, and makes some interesting comments on how this temperature may be maintained. There are, however, special difficulties with the noble gases on account of the frequent occurrence of moving striations and the practical impossibility of finding the concentration of metastable atoms by other than delicate optical methods. Holm discusses diatomic gases, again starting from Schottky's theory, which he shows to be in reasonable agreement with his and Güntherschulze's measurements of the field in the positive column, but makes a distinct break from earlier work in his insistence on the importance of negative molecular ions, the conditions for the formation of which are still little understood.

Astronomical Topics

Comets.—An interesting point has arisen with regard to Newman's comet (1932 *f*). It appears that there are two comets, several minutes of arc apart, that have similar motion. This was first detected by Herr Schmitt, and was announced in a telegram from the I.A.U. Bureau on July 1. It is quite probable that some of the observations supposed to belong to Newman's comet actually belong to the other one. The following orbits of Newman's comet have been computed; the first is by Dr. Whipple and Mr. Cunningham from positions on June 1, 7, and 20 (*Harvard Card* 222), the second by Dr. M. Davidson from observations by Dr. W. H. Steavenson on June 21, 25, and 30:

T	1932 Sept. 27	1932 Sept. 25·01 U.T.	
ω	73° 50′	70° 9′ 16″	1932·0
Ω	244 50	245 7 33	1932·0
i	76 50	78 21 20	1932·0
q	1·57	1·6421	

Three positions are given below; the first is presumed to belong to Newman's comet, the second is the discovery position of Schmitt's comet. Dr. Davidson considers that the third also belongs to Schmitt's comet:

U.T.	R.A. 1932·0.	N. Decl. 1932·0.	Observer.	Place.
June 22·1454	15^h 33^m $44·4^s$	9° 12′ 10″	van Biesbroeck	Yerkes
25·8662	15 28 36	11 45	Schmitt	not stated
July 1·9666	15 16 59·8	15 0 56	Steavenson	Norwood

Schmitt gave the daily motion of his comet as $-1^m 40^s$, N. 35′, which was practically the same as that of Newman; it can scarcely be doubted that these two bodies are portions of a single comet that split into two portions at some date in the past, like Biela's comet; this would make it probable that the period of the comets is not very long. A search through the catalogues has not revealed any comet with similar elements; there is a distant resemblance to 1898 I (Perrine), but that has a period of three or four centuries.

Orbits of Double Stars.—*Circular* No. 86 of the Union Observatory, Johannesburg, contains a determination by Dr. R. T. A. Innes of the orbit of the star Innes 35, the duplicity of which he discovered in 1897; the position is R.A. 6^h $53·7^m$, S. Decl. 35° 22′ (1900). It is a very close binary, the greatest elongation being only 0·3″. It has now completed two revolutions since discovery, and the period is thus known with considerable accuracy. This, as Dr. Innes points out, is a help in finding the other elements; they run as follows; Period 16·5 years, periastron 1926·8, e 0·586, a 0·315″, i 56·3°, 269·7°, 116·4. Applying Eddington's mass-luminosity relationship, Innes finds a parallax of 0·040″, masses of 0·91 and 0·87 of the sun, and absolute magnitudes of 4·8 and 5·0. The apparent magnitudes are 6·8 and 7·0, the spectral type F5. The separation of the stars at periastron is only 0·07″, so that most of the observations are in the region near apastron. Dr. Innes gives a second paper, explaining his method of computing double-star orbits, which makes use of the $X.Y.$ Tables that he published in 1927; he adds a new table that gives the value of arc *minus* sine for various angles.

Norman Lockyer Observatory.—The Council of this Observatory has recently published its report for the year ended on March 31 last; great satisfaction is expressed at the large amount of work carried out by Dr. W. J. S. Lockyer and Mr. Edwards. The former has recently published in the *Monthly Notices of the Royal Astronomical Society* a study of the relation between the corona and the prominences; the latter has made a study of the spectra of stars of type B, and continued the work of deducing spectroscopic parallaxes which has been going on for some years. The collection of stellar spectra photographed at the Observatory now amounts to 6458. The chief event of the year has been the completion of the photographic equatorial presented by Sir Robert Mond (see NATURE, June 4, p. 838); it includes four Zeiss triplet lenses of different diameters, and has an electrically controlled driving clock by Messrs. Cooke, Troughton and Simms. An interesting photograph of a bright meteor passing the Pleiades was obtained with it by Dr. Lockyer on Jan. 11; it is reproduced in *Monthly Notices, R.A.S.* for March, and gives much information as to the changes of brightness exhibited by the meteor in its flight; unfortunately it was not observed visually, so the exact time of its appearance is not known. It will be remembered that Dr. Lockyer photographed another interesting meteor in 1922 (*Monthly Notices, R.A.S.*, vol. 83). The investigations at present in hand include studies of the spectra of ζ Tauri, β Canis Majoris, and 52π Aquarii; also of certain stars with bright hydrogen lines.

Robert Brown and the Cell Theory

THE Linnean Society has issued as an extract from its *Proceedings* (1931–32, pt. 2) the series of addresses delivered at the general meeting on Nov. 19, 1931, which took the form of the centenary celebration of Robert Brown's discovery of the nucleus of the vegetable cell. The brochure contains an account, by Mr. J. Ramsbottom, of Brown's life and botanical work, one by Mr. S. Savage of his connexion with the Linnean Society, the passage from the memoir containing Brown's account of his discovery, and an address, by Lieut.-Col. J. Stephenson on Brown's discovery in relation to the history of the cell theory.

The discovery was announced at the close of a paper "On the Organs and Mode of Fecundation in Orchideæ and Asclepiadeæ" read at the meetings of the Society on Nov. 1 and 15, 1831. The paper was afterwards printed in the Society's *Transactions*.

It was characteristic of Brown to refer incidentally in communications the main purport of which was taxonomic, to discoveries of fundamental importance. In 1809, in a monograph on the Proteaceæ, which he had studied in Australia, he indicates the true relation between endosperm and embryo in the seed. In 1825, to a description of the remarkable Australian Juncaceous tree, *Kingia*, he adds his observations on the structure of the ovule and female flower in the Cycads and Conifers, which established the distinction between the Gymnospermous and Angiospermous flowering plants. To Brown also is owed the recognition of the Brownian movement of small particles (1827), and of the streaming of protoplasm, which latter he observed in the staminal hairs of *Tradescantia* (1831) many years before the 'discovery' of protoplasm.

Brown described the nucleus as a more or less distinctly granular areola, generally somewhat more opaque than the cell membrane, to which it sometimes adheres, projecting into the cell cavity, but it is not infrequently central or nearly so. It was observed in several families of Monocotyledons and Dicotyledons. Brown was the essence of caution, but the remark of Prof. F. E. Weiss, after reading the extract from the memoir, that Brown was inclined to regard the nucleus as an attribute of all vegetable cells, is justifiable.

Lieut.-Col. Stephenson pointed out that in 1831 we have already no inconsiderable part of that body of doctrine that goes by the name of the 'cell theory'. It is incomplete, in that it has scarcely as yet been applied to animals, no account of the origin of cells has been given, and the emphasis is mainly on the cell wall. Between 1831 and 1838, through the activities of the Breslau school under Purkinje and the rival Berlin school led by Joh. Müller, cells had been described in all the chief tissues of the animal body; the production of new cells by division had been seen by Dumortier and other botanists, nucleus and nucleolus had been recognised, and animal and plant cells appreciated as equivalent structures. Purkinje had noted the absence of a special membrane in animal cells.

The cell theory was therefore practically established by the year 1838, and Lieut.-Col. Stephenson protested vigorously against the general use in lectures and textbooks of the phrase "the Cell-Theory of Schleiden and Schwann". He insisted that Schleiden's erroneous theory of endogenous cell formation, accepted by his pupil Schwann, was a distinctly retrograde movement. Schwann also conceived the erroneous idea of the origin of new cells in the intercellular substance; and his mode of comparison of the plant and animal cell tended to accentuate and to perpetuate the view of the cell wall as the chief and distinctive character of the cell. Schwann's "Microscopical Researches" was published in 1839. In 1850, Braun expressed the opinion that the cell was, properly speaking, the substance within the membrane; but it was 1861 before Max Schultze defined a cell simply as a particle of protoplasm containing a nucleus. Therewith Brown may be said finally to have come into his own. Among the builders of the cell theory he holds an honourable place. A. B. R.

The Value of 'Protective' Adaptations of Animals

ONE of the hypotheses on which the theory of natural selection is based consists in the interpretation of the coloration and general appearance of animals from the point of view of protection from enemies. The range of 'protective' devices considered to be sufficiently effective as factors in the selection is very great, but exact investigations aiming at proving that such devices actually protect their possessors are scarce.

Selectionists assume a discrimination in the choice of prey on the part of predators, and one of the methods by which the existence of such a discrimination can be tested obviously consists in studies on the food of predators, by analysing the contents of their stomachs. Results of the studies, however, can only be convincing if the series of records are sufficiently long to eliminate the accidental and to arrive at statistically sound conclusions. In this respect, the investigations on the contents of birds' stomachs undertaken by the U.S. Bureau of Biological Survey* are beyond reproach, for they cover a period of more than forty years (since 1885), during which about 80,000 birds have been examined and as many as 237,399 identifications of animals found in their stomachs made. A common objection to this method is that anything found in a bird's stomach would be in an unrecognisable state. This, however, proved to be a misconception, since most birds swallow their food whole, and even in the cases of the most fragile insects, such as butterflies, certain parts, for example, wing scales, are perfectly well preserved, so that an approximate identification is possible.

The first conclusion arising out of the accumulated data is that the animals serving as food for birds belong to all the systematic groups of the animal kingdom from Protozoa to mammals. Within the size limits, animals of practically every kind accessible to birds are preyed upon, so that no groups can be considered immune from their attacks. Still more significant is the conclusion, supported by abundant statistical data, that the number of captures from each group is in proportion to the abundance of animals of that group. The figures for insects are particularly striking. Records for Rhynchota, for example, constitute about 11 per cent of all records of insects found in the stomachs of birds, and the percentage of known species of Rhynchota in relation to all known insects is about 8 per cent; the respective

* Smithsonian Miscellaneous Collections, vol. 85, No. 7, "Effectiveness in Nature of the so-called Protective Adaptations in the Animal Kingdom, chiefly as illustrated by the Food Habits of Nearctic Birds". By W. L. McAtee. Pp. 201. (Washington, D.C.: Smithsonian Institution, 1932.)

figures for Lepidoptera are 9 and 15 per cent; for Coleoptera, 44 and 46 per cent; for Hymenoptera, 14 and 17 per cent; and so on. This means that various animals are captured by birds approximately in proportion to their numbers, and no selective discrimination between groups on the part of birds is apparent. In other words, the predation takes place in much the same way as if there were no such thing as protective adaptation.

As regards various devices interpreted by selectionists as protective, their value can be gauged by the relative abundance of animals with such devices in birds' stomachs. The data in this respect are very discouraging to selectionists. It is not surprising, of course, that animals with coloration harmonising with their surroundings are eaten freely, since this can be interpreted as the selection in action. Much more important is the fact that animals presumably protected by poisonous secretions are also consumed in proportion to their numbers and, therefore, cannot be said to enjoy any protection. A beetle, *Macrodactylus*, is definitely poisonous and many young birds are killed by eating it, but it is, nevertheless, eaten freely, and the advantage of being poisonous is not obvious. Again, all spiders are venomous, but the 10,000 records of spiders having been eaten by more than 300 species of birds emphasise the complete disregard by birds of this method of protection. All the members of the group of Rhynchota (bugs) are always regarded by selectionists as being specially well protected by their taste or unpleasant smell. The fallacy of this statement is made clear by the 22,395 records of Rhynchota found in stomachs, the percentage of the records being in close agreement with the relative abundance of these insects.

Bright and contrasting colours of insects are usually considered as 'warning', and the Coccinellid beetles, or ladybirds, represent a classical example of 'warning coloration', possibly developed by selection and serving to advertise their unpalatability. There are, however, 1455 records of Coccinellids found in the stomachs of 127 species of birds; since up to 15 insects have been found in one stomach, their 'warning' coloration and the inedibility must be a fiction. Another equally well-known example of a specially protected group of insects is represented by the ants, and their immunity from attacks is said to be so great that many other arthropods secure protection from enemies by mimicking ants. The 12,000 records of ants eaten by well over 300 species of birds make the status of ants as a protected group untenable. Some birds eat ants in very large numbers, and up to 2000 ants have been found in one stomach. It is particularly noteworthy that even ants of the family Myrmicidæ, notorious for their stinging habit, are not avoided, as is shown by 1200 records of their presence in stomachs, containing in some cases up to 400 individuals. Wasps are considered also as regular models for mimicry, being themselves presumably well protected by sting and also 'warningly' coloured, but 140 species of birds eat them, up to 30 wasps at a meal.

The whole book is full of examples of this kind, most carefully collected and thoroughly analysed, and represents an array of arguments of which selectionists will find it very difficult to dispose. The principle of proportional predation is exhibited so clearly and forcefully that a discrimination in the choice of prey by birds (and other vertebrates, also considered in the paper) is shown to be simply non-existent. Indeed, the data at hand denote a complete indiscrimination, the very antithesis of selection, and the phenomena classed by theorists as protective adaptations are shown to bear no relation to the survival of the fittest.

B. P. U.

Aluminium in Foodstuffs

THE meeting of the Society of Public Analysts on June 1 was devoted to papers on the effects and estimation of aluminium in foodstuff.

A survey of the physiological effects of aluminium was given by Dr. J. H. Burn. He said that the first extensive investigation of the physiological effects of aluminium salts was made in 1886 by Siem, working under Prof. H. H. Meyer. Siem found that doses corresponding with 30-40 grains of alumina for a man had no effect whatever when administered by mouth to cats daily for four weeks. When the aluminium salt was injected under the skin, the fatal dose varied from 0·25 to 0·30 gm. of alumina per kilogram. These results, indicating that aluminium has some toxicity when injected, but is harmless by mouth, have in substance been confirmed by many subsequent workers.

Siebert and Wells examined the pathological changes produced by injecting alum and aluminium chloride; they found that anæmia was manifested after nine or ten daily injections, a fall in the hæmoglobin percentage and in the red cell count being recorded. In the spleen, pigmentation, thrombosis, and fibrosis were observed.

The experiments of McCollum and his colleagues, and those of Myers and Mull, show conclusively that the addition of aluminium salts to the diet of young rats has no ill effect on growth, health, and reproduction, even when four successive generations are observed. The experiments of Myers and Morrison, and of Underhill and Peterman, show that when aluminium compounds are given by mouth to dogs, only insignificant changes in the amounts of aluminium in different tissues are found. It follows that aluminium salts are not absorbed from the alimentary tract, except in traces.

As a result of a scare in the United States that the use of aluminium baking powders was dangerous to health, the Department of Agriculture instituted a board of inquiry. The report, published in 1914, described experiments on twenty-six university students carried out in three different universities, who were given amounts of alum varying from 0·2 gm. to 10 gm. daily for about six months. It was unanimously reported from the results of these experiments that the amounts of alum likely to be consumed as a result of alum in baking powder, estimated as up to 1·16 grain of aluminium per person per day, are much too small to have any ill effect. The amounts of aluminium which arise from aluminium vessels were estimated from analyses carried out by Massatch to be about 0·1 grain per person daily.

Indeed, the possible dangers arising from aluminium utensils have been very thoroughly investigated by many workers, on many species of animals; they have also been investigated with equal thoroughness on man. These dangers are non-existent. Clinical reports that symptoms of abdominal pain are relieved by discontinuing the use of aluminium can be ascribed to psychological effects.

Dr. L. H. Lampitt and Mr. N. D. Sylvester outlined a method for the accurate determination of small amounts of aluminium in foodstuffs, in which the Aurin tricarboxylic acid lake is formed under standardised conditions, the red colour of the final solution being measured in the Lovibond tintometer. Separation of aluminium from the 'wet ash' of the foodstuff is effected by a preliminary precipitation

with ammonia, the aluminium being obtained in alkaline solution. Other metals which are liable to be present have been proved not to interfere. The actual determination is carried out on an aliquot portion containing 0·01-0·06 mgm. of aluminium. Using 20 gm. of sample, so little as 0·2 part per million of aluminium can be determined.

The results obtained indicate that the aluminium content of foodstuffs is increased by only a few parts per million after cooking in aluminium utensils. For example, the aluminium content of milk was increased from 0·4 to 0·6 part per million after boiling in an aluminium saucepan, and to 2·5 parts per million after standing overnight. Apples before cooking contained 2 parts per million of aluminium, and after boiling in an aluminium vessel for thirty minutes with sugar and water they contained 14 parts.

Mr. P. L. Bilham described a spectrographic method for the determination of small quantities of aluminium. The aluminium of a biological material is concentrated on to a special electrode. The spectrum is then excited by a condensed spark discharge, modified to remove air-lines as much as possible, and a quartz spectrograph is employed to photograph the spectrum. The plate is developed under standard conditions and then compared with sets of standards on plates prepared under precisely similar conditions. The results show that aluminium is detectable down to 0·01 mgm., and that the intensities of the lines at 3944 A. and 3961·5 A. can be used to judge the amount present up to 0·2 mgm. The method is, of course, specific for aluminium and of a reasonable accuracy.

Carnegie Grants for Libraries and Museums

THE eighteenth annual report of the Carnegie United Kingdom Trust, for the year ended Dec. 31, 1931, has recently been issued.* The opening paragraphs reflect the influences of the financial position of the country upon policy, inasmuch as the main object of the trustees in the immediate future will be one of consolidation rather than the inauguration of new and pioneer schemes. In their view, the urgent demand for drastic economy in national and local expenditure, coupled with the restriction of private generosity, compels limitations of policy. Grants from the Trust will be made in order to maintain and stabilise activities which have already been assisted and have themselves tended to move forward under their own momentum. But grants for entirely new purposes are to be few in number, and to be made only for exceptionally strong and urgent reasons. These decisions, however prudent, must inevitably bring disappointment in various quarters, but, at any rate, they cannot fail to be understood.

Though most people are aware how wide the net is cast, it may be useful and opportune at this juncture of affairs to recall some of the more important schemes which have received allocation of revenue. Outstanding among these is the acquisition of freehold property in Bloomsbury, intended to form the headquarters of the National Central Library and of the Library Association, in an area contiguous to and ultimately destined for occupation by the new buildings of the University of London. The total sum contemplated for this undertaking is large, amounting in fact to about £60,000. It is believed that the two institutions, housed as neighbours, will play an essential part in completing the unification of the nation's library service. For the first time in its history the Library Association will be in possession of premises of its own, large enough for practical operations, and consistent with its dignity as a national body established by Royal Charter. It is hoped that the quarters will be ready within about eighteen months. Complementary in interest is the information that the trustees are still prepared to receive applications on behalf of municipal libraries serving populations between 10,000 and 70,000. Aid is given for book-purchase only, and will be made to such authorities as are prepared to carry out, as fully as financial conditions permit, the main principles of approved modern practice.

Substantial grants have been allotted to various research associations and societies—among these we note British Non-Ferrous Metals, Wool Industries, Linen Industry, British Rubber Manufacturers, British Flour Millers, London School of Economics, Entomological Society, Society for Psychical Research. Rural and Social Service includes schemes affecting community centres, boys' and girls' clubs, youth hostels, and village halls. Enterprises relating to activities in the departments of music and drama have received attention ; while the sympathy and support extended to rural preservation schemes and playing fields is a record of much interest.

The trustees' 'museum policy', initiated rather more than two years ago, is still in the experimental stage, and there may be a temporary period of inaction. Thirteen centres had accepted or been offered grants up to the end of 1931 for reconstruction purposes. These grants are conditional upon the adoption of a scheme prepared by an expert appointed by a joint committee of the Trust and the Museums Association. The substitution of modern cases, the disposal of miscellaneous and irrelevant material, adequate display and labelling, coupled with the adoption of a progressive policy on the lines recommended in Sir Henry Miers's report, are essential considerations.

Finally, the remarkable development of county libraries, closely fostered by the Library Association, established in local areas, demands a few words. Throughout Britain generally the story is one of judicious expansion. At the end of the year 1930–31, some sixteen millions of the population of the United Kingdom were served through 14,000 library centres, almost all of which were administered by voluntary librarians and enlisted voluntary helpers. In no other country as yet could it be stated that any village librarian, in addition to his periodic supply of anything from 50 to 2000 books, can obtain for borrowers access not only to the county stock of, say, 50,000-150,000 volumes, but also through the county headquarters to nearly 5,000,000 volumes held or procurable by the National Central Library, and that, as a rule, special books may be sent by post for private study.

* The Carnegie United Kingdom Trust. Eighteenth Annual Report (for the year ending December 31, 1931), approved by the Trustees on March 11, 1932. Pp. ii+95+4 plates. (Dunfermline.)

University and Educational Intelligence

CAMBRIDGE.—The governing body of King's College, having made provision for four additional fellowships open for competition to graduate members and research students of the University, is offering a fellowship to be associated with the name of the late Mr. E. B. Stringer. Candidates must be members of the University, less than thirty years of age on March 1, 1933, who have worked in (i) chemistry, (ii) experimental physics, or (iii) the chemistry or physiology of plant or animal life. Applications should reach the Provost by Nov. 1.

DUBLIN.—At a meeting of the Senate of the University of Dublin, Trinity College, on June 29,

honorary degrees were conferred upon the following, among others: *M. Eng.*—Prof. F. S. Rishworth, professor of civil engineering in University College, Galway. *D.Sc.*—Prof. R. G. Harrison, professor of biology in the Yale University; and Prof. T. M. Lowry, professor of physical chemistry in the University of Cambridge. *LL.D.*—Prof. W. R. Scott, Adam Smith professor of political economy in the University of Glasgow.

EDINBURGH.—At the graduation ceremonial on June 30 the honorary degree of Doctor of Laws was conferred upon the following, among others; Prof. C. V. Boys, Mr. H. M. Cadell; Mr. D. M. Greig, conservator of Museum, Royal College of Surgeons, Edinburgh; Dr. R. S. MacDougall, formerly reader and Steven lecturer in agriculture and forest entomology in the University; Mr. Andrew Mellon, United States ambassador; Prof. A. Robinson, emeritus professor of anatomy in the University; Sir Archibald Sinclair, Secretary of State for Scotland; and Sir Josiah Stamp.

The following were admitted to the degree of Doctor of Science, titles of theses appearing after the names: Mr. S. C. Devadatta, "The Distribution of Lactate between the Corpuscles and the Plasma in Blood"; Dr. Honor B. Fell, "Morphological and Experimental Studies on the Skeletogenesis of the Fowl"; Mr. D. Finlayson, "Some Physical Problems associated with the Internal Combustion Engine"; Mr. D. S. MacLagan, "An Ecological Study of the 'Lucerne Flea' (*Smynthurus viridis*, Linn.)"; Dr. D. Meksyn, "Electromagnetic Phenomena in the General Theory of Relativity"; Mr. H. S. Ruse, "Theorems in the Tensor Calculus"; Dr. R. H. Slater, "Synthesis of Quinoline Compounds of possible Therapeutic Value".

At the close of the ceremony, the Principal, Sir Thomas Holland, referred to two medallions by Emeritus Professor Schlapp, representing Sir Walter Scott and Thomas Carlyle as students, which have been placed in the McEwan Hall. Walter Scott matriculated in the University in 1783, attended classes for three years but failed in Greek, and his father took him away to his own business. Scott returned in 1789, studied in the Faculty of Law and was admitted to the Faculty of Advocates in 1792. At the age of fourteen years, in 1809, Thomas Carlyle trudged from Ecclefechan to the University of Edinburgh. He seemed to have profited mainly from the teaching of the professor of mathematics, and later in life, just after he had failed to persuade any publisher to accept "Sartor Resartus", he made an unsuccessful attempt to obtain the professorship of astronomy in the University. He was rejected, and that incident probably turned him finally to letters.

LONDON.—The following doctorates have been conferred: D.Sc. in anthropology on Dr. E. J. Dingwall (University College) for two works entitled "Male Infibulation" and "Artificial Cranial Deformation" (Bale, Sons, and Danielsson, 1931); D.Sc. in chemistry on Mr. J. W. Smith (University College) for a thesis entitled "Studies in Intensive Drying and Related Phenomena" (*J. Chem. Soc.*, 1929 and 1931; *Phil. Mag.*, 1929); D.Sc. (Engineering) on Mr. H. C. H. Townend (Northampton Polytechnic Institute) for ten contributions to the study of aerodynamics.

ST. ANDREWS.—Amongst those who received the honorary degree of LL.D. at the graduation ceremonial on June 28 were Sir James Frazer, author of "The Golden Bough", Dr. Albert Schweizer, and Prof. L. R. Sutherland, emeritus professor of pathology in the University.

Calendar of Geographical Exploration

July 11, 1616.—Samuel de Champlain

Samuel de Champlain, the great French explorer, returned to Quebec, which he had founded in July 1608, after his third and greatest journey. He set out in 1615 and, travelling down the Ottawa and Mattawa Rivers, Lake Nipissing, and French River, reached Georgian Bay. Thence he proceeded inland and explored Lake Ontario. Champlain's earliest voyages were to the West Indies and Mexico. In 1603 he travelled up the St. Lawrence, and in the following years surveyed the coasts of Nova Scotia, the Bay of Fundy, and the mainland so far as Cape Cod. In 1613 he reached Allumette Island in the Ottawa River, in an endeavour to discover a supposed short route to the ocean via the Ottawa River. Lakes Champlain, Nipissing, and Simcoe were discovered by him, and he made further journeys on Lakes Huron and Ontario, which had been visited a few years earlier by Brulé. Interestingly enough, Champlain contemplated, during a visit to Panama, the project of a ship canal across the isthmus.

July 11, 1897.—First Air Attempt on the North Pole

S. A. Andrée, a Swedish aeronaut, with two companions and about five tons of supplies, set out in a balloon for the north pole. Heavy guide-ropes dragging over the ice were to be used for steering. Andrée had already made successful flights in this way. Rising from Danes Island, Spitsbergen, at 2.30 P.M., the balloon passed out of sight within an hour. A buoy containing a message that at 10 P.M. the balloon was in 82° N., 25° E., moving towards the north-east at an altitude of 800 ft., was found. But until Aug. 22, 1930, nothing more was known of the fate of Andrée and his companions. On that date, members of an expedition to White Island found their bodies and their diaries. They had reached 82° 56′ N., but had been compelled to return on foot, and had died at Gilos Land, White Island, to the east of Spitsbergen.

July 13, 1102.—An Early Pilgrimage to Jerusalem

Saewulf, or Saewlf, an Anglo-Saxon native of Worcester, a merchant, took ship at the little harbour of Monopoli, near Bari, for his pilgrimage to the Holy Land. The effect of the Crusades was to encourage such pilgrimages, and Saewulf, though not the first to make the journey, was the first who left a narrative of it. His outward journey was made direct from Italy to the Ionian Islands, from Negropont to Rhodes, and thence to Palestine. His record shows the great increase of European influence in the Levant in war, commerce, and pilgrimage; his account of the destruction of pilgrim and trading vessels in Jaffa during a great storm is specially valuable from this point of view. His description of the sites of Hebron is detailed and interesting. Among other places, he visited Nazareth and Cana of Galilee. He embarked on his return journey at Joppa, coasted down past Tyre, Sidon, and Acre, touched at Cyprus, and put in at Rhodes. There he changed to a smaller vessel and later to another, and proceeded through the Dardanelles. The narrative breaks off abruptly at the point when Saewulf was near Constantinople and wished to worship there before returning home. Inevitably, many of Saewulf's historical explanations seem quaint to modern students, but his narrative throws a good deal of light on conditions in his time.

July 13, 1909.—Mikkelsen's Voyages

Ejmar Mikkelsen left Thorshavn in the *Hekla*, in command of an expedition to explore north-east Greenland. Mikkelsen had, with Amdrup, explored

the east coast of Greenland in 1900, worked with the Baldwin-Ziegler 1901–2 expedition in Franz Josef Land, carried out oceanographical survey in the North Atlantic in 1903–4, and, in joint command with Leffingwell, explored northern Alaska in 1906–8. In 1908–10 Mikkelsen discovered the records left by Mylius-Erichsen of his tragic journey of 1907.

July 13, 1923.—American Scientific Expeditions to Mongolia

George Olsen, a member of one of the above expeditions, found the first complete dinosaur eggs. The theory that Central Asia must have been a centre of origin for ancestral types of mammalian life aroused the interest of Prof. Henry Fairfield Osborn, president of the American Museum of Natural History, and eventually led to the organisation of a series of remarkably well equipped scientific explorations of the region of Mongolia which lies between the Kalgan and the Altai Mountains. Palæontology, geology, palæobotany, archæology, topography, zoology, and photography were all represented in the 1925 expedition. But palæontology took first place in the 1922–23 expedition, which justified the theory in such a remarkable way. Dr. R. C. Andrews, the leader of the expeditions, reports that the major geographical features of the Gobi have been determined, and a surveyed line of more than 1000 miles has been run north-west through the heart of the desert.

July 15, 1836.—Sir T. Livingstone Mitchell in Australia

Sir T. L. Mitchell discovered the Grampian Hills, on a journey in Australia during which he also discovered the Wimmera and Glenelg Rivers and cleared up the main features of the Murray-Darling basin east and south of the Darling. Mitchell's explorations in Australia began in 1831, and to him and Sturt is due the elucidation of the drainage system of south-eastern Australia. In 1846 he crossed the Carnarvon Range and discovered the upper portion of the Barcoo River.

July 15, 1874.—The Road to Lhasa

The famous Indian explorer, Nain Singh, left Leh on a journey through western Tibet to Lhasa and the region south of that city. He travelled 1319 miles, of which about 1200 were across country never previously explored, and made detailed surveys of the route. Numerous lakes were discovered, as was the existence of a vast snowy range parallel to and north of the Brahmaputra River. Of this range, Nain Singh recorded the position of several peaks and estimated their heights. Nain Singh on his previous memorable journey had made a route survey of the road between Katmandu and Tradom and of the great Tibetan road from Lhasa to Gartok. He had traced much of the upper course of the Brahmaputra, and made estimates of the heights of various mountain peaks.

July 16, 1906.—Sven Hedin in Central Asia

Sven Hedin, the famous Swedish explorer, started from Srinagar on his journey to the region lying between Shigatse and Leh, and north of the Brahmaputra. He discovered a range of mountains lying parallel to the Himalayas on the Tibetan side, and mapped this previously unknown region. In 1893–97, Hedin crossed the desert between the Yarkand and Khotan Rivers, discovered the buried cities of the Takla Makan, and found that Lob Nor had changed since Przhvalsky visited it. In 1899–1902 he surveyed the Yarkand River and much of northern Tibet. Apart from his archæological work, Hedin made great contributions to the mapping of central Asia, and especially of the sources of the Sutlej and Brahmaputra.

Societies and Academies

LONDON

Royal Society, June 30.—J. W. Cook, I. Hieger, E. L. Kennaway, and W. V. Mayneord: The production of cancer by pure hydrocarbons (1). Tests for cancer-producing action on mice are in progress, or have been completed, with preparations of the following polycyclic aromatic hydrocarbons composed entirely of benzene rings:—(1) All the six possible four-ring compounds, (2) all the ten known compounds out of the fifteen possible five-ring compounds, (3) some compounds containing six and eight rings, and others. Some of the hydrocarbons examined are of very low solubility, and hence all tests carried out with them are unsatisfactory. No hydrocarbon in the pure state has produced cancers except 1 : 2 : 5 : 6-dibenzanthracene and some closely related compounds. It produced cancer of the skin when applied in a concentration of 0·003 per cent in benzene.—**J. W. Cook**: The production of cancer by pure hydrocarbons (2). Preliminary results suggest that 6-*iso*-propyl-1 : 2-benzanthracene is carcinogenic, and a pure sample of this has been synthesised and is being examined for carcinogenic activity, together with other *iso*-propyl and methyl derivatives of 1 : 2-benzanthracene. 5 : 6-*cyclo*penteno-1 : 2-benzanthracene produced metastases in the axillary glands and lungs in four mice to which it was applied. There is evidence that a molecular structure consisting of new rings attached to the 1 : 2- and 5 : 6- positions of the anthracene ring system is particularly efficacious in promoting carcinogenic activity.—**G. H. Eagles and A. H. H. Kordi**: The cultivation of vaccinia virus: a new series of subcultures in cell-free medium. The cell-free medium has been prepared with the view of obtaining from adult rabbit kidney an extract rich in cell substance while eliminating the presence of actual cells. The medium must be freshly prepared. Vaccinia virus has been propagated in this medium through ten subcultures in one series, representing a multiplication of 10^{30} times the original culture with a dilution of 10^{17} of the virus content of the original culture. Though greater irregularity in growth occurs in cell-free medium than in medium containing living cells, experience has shown that with the former substantial yields of virus have been realised.

Physical Society, May 20.—A. O. Rankine: (1) On the representation and calculation of the results of gravity surveys with torsion balances. An alternative method of indicating the functions of the Eötvös torsion balance, and of calculating those quantities, depending upon the distortion of the earth's gravitational field which the balance measures, is described and a convenient method is indicated of applying graphically the necessary corrections for the effects of the earth's rotation and irregularity of the surface of the ground. —(2) Some observations with a gravity-gradiometer. An account is given of a series of observations with a Shaw and Lancaster-Jones gravity-gradiometer, during which it was discovered that very persistent, although small, electric charges could be developed on the mica ring forming part of the oscillation-damping system. Such charges, which may persist for weeks, may not arouse suspicion, although in fact they lead to spurious results in the normal use of the instrument.—**R. L. Smith-Rose and J. S. McPetrie**: The propagation along the earth of radio waves on a wave-length of 1·6 metres. A description is given of the simple transmitting and receiving apparatus which has been employed for the experiments on this wave-length. Measurements of the field-intensity at different distances from the transmitter have been carried out

for various heights of the apparatus above the ground level. When both transmitter and receiver are used very close to the ground, the attenuation curve obtained is similar to that encountered at longer wave-lengths. When, however, the apparatus is elevated by an amount comparable with, or greater than, the wave-length, the field-intensity distance curves have maximum and minimum values, the positions of which depend upon the actual heights employed. These maxima and minima are due to interference between waves transmitted directly from the transmitter to the receiver and those which arrive at the receiver after reflection from the earth's surface.—**Allan Ferguson** and **S. J. Kennedy**: Notes on surface tension measurement. This paper deals with a method for the accurate determination of the surface tension of liquids available in volumes of not more than one or two cubic millimetres. The method described does not involve any knowledge of the density of the liquid. A series of measurements of the variation with concentration of the surface tension of aqueous solutions of *p*-toluidine are also described. Here, also, the method employed is independent of a knowledge of the density of the solution.—**D. K. McCleery**: The fall of potential in a charged insulated cable. The expansion theorem of Heaviside is applied to the solution of the problem in which a cable, having been charged until it reaches its steady state, is insulated at the sending-end, and the potential is required at any point and at any time after insulation. At the sending-end there is an initial steep fall of potential which is due to a part of the charge being drained away from this end, in order to equalise the potential throughout the line when the exciting source has been removed. After the potential has become uniformly distributed, it falls with time according to a simple exponential law.

DUBLIN

Royal Irish Academy, May 23.—**Joseph Algar, Anne E. O'Reilly,** and **Mary Joy**: Some derivatives of dicoumarin. When diacetoresorcinol is heated for five hours with acetic anhydride and the sodium salt of phenylacetic acid, a good yield of α-α′-diphenyl-β-β′-dimethyl-dicoumarin, m.p. 276°-277° C., is obtained. By employing the sodium salts of substituted phenylacetic acids a number of dicoumarin derivatives may be prepared, the yields being satisfactory in most cases.—**Joseph Algar, Vincent C. Barry,** and **Tadhg F. Twomey**: Derivatives of benzo-difurfurane. The condensation of bromacetic ester with diacetoresorcinol gives the diethyl ester of diacetoresorcinoldiacetic acid (m.p. 130°-131° C.), which on hydrolysis affords the corresponding acid (m.p. 264°-266° C.). The latter is converted into β-β′-dimethyl-benzo-difurfurane (m.p. 107°-108° C.) by heating with acetic anhydride and sodium acetate. Various derivatives were obtained.

PARIS

Academy of Sciences, May 23 (vol. 194, pp. 1769-1868).—**L. Cayeux**: The condition and diffusion of phosphoric acid in old sedimentary formations. Consequences.—**Charles Achard, Mlle. Jeanne Lévy,** and **Fernand Gallais**: Experimental researches on some colloidal modifications produced in the blood serum by the injection of concentrated serum and by plasmatic bleedings.—**Armand de Gramont** and **Daniel Beretzki**: The temperature of a piezo-electric crystal as a function of its vibratory regime.—**Georges Claude**: The extraction of the dissolved gases in the Claude-Boucherot method.—**Maurice Fréchet**: Remarks on the probabilities of events in sequence.—**T. Wazewski**: The stability of the integrals of a system of differential equations.—**Alex. Froda**: Measurability in support of functions of real variables.—**G. Valiron**: Some consequences of Ahlfors' theorems.—**M. Delfosse** and **R. Swyngedauw**: The measurement of the friction couple of an axle in its bearing.—**M. Mendes**: The application of the method of variation of constants to the problem of *n* bodies with variable masses.—**V. Smirnoff** and **S. Soboleff**: Some problems of elastic vibrations.—**Mlle. Jacqueline Hadamard**: Perfecting a high precision Nernst bridge.—**Maurice Fallot**: The atomic moments and Curie points of ferro-silicon. Superstructures.—**Pierre Lacroute**: The method of using a large Rowland grating and the study of its faults.—**R. Lucas** and **Mlle. D. Biquard**: The influence of solvents and of temperature on the rotatory powers and dispersions of active bodies.—**Marcel Cau**: The rôle of multiple reflections in the magneto-optic Kerr effects of thin layers of iron.—**M. Chatelet**: Some organic solutions of iodine. Studies of the absorption spectra of iodine in some mixtures of solvents.—**Trajan D. Gheorghiu**: The influence of diffused light on photoelectric measurements.—**G. Mano**: The slowing down of the α-rays in air and Bethe's theory.—**P.** and **M. Lecomte du Noüy**: Studies on the critical temperature of serum. The absorption spectrum of horse serum in the ultra-violet. A curve is given showing the changes in the ultra-violet absorption spectrum produced by heating to 55° C. and 65° C.—**Mme. L. Walter-Lévy**: Contribution to the study of the system MgO, CO_2, H_2O at the temperature of 100° C.—**E. Vellinger**: Contribution to the study of dissociation phenomena in organic media.—**Jean Cournot** and **Marcel Chaussain**: The determination of the loss of weight in corrosion tests. The usual method of cleaning the test specimen by brushing, washing, and drying is shown to be inexact; two alternative methods are described.—**Neda Marinesco**: The action of an oscillating piezo-quartz on sols and suspensions. The ultra-sonic thixotropism of gels.—**Lucien Semichon** and **Michel Flanzy**: The application of chromic oxidation to some mono-acids. Detailed study of the oxidation of volatile fatty acids, and of hydroxy and ketonic acids.—**G. Vassiliadès** and **L. Capatos**: The action of diethylamine on methyl acetylene-dicarboxylate.—**Charles Dufraisse** and **Maurice Loury**: Researches on the dissociable organic oxides. The isomerism of the dimethylrubrenes and the constitution of the rubrenes.—**P. Carré**: The relative mobilities of the radicals in the chlorides of acid alkyl sulphites (R.O.SO.Cl). From a study of the temperatures at which these chlorides decompose in the presence of pyridine, the comparative mobilities of the radicals has been obtained. The mobility of the aryl groups is lower than that of the alkyl groups.—**Ch. Courtot, M. Chaix,** and **J. Kelner**: The mechanism of the action of sodium amide on diphenylsulphinone.—**Louis Meunier** and **M. Gonfard**: The analysis and some properties of the benzylcelluloses.—**J. Duclaux** and **M. Hugon**: The transparency of the pure atmosphere. A study of the limiting distance of vision as a function of the wave-length.—**P. Chofardet**: The transparency of the air. A statistical study of the results of nineteen years' observations on the visibility of Mount Blanc from two stations (Chailluz, Montfaucon).—**Paul Corsin** and **Georges Dubois**: The characters of the Dinantian culm-flora of Champenay in the upper valley of the Bruche.—**A. N. J. Heyn**: Researches on the plasticity of cellular membranes and the growth of plants.—**W. A. Becker**: Experimental researches on cytokinesis and the formation of the cellular plate in the living cell.—**Louis Gallien**: Neotenic reproduction in *Polystomum integerrimum*.—**Mlle. S. Firley** and **M. Fontaine**: The proportion of proteins in the serum of the eel and its variations in the course of changes in salinity.

—**Ph. Lasseur, A. Dupaix,** and **L. Georges** : Remarks on the Boas phenomenon.—**Georges Deflandre** : The Archæmondaceæ, a new family of marine fossil protists with siliceous covering.—**G. Delamare** and **C. Gatti** : Spirochetes and intraleucocytary annular bodies.—**J. Lignières** : *The variability of the pathogenic and* immunising quality of the aphthous virus.—**S. Nicolau** and **Mme. L. Kopciowska** : The elective zone for the Negri bodies in rabbits dying of experimental hydrophobia with fixed virus.

WASHINGTON, D.C.

National Academy of Sciences (*Proc.*, vol. 18, No. 3, March 15).—**A. Einstein** and **W. de Sitter** : On the relation between the expansion and the mean density of the universe. The density derived on the assumption of zero curvature is of the right order of magnitude.—**Marston T. Bogert** and **David Davidson** : Azo derivatives of the pyrimidines.—**L. F. Randolph** : Some effects of high temperature on polyploidy and other variations in maize. The ear-shoot region was enclosed in a wire mesh cylinder and heated by an electrical heating pad to 38°-45° C. for a period of an hour at a time during the 48 hours beginning 27-30 hours after fertilisation. Among the effects observed were the doubling of entire chromosome sets, chromosomal deficiencies and translocations, direct morphological effects such as defective seedlings, and various deviations from the normal fertilisation process. It is suggested that since organisms in Nature are subjected to even higher temperatures than those used in the experiments, high temperatures may have played an important part in the natural production of variations.—**Henry Margenau** : Note on the quantum dynamical correction of the equation of state. A correction.—**W. G. Penney** : Effect of nuclear spin on the radiation excited by electron impact. No theory of polarisation of radiation excited by this means can be complete without taking into account nuclear spin. Calculations for mercury λ2537 give results not in agreement with the experimental data available ; the first order cross-section and approximate wave functions are not sufficiently accurate.—**E. H. Kennard** : Entropy, reversible processes, and thermo-couples. A discussion, with two examples, suggesting that the usual statement to the effect that a reversible process never changes the entropy of the universe is valid only when the process can be isolated completely from all other processes.—**P. W. Bridgman** : Comments on the note by E. H. Kennard on "Entropy, reversible processes, and thermo-couples".—**Francis D. Murnaghan** : On the field of values of a square matrix.—**Aurel Wintner** : Remarks on the ergodic theorem of Birkhoff.—**E. B. Stouffer** : A geometrical determination of the canonical quadric of Wilczynski.—**B. O. Koopman** and **J. v. Neumann** : Dynamical systems of continuous spectra.—**J. v. Neumann** : Physical applications of the ergodic hypothesis.—**Edward Kasner** : Complex geometry and relativity : theory of the 'rac' curvature. Rac curvature or 'rac' for a given curve is defined as the limiting ratio of arc to chord. For ordinary real curves rac equals unity, but for certain imaginary curves it has other values, the chief of which is $\frac{4}{3}\sqrt{2}$. In space of more than two dimensions, curves can be constructed such that it has any assigned value. In general, the rac curvature changes discontinuously if the point moves continuously along the curve or the curve is varied continuously.—**Hassler Whitney** : Regular families of curves (1).—**G. D. Birkhoff** and **B. O. Koopman** : Recent contributions to the ergodic theory.—**J. Shohat** and **J. Sherman** : On the numerators of the continued fraction

CONTENTS

Scientific Leadership in Industry

IN the absence of adequate leadership, science, whether in its broadest aspect or in its narrow technical sense, will never occupy its rightful place in industry. Industry in Great Britain has suffered too much in the past from administrators whose deficiency in regard to a scientific outlook has rendered them incapable of maintaining an adequate scientific staff or of accepting an adequate and sustained research programme as a fixed charge comparable with insurance, depreciation or obsolescence, and incorporating its results in industrial practice.

Not the least important part of the plan which science could evolve would be the provision made for training administrators and leaders for industry and for the State, who would be capable of assessing those scientific factors which are involved to-day in almost every industrial, political or social question of the first importance. Under modern conditions, technical and scientific training is a *sine qua non* of competent leadership whether in industry or in the State, and the absence of adequate planning on scientific lines to-day is largely the result of the dearth of administrators who possess a first-hand experience of scientific technique; this, again, is partly due to a by no means negligible policy of deliberately excluding the scientific worker as such from important administrative positions.

It is difficult to assess the responsibility of the absence of scientific leadership for many of the grave problems confronting society. Under the conditions of modern civilisation, the community in general and not industry alone is dependent upon pure and applied science for its continued progress and prosperity. Under the influence of modern scientific discoveries and their applications in many directions other than industry, the whole basis of society is rapidly becoming scientific, and to an increasing extent the problems which confront the national administrator, whether judiciary or executive, involve factors which require scientific knowledge for their solution.

The Industrial Parliament visualised by Capt. Harold Macmillan, M.P., is an indication of the extent to which the changed conditions of the modern State are bringing us to consider the desirability of re-orientating representation on the basis of functional groups in order to link up knowledge and power more effectively in the service of the State and the general interest. Few aspects of civil life, for example, illustrate more aptly the hiatus between knowledge

and action than the field of transport. Whether we consider road transport, the railways, shipping, or aviation, the facilities which exist to-day are the outcome of scientific discoveries and their application, and the problems they present to society are in the main due to the absence of scientific organisation and control, and consequent development along haphazard lines ruinously expensive to the community as a whole.

In spite of the warning given by the recent Royal Commission on Transport about the absence of vision in such matters and its demonstration of the way in which ignorance and prejudice can bind burdens on the backs of posterity, as with railway development last century, neither in respect of the electrification of suburban services nor in the diversion of heavy goods traffic from the road to rail have any adequate steps been taken to give effect to the recommendations of the Commission, although both these recommendations should encourage employment and the recovery of the railways from their difficult position. In the absence of a more scientific policy, it is still common for a heavy goods lorry to do damage to a road in a few hours amounting to several times the combined value of the lorry and its load.

In other fields we have a number of problems created by industrial wastes. River pollution is becoming increasingly serious as fresh areas of the country are industrialised or the scale of industry increases. The beet sugar industry and the dairying industry provide two recent examples and also illustrate the assistance which scientific research can give in preventing or minimising the nuisance.

Again, the introduction of oil fuel for steamships immediately created a problem of waste-fuel disposal, and the layman could not have been expected to predict the serious consequences to marine and bird life and to many of our coastal resorts of a policy of dumping waste oil at sea. As in problems of atmospheric pollution, the solution lies almost entirely in the application of scientific methods of prevention and control, and in securing support for a scientific policy designed for the general advantage.

These and numerous similar problems have arisen through society using the results of scientific discoveries unguided by scientific and unprejudiced investigation of their reactions on the life of the community. Many such problems need not have become acute had an elementary amount of such foresight and scientific investigation been exercised in the early stages of the development of scientific discoveries, before the creation of vested interests or the growth of those local prejudices which generally hinder so strongly the development of a rational plan.

There are other wide fields in which the contribution of the scientific worker to the welfare of society is equally important and essential. Notably this is true in regard to food supply, where science is responsible not merely for protecting society against adulteration and for securing the purity of all kinds of foodstuffs, but also for the introduction of fertilisers giving higher yields per acre, for breeding new varieties which enable the zone of profitable cultivation to be extended, and for improved agricultural machinery and methods of cultivating and draining the soil. In addition, scientific research is urgently needed not only in the development and application of new insecticides and fungicides for the prevention or control of diseases or pests in the field, but also to an increasing extent to protect the harvested crops from damage by insect life, fungi, or moulds during storage. The colossal losses caused by insects and moulds to such products as cocoa, tobacco, dried fruit, grain, etc., in storage are as yet largely unappreciated by the public in Great Britain, in spite of the importance of storage space to a country which is so largely dependent upon imported foodstuffs.

In another but related direction, scientific workers are conducting investigations into the changes which occur in fresh fruit, meat, and fish in low-temperature storage and transport which have already assisted in improving the market condition of fruit, in minimising wastage during long voyages from overseas, and in improving the handling and transport of white fish so that a larger proportion of the catch can now be landed and marketed fresh than was formerly possible in half the time. The importance of such work in establishing on a firm basis the struggling fishing industry of Great Britain is obvious, apart from its national and social aspect.

Investigations of this type, closely related as they are to the welfare of society, are frequently long-range investigations requiring close co-operation between a number of classes of scientific workers. Only administration capable of taking a long-range and scientific point of view is competent to secure the necessary continuity or co-ordination, and in few fields is definite planning more important. Problems of food production and preservation should be taken out of the arena of political prejudices and debate into an atmosphere of impartial scientific examination.

Bacteriological Laboratories and Methods

Medical Research Council. A System of Bacteriology in relation to Medicine. Vol. 9. By J. A. Arkwright, S. L. Baker, M. M. Barratt, S. P. Bedson, J. C. Broom, H. C. Brown, H. H. Dale, P. Fildes, A. Fleming, A. D. Gardner, A. T. Glenny, J. Gordon, F. C. Happold, E. Hindle, B. C. J. G. Knight, J. C. G. Ledingham, R. J. Ludford, J. McIntosh, J. W. McLeod, P. G. Marshall, E. G. D. Murray, L. W. Proger, Wilson Smith, R. H. Stoughton, R. L. Vollum, L. E. H. Whitby, S. S. Zilva. Pp. 364. (London: H.M. Stationery Office, 1931.) 21*s*. net.

THE final volume of this work will be a boon to laboratory workers, and we welcome this plan of collecting in one volume the important laboratory methods, and congratulate both the writers and the editors on the very judicial selection they have made of the almost innumerable methods and variation of methods which are now employed in different laboratories.

Chap. i., dealing with design of bacteriological laboratories, is full of valuable suggestions, but, to the majority of bacteriologists, the plans are what we might dream of, only to waken and find they are not in the world of reality for us, and perhaps even be glad of that. We think it would have been better to have chosen something simpler, so as to give us an idea of what would be efficient and yet within the region of possibility from the not over-burdened exchequers of most universities and medical schools. The same may be said of the animal houses in Chap. xviii.

Chaps. ii. and iii. are excellent; but on page 40 the heading "Van Gieson's Stain" is surely wrong. Only the latter part is Van Gieson, and this is clear from number 5 under "Method" on the same page.

In Chap. iii., good though it is, there is the tendency to over-elaboration and the recommendation of methods which, under ordinary conditions, are impossible of attainment. Thus on page 63, to get blood serum, we have to go to the slaughter-house, reflect the skin from the neck of the animal, and so on. We may have been unfortunate, but we have never met the slaughterman who will allow us to spend the necessary time on such an operation, and we think such precautions are unnecessary. In this chapter it would have been valuable to have given some indication of simple methods of preparing culture media—methods which might be used by men who are working in the tropics and to whom a laboratory is not available. The elaboration in this chapter makes difficult what can be easily undertaken in any ordinary kitchen.

Chap. iv. deals very clearly with the determination of hydrogen ion concentration, and Chaps. v., vi., and vii. give valuable hints, and all that is necessary, on special cultivation methods and the isolation of single bacterial cells.

Many of the points discussed in Chaps. viii. and ix. are not found in ordinary textbooks of bacteriology, and should prove of great value, especially to the less experienced workers; but even the more senior ones will find valuable hints which may bring about improvements in their own methods. Chap. x., on viruses, collects the work which has appeared in various journals. Chaps. xii. and xiii. contain matters of great interest, and are well written. Their practical application is perhaps somewhat limited at present, but this, in our opinion, does not detract from their value.

Dr. Fildes's experience in serological investigations, and that of Dr. Glenny on toxins and antitoxins, would lead one to expect chapters of very practical value, and this expectation will be realised by those who read their two valuable communications in Chaps. xiv. and xv. The same can be said of Chap. xvi., the joint work of McIntosh and Dale.

Chap. xvii. will be welcomed by all heads of laboratories. It contains an immense amount of information of practical value, and gives details about which we venture to say most of our workers are profoundly ignorant, and which should be known to all. The methods may be too elaborate to be carried out in a laboratory the staff of which is very limited, and the apparatus too expensive; but from the mass of information given it will be possible to obtain a great deal which will be applicable and which must prove very helpful.

In Chap. xviii., Dr. Arkwright has summed up very well the methods by which variants are produced, and this should clear up a good deal of confused work on this subject.

Vitamin deficiency, electric charges, and the effects of ultra-violet rays, are briefly dealt with in Chaps. xix., xx., and xxi.

In Chap. xxii. we have a description of the Rideal-Walker test and the Chick-Martin tests for estimating the power of disinfectants. The authors state that there are so many factors concerned in this testing that the value of the disinfectant can only be judged from experiments in which the precise conditions under which it is to be employed are closely followed. It seems to us rather a serious omission that no reference is made to the fact that an established coefficient for

B. typhosus may be entirely different from the coefficient for another organism, for example, the streptococcus; or that one disinfectant useful for the destruction of certain bacteria is practically useless in the same dilution for others.

This volume contains the general index for the whole work. We welcome this index very much.

J. M. BEATTIE.

Theory of Algebraic Numbers

Foundations of the Theory of Algebraic Numbers. By Prof. Harris Hancock. Vol. 1: *Introduction to the General Theory.* (Published with the aid of the Charles Phelps Taft Memorial Fund, University of Cincinnati.) Pp. xxvii + 602. (New York: The Macmillan Co., 1931.) 8 dollars.

THIS is the first volume of Prof. Hancock's work and is intended as an introduction to the second volume. Its size shows that he is engaged in no light task. His object is to help in making the theory of algebraic numbers more accessible, more attractive, and less difficult. He obviously has in mind the English-speaking student, or at any rate those for whom German is a source of difficulty. For these, he has undoubtedly made more accessible and more easily readable the difficult theories of Dedekind and Kronecker, as well as the more elementary topics such as algebraic integers, quadratic and cubic fields, an introductory account of ideals, Hilbert's norm residue symbol, the law of quadratic reciprocity, and applications to Fermat's last theorem. The beginner will find much to interest him, as many of the chapters are self-contained and will be useful in supplementing a course of lectures.

The author also states that the theory of algebraic numbers is presented here from a heuristic point of view with the hope that through this method of treatment the innate relation of the general number theory to the function theory, algebra, algebraic (Abelian) integrals, and other branches of mathematics will be further developed, and eventually generalised into a united arithmetised entity, one contributing to the advancement of the other. But I think the author's hope will not be fulfilled, and that, in fact, he has missed an obvious opportunity of increasing considerably the value and usefulness of the present volume. The most important developments in the arithmetical theory of algebraic numbers during the present century have arisen from its association with the theory of groups and the application of this theory to the enunciation and proof of arithmetical theorems. Perhaps Hilbert was the first to emphasise the great arithmetical importance of expressing the properties of an algebraic field by means of its Galois group. It is only about five years ago that Artin showed that the general law of reciprocity (quadratic, cubic, etc.) in any field was most simply and beautifully stated as an isomorphism between the group of the class of ideals in the given field and the Galois group of an appropriate Abelian field.

The ambitious student who means to go deeply into the subject of algebraic numbers—and naturally it is an ambitious student who will contemplate mastering two large volumes—finds no reference whatever to groups. In fact, it seems as if the author made every endeavour to avoid using the language or methods of group theory. Thus in his chapter on algebraic fields of rationality containing some of the Galois theory, where nowadays one would have considered the notion of a group almost indispensable, he speaks of normal realms (that is, fields) and their divisors, but never mentions groups (except with its non-technical meaning) or subgroups or indices. Again, in dealing with classes of ideals, there is no mention that the classes form a group (an Abelian group, of course), a fact of vital importance in advanced work, which would enable him to simplify some proofs. Undoubtedly an introductory chapter on Abelian groups, and its application whenever possible, would have been very desirable and added considerably to the value of this volume.

L. J. MORDELL.

Towards Unity

The New World-Order. Essays arranged and edited by F. S. Marvin. (The Unity Series, 9.) Pp. vi + 188. (London: Oxford University Press, 1932.) 8*s*. 6*d*. net.

EVENTS of the post-War period are forcibly and unmistakably driving home the lesson that the future welfare of the human race is vitally dependent upon world co-operation. The days of self-sufficient nationalism, of splendid isolation, of Monroe doctrines, are clearly numbered, and it is widely felt that the more quickly such venerable creeds are abandoned the brighter will become the prospect for civilisation at large. How soon events will force the political unity that, in some form or other, appears inevitable, it would be rash to prophesy; but if the process of unification is to succeed, it can only be upon a previous basis of intellectual sympathy and understanding. It is in the intense realisation of this cardinal fact that Prof. Marvin and his fellow-thinkers are striving

to establish a wider outlook among the educated classes; and the signs indicate that they are meeting with an encouraging response—even in the most conservative quarters. Personal contact between scholars of different countries is so sure a method of breaking down the barriers of ignorance and prejudice that the present difficulties of foreign travel are to be deplored; but such books as this and the previous volumes of the "Unity Series" show what might be done by the printed word if sufficient enthusiasm—and funds—were available.

The present book is based upon lectures delivered at the two Unity History schools held at Danzig (1929) and Stockholm (1931) respectively, the special emphasis at both meetings being laid upon the growth of international co-operation. As Prof. Marvin justly observes, the fundamental law of human unity is best expressed in science, "because it has sprung from experiences common to all men and been elaborated as an articulate and marvellous system to which all civilisations have contributed"; and since momentous events have happened in science in the last few years, two scientific essays by Prof. Dingle hold pride of place in this collection. They are entitled "The Atom" and "The Universe", and are written with Prof. Dingle's accustomed skill and lucidity; their infusion with the author's philosophical views is just sufficient to add zest to the themes without deflecting attention from the facts. The balance of the book is preserved by essays upon English literature, Swedish architecture, international law and finance, economic success and failure, contemporary education, race problems in industry and culture, and the present position in biology. All are provocative of thought, and if the reviewer found Prof. Marvin's essay on contemporary education the most stimulating and attractive, the general level is so uniformly high that, among a dozen readers, there would doubtless be a dozen different orders of preference. We may perhaps mention that anyone who wishes to have details concerning the Unity movement may obtain them from Mrs. Innes, 29 High Oaks Road, Welwyn Garden City, Hertfordshire.

E. J. H.

Physics in Physiology

Groundwork of Biophysics. By Dr. G. M. Wishart. Pp. vii + 344. (London: G. Bell and Sons, Ltd., 1931.) 12*s.* 6*d.* net.

EVERYONE who teaches physiology will sympathise with Dr. Wishart in the experience which he has evidently had to induce him to write this book. The great majority of those who come to be taught physiology have had instruction in physics, but having also passed an examination in the subject have laid aside the burden of all that that examination imposed on them. If only this were not so and their training in physics had formed in them the habit of thinking about the world around them as such training should, they would find their study of physiology easier and more fruitful.

This work is written to supply what such students have failed to retain or omitted to acquire. But it is clearly not intended to be an introduction to the study of physiology. The reader is supposed to know what is meant by such things as reflex action and the respiratory quotient, that the excitation wave of the heart begins at the sino-auricular node, that the cells of the pancreas at rest are packed with granules, and that its secretion is inhibited by atropine. He is supposed, in fact, to have been introduced to physiology and to have discovered that he has to go back to what he thought his examination had entitled him to discard. Accordingly he is taken again over the gas laws, the structure of the atom, the law of mass action and the physical principles underlying the methods employed in the investigation of selected problems in physiology.

The question may arise, whether this plan of work is the ideal one, but if it is found in experience to give good results, if students are induced by these means to study physiology as, for example, Bayliss gave them the opportunity of doing in his "Principles", no one need quarrel over this. There may be those who still regret what they regarded as the dismemberment of physiology, when biochemistry began to be treated as a separate subject. Some of them may be dismayed at the prospect of further dissection leading to the severance of biophysics also as a distinct study. But that is not imminent. There is much in this book that the biochemists are concerned with, and there are, on the other hand, certain things that require physical treatment, the hydrodynamics of the circulation for example, which are left for the teacher of physiology to deal with. It is clearly meant to strengthen his hands, not to restrict his province.

There are chapters in the book in which the students to whom it is presumably addressed, those who failed to apprehend the principles which their instructors in physics and chemistry expounded to them, might be grateful to Dr. Wishart if he had departed, as in other places he has, from

the letter of traditional methods of exposition, methods which must from his premises be sometimes at least unsuccessful. But that the book can and should be helpful there is no doubt; it would be still more helpful if all parts equally were treated with the same freshness and originality of sympathetic exposition.

Short Reviews

Cambridge Excavations in Minorca. Trapucó. Part I. By Dr. Margaret A. Murray. With Chapters by Dr. Edith M. Guest, Dr. C. Ainsworth Mitchell and T. J. Ward. Pp. 50 + 52 plates. (London: Bernard Quaritch, Ltd., 1932.) 12*s*. 6*d*. net.

IN recent years a good deal of attention has been paid by prehistorians to the Balearic Islands, mainly in the hope of finding evidence of maritime trade between Spain, Sicily, and the south of France and the spread of culture between these centres during the copper age, but partly because these islands contain in considerable numbers certain monuments of large unworked stones, which, though unique, bear some resemblance to the megalithic monuments found elsewhere near the coasts of western and northern Europe. The most striking of these monuments are *talyots* and *taulas*, but whereas the former, circular buildings of rough masonry, are found both in Majorca and Minorca, the *taulas* occur only in the latter island.

It was to examine these monuments, and, if possible, to ascertain their age and purpose, that an expedition was sent out to Minorca by the Cambridge Museum of Ethnology. This expedition, which was under the command of Dr. Margaret Murray, carried out most careful excavations, found an abundance of pottery and other objects, which are attributed to the bronze and early iron ages, and took careful measurements of the *taulas* and their surroundings. While the expedition scarcely succeeded in discovering the purpose for which these great T-shaped monuments were erected, though they are concluded to have been objects of worship, it has finally disposed of the theory tentatively advanced by Cartailhac, that they were the central pillars of domestic structures.

The book is well got up, with numerous plates, giving views of the monuments and drawings of the pot-forms, so that, if the expedition has not wholly succeeded in solving all the problems involved, it has provided for archæologists a series of pottery extending over more than a millennium.

H. J. E. P.

Growing Up in New Guinea: a Comparative Study of Primitive Education. By Margaret Mead. Pp. xi + 285 + 16 plates. (London: George Routledge and Sons, Ltd., 1931.) 12*s*. 6*d*. net.

THIS is the second of a series of studies dealing with childhood and adolescence among relatively primitive peoples, undertaken by Dr. Margaret Mead for the purpose of investigating the original nature of the child in the light of the effect of varying types of environment and education. She has already published a volume on the adolescent of Samoa. Here she is concerned with the childhood and youth of the Manus, a sea-dwelling people of the Admiralty Islands. Each of a total of eighty-seven children was studied in detail, inheritance, family background, physical and mental character, and so forth being noted. The method of study also entailed an investigation of the social structure of the village, the system of marriage and relationship, and the economic conditions. The results of these latter investigations are reported in the body of the book only in so far as they bear on the main problem; but further information is given in appendices.

Dr. Mead's record is of the greatest interest, especially as the life of the adult, which is lived in conditions almost puritanical in their harsh rigidity, is in striking contrast to the licence of childhood and among the boys in adolescence. Children are instructed early in respect for property; but beyond that they enjoy absolute freedom, and exhibit a lack of subordination to their parents, especially the indulgent father, which appears to admit of no preparation for the complete subjection to their elders to which they must submit when the girl attains adolescence and the boy marries. It is evident, however, that the early period of apparent licence has in reality been a term of rigorous, if imperceptible, instruction by the force of society. Both sexes have already absorbed innumerable taboos which are obeyed as a second nature. Both in respect of the main problem, and incidentally as a record of a somewhat unusual type of social and economic organisation, Dr. Mead's book is highly instructive.

Tabulæ Biologicæ Periodicæ. Herausgegeben von C. Oppenheimer und L. Pincussen. Band 1 (= *Tabulæ Biologicæ*, Band 7.) Nr. 1. Pp. iii + 144. Nr. 2. Pp. 145-240. (Berlin: W. Junk, 1931.) Band 7 (4 Hefte), 55*s*.

THE first six volumes of "Tabulæ Biologicæ" have already been noticed in our columns. The seventh, of which the first three parts have been received, gives vol. 1 of "Tabulæ Biologicæ Periodicæ". The objects of this journal are to continue the collation of biological data recently published and to substitute corrected figures, based on more accurate estimations, for those already given in previous volumes. The principal data in the new numbers are as follow: series of figures concerning different aspects of photochemical reactions, chemical, physical, and spectrographic data of hæmoglobin and chlorophyll and their derivatives, a very useful table of the vitamin content of foodstuffs, a lengthy list of plant chromosome numbers (occupying more than a hundred pages), tables of the iodine content of vegetable and animal foods, as well as data referring to phonetics, and a number of other miscellaneous constants of biological interest, such as the physico-chemical constants of blood and tissue fluids. The collection of these data is of great value to all biologists. The usefulness of the parts, however, would be greatly enhanced if it were

possible to publish a detailed cumulative index with each. The volume may be recommended to all biochemists, physiologists, and biologists as a useful work of reference.

A Book of General Science. By M. J. Hilton. (Macmillan's Canadian School Series.) Pp. xiv + 399. (Toronto: The Macmillan Co. of Canada, Ltd.; London: Macmillan and Co., Ltd., 1931.) 7*s.* 6*d.* net.

IN this book the subject of general science is dealt with in an interesting way, and is well illustrated. Commencing with a chapter on systems and standards of measurement, the book deals in turn with air, water, life, energy, the earth's crust, and the solar system. Each chapter contains descriptions of experiments; and the necessary apparatus required for the experiments is described, with the method of procedure, what to observe, and an explanation of what has taken place. The atmosphere and the methods employed to measure its pressure lead to the subject of elementary meteorology. A chapter is devoted to the uses to which man puts the properties of air. More space might have been given with advantage to the sections dealing with biology and energy. The book is, however, well worth the attention of teachers and students of general science.

An Introduction to Egyptian Religion: an Account of Religion in Egypt during the Eighteenth Dynasty. By A. W. Shorter. Pp. xv + 139 + 8 plates. (London: Kegan Paul and Co., Ltd., 1931.) 8*s.* 6*d.* net.

THIS brief account of the religion of ancient Egypt in the eighteenth and early nineteenth dynasties is intended both for the general reader and for those who are entering on the study of Egyptology. During the last twenty years, our knowledge of Egyptian religion has been much amplified by the labours of the archæologist, and a textbook such as this, which incorporates the new material, was greatly needed. Mr. Shorter has based the whole of his descriptive matter on the monuments, so that the reader unversed in the technique of Egyptian studies may learn how our knowledge is acquired. Akhenaton and Aton worship are not unduly emphasised, as so often happens in the discussion of eighteenth dynasty religious beliefs, though their significance is appreciated to the full. The account of Queen Hatshepsut is, in its way, the best thing in the book.

Colloid Aspects of Food Chemistry and Technology. By Dr. William Clayton. Pp. viii + 571 + 6 plates. (London: J. and A. Churchill, 1932.) 36*s.*

WE start life as a quivering lump of jelly, and most of our foodstuffs are colloids. Food chemistry and food technology have passed beyond the stage of mere analysis into a field of science which engages all the important physico-chemical problems of colloids. Hence the need for a textbook which summarises the voluminous and scattered literature. Such problems as the staling of bread, the foaming of milk, the homogenisation of cheese, the sandiness in ice-cream, the froth on beer, the fining of wine, the clarification of water, to name but a few, all involve colloidal chemistry. Such a work will soon be found invaluable in the food laboratory, and the author's reputation ensures its thoroughness.

In addition to copious references in the text, a classified biography of nearly a hundred pages, containing more than two thousand references, is included, and a valuable feature is a glossary of the new terms which have crept into the subject.

Vorlesungen über vergleichende Anatomie. Von Prof. Otto Bütschli. Lieferung 5: *Leibeshöhle.* Überarbeitet und herausgegeben von C. Hamburger. Pp. iv + 381-490. (Berlin: Julius Springer, 1931.) 16·80 gold marks.

THIS section of Bütschli's textbook of comparative anatomy, commenced by Blochmann and completed by Hamburger of Heidelberg, deals with the body cavities. One half of the text is devoted to the invertebrates and one half to the chordates. The development of the cœlom, mesenteries, pericardio-peritoneal septum, and diaphragm is traced with the aid of simple diagrams. The abdominal pore is traced through cyclostomes, fishes, and birds. The facts of embryology are incorporated in the text with clarity. The absence of theorising and the excellence of the diagrams are to be commended.

Mechanics for Beginners. By F. Barraclough and Dr. E. J. Holmyard. (Dent's Modern Science Series.) Pp. viii + 214 + 8 plates. (London and Toronto: J. M. Dent and Sons, Ltd., 1931.) 2*s.* 6*d.*

THE particularly difficult problem of making the principles of mechanics interesting to the beginner, without at the same time sacrificing scientific accuracy, is very successfully accomplished in the well-known style of which Dr. Holmyard may be said to be the pioneer. The result, with its special emphasis on the historical development of the science, is as much a fascinating reader as a textbook. N. M. B.

Cicatrisation et régénération. Par Prof. Jacques Millot. (Collection Armand Colin: Section de biologie, No. 141.) Pp. 204. (Paris: Armand Colin, 1931.) 10·50 francs.

A BRIEF account of the present views of wound-healing and regeneration of parts in the animal kingdom, with special regard to the more recent experimental methods in the lower animal forms. The physiological factors involved are analysed, and there is an interesting account of the corresponding compensatory mechanism in plants.

Hunting Insects in the South Seas. By Evelyn Cheesman. Pp. xi + 243 + 8 plates. (London: Philip Allan and Co., Ltd., 1932.) 10*s.* 6*d.* net.

MISS CHEESMAN has travelled widely among the Pacific islands and is a keen observer of insect life. In this, her latest book, she gives a very readable and interesting popular account of insect hunting and other experiences in Tahiti, the Marquesas Islands, and the New Hebrides.

The Enclosure of the Zuider Zee

By Dr. Brysson Cunningham

May 28 last will always be a notable date in the annals of the Netherlands. On that day, in the presence of distinguished government officials, the crucial deposit of clay was made which finally and entirely cut off the waters of the Zuider Zee from any intermingling with the outer sea. The means of severance, it is true, is but a narrow earthen embankment, stretching like a taut cord or strip of ribbon, for a length of 18½ miles, from the eastern extremity of the former island of Wieringen to the Friesian coast, but it suffices to create an impassable barrier, intersected only by three locks for purposes of navigation and by two groups of sluices for surplus water discharge, and it marks the commencement of a distinctly new regimen for the impounded area.

Hitherto, this vast expanse of nearly a million acres of water has been an arm of the sea; at present, it is an inland lake, the greater part of which is destined to be pumped dry and converted into agricultural holdings, while the residue will constitute a reservoir for fresh water, instead of salt water, to be utilised, apart from navigation, as a source of supply for irrigation and farming. In the ultimate result, the transformation will mean an increase of seven per cent in the area of the whole country and of ten per cent in the area of arable land. Relatively, it is as if Holland were enlarged by the addition of a province roughly equivalent in size to Kent or Essex or Sussex.

In Nature of Sept. 21, 1929, following a visit to the site of the works, I gave an outline of the scope and probable effects of this tremendous project, which has, for several centuries past, occupied the minds of the Dutch people and exercised the ingenuity of their engineers. Living, as they do, within a territory of restricted extent, much of it lying below sea-level and subject to tidal inundation, they have been compelled, at much trouble and expense, to win from the sea such tracts as were possible in order to find scope for the natural expansion of the population and their industrial activities. According to statistics published in 1924, there had then been an increment of about 250,000 acres, gained since the year 1846. Including the exploitation of land previously considered as waste, the total increase in arable land during the last century has been rather more than a million acres, equivalent to a rate of 10,000 acres a year, but against this must be set off the loss due to building and engineering operations, latterly at the rate of about 6000 acres a year. This leaves a

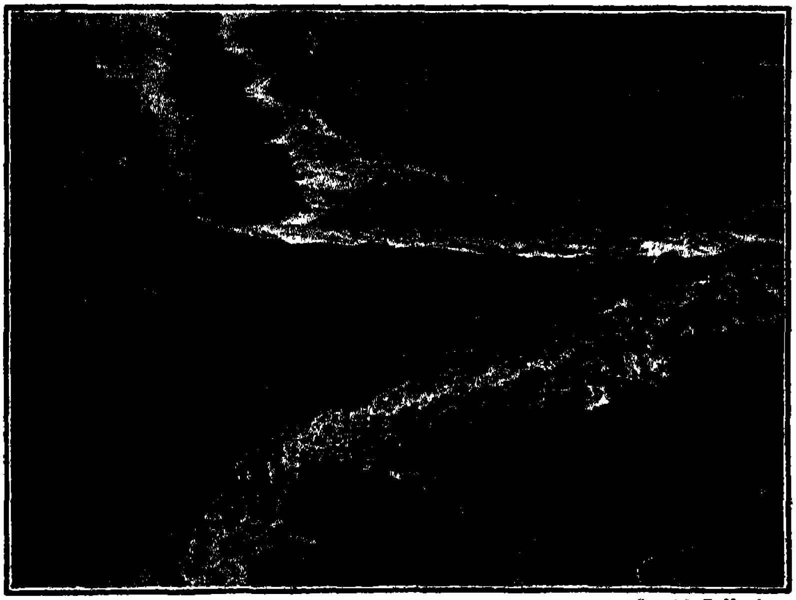
Fig. 1.—The concluding stage in the enclosure of the Zuider Zee, showing plant in operation.

net annual gain of 4000 acres per annum; but the population is growing fast, and there is at the present time a distinct shortage of arable land.

The acquisition of so large an area as that covered by the Zuider Zee naturally involved a multitude of complex problems, so that it was only after protracted consideration and many financial and legislative delays, inseparable from an undertaking of such magnitude, that the work was actually commenced in 1920. It has therefore been in progress over a period of twelve years. In accordance with the plan prepared by the late Dr. C. Lely, it involved the construction of a main dyke, or embankment, which, starting from the little village of Van Ewijcksluis on the eastern coast of the province of North Holland, extends across a deep strait of 1½ miles to the western side of the island of Wieringen, to be resumed at Den Oever at the eastern extremity of the same island, and thence, apart from a slight curvature at the eastern end, to stretch in a straight line eastwards as far as the village of Zurig on the coast of the province of Friesland. South of the main dyke, or enclosing dam, a series of four separate areas or 'polders' with an aggregate content of about 550,000 acres, is to be reclaimed by pumping out the water into a central lake of about 270,000 acres, provisionally designated the Yssel Lake and designed to receive the discharge of the rivers Yssel, Zwartewater, and Vecht from the mainland. The first of these polders has, in fact, already been reclaimed and the progress made thereon will be referred to later. For the moment, attention is directed to the concluding stages of the work in connexion with the main dyke, which, with the four polders, is shown in the map accompanying my article in NATURE for Sept. 21, 1929.

At the time of writing the above article, the island of Wieringen had already been joined up to the mainland and a substantial roadway formed across the Amstel Diep. The work was proceeding in the main dyke from both extremities, namely, eastwards from Den Oever and westwards from the Friesian coast across the shallows of Makkummerwaard to the site of the navigation locks at Kornwerderzand, a distance of 2½ miles. Approximately half-way between the Kornwerderzand and Den Oever, lies another shoal area, called the Breezand. Advantage was taken of its existence to commence, in 1929, a detached mid-sea section, which has been extended eastwards and westwards to link up with the coastal sections. The intervening spaces were crossed by two deep 'guts' or channels, the Vlieter on the west and the Middelgronden on the east, in which the depth of water increased to as much as 10 metres. These channels were first treated with shallow deposits of material to form 'sill dams', reducing the depth of water over them to more convenient limits. The material consisted of a layer of boulder clay protected by a covering of 'mattresses' of brushwood, weighted down in position by means of heavy stone fragments and secured by stakes driven into the ground. The mattresses were arranged to extend appreciably beyond the limits of the main dyke, in order to ensure protection from scour. These sills were completed in 1930.

When, a year later, preparations were made to proceed with the formation of the dam itself on these sills, it was found that the brushwood, while maintaining its position, had suffered a good deal



Copyright K. Maasland.

FIG. 2.—The last gap in the Vlieter channel.

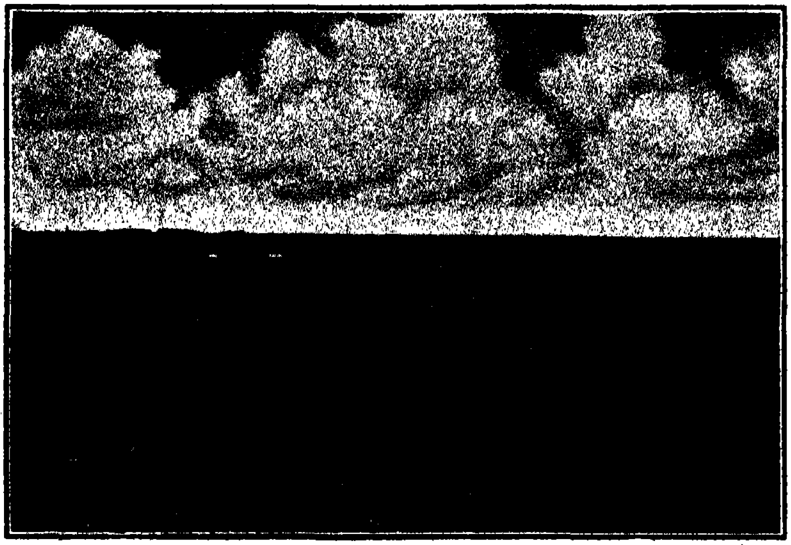
from the attacks of marine borers, and that considerable corrosion of the galvanised binding wire had taken place. The sill on the Middelgronden had deteriorated to a greater extent than that on the Vlieter, and, accordingly, first attention was given to the execution of the main structure across the former. It was completed in November 1931. The work carried out during the first half of the current year has been the final closing length across the Vlieter.

The method of forming the main dyke consisted in first depositing a substantial body of boulder clay to form a nucleus and a frontal barrier. Behind this was discharged a mass of sand (dredged within the limits of the Zuider Zee and transported to the site), which was covered in turn by a layer of clay, or boulder clay, the latter being a specially tough variety of glacial origin, containing boulders, found in the floor of the Zuider Zee in various places, as well as on the island of Wieringen and on the south coast of the province of Friesland. It has proved eminently suitable for resisting the scouring action of currents, and its qualities in this respect were

fully tested during the period of concentrated flow while the tidal water was passing in and out of the gradually contracting gap, as can be well seen from the photographs in Figs. 1 and 2 taken the day before the final closure was made. I had an opportunity myself of witnessing the concluding stage of the construction of the dam flanking the new north-west polder, and was much impressed by the resistive capacity of the material. As a final covering, the exposed surface of the embankment is protected below the water-line by mattresses of brushwood, weighted with rip-rap, and above the water-line by a stone facing of basalt or limestone, brought from Germany.

A point of interest that requires mention is the effect of the constructional operations on the tidal conditions. It is stated that up to the end of 1929 (with the exception of a period in 1924 due to the closing of the Amstel Diep between the island of Wieringen and the mainland), there had been scarcely any changes in the tidal movement. Afterwards, as a result of the formation of the sills in the channels of Middelgronden and Vlieter, the velocity of flow across the line of the dam increased to a marked degree, reaching 3-3¼ ft. per second, while, at the same time, certain changes were manifesting themselves in the rise of the tide in the outer area, very perceptibly in the Texel Strait and less noticeably in the Vlie Strait. These changes will require further observation before they can be definitely evaluated, but they appear to be of the order of 6-12 inches, generally, in the Wadden Zee.

Concurrently with the construction of the main dyke, operations have been in hand for developing the new north-west polder (Wieringermeer) of 50,000 acres, which was reclaimed by the formation of an auxiliary dyke in advance of the main project. It was pumped out in 1930, the quantity of water discharged within a period of six months being more than 132,000 million gallons. The land, of course, had been covered with sea water for centuries and the soil was heavily charged with salt. The mean salinity ranged from ½ to 2 per cent, the variation being due to the proximity, in certain parts, of fresh-water outlets from land drainage systems. A surface soil chart is in course of preparation, for which purpose borings are being taken on every plot of 5 hectares to a depth of 1½ metres. The result of the investigation in regard to the first polder-section shows that the surface layer is of unequal thickness and consists mainly of sand, under which clay is often found, and, further, of a small percentage of clay and sandy clay with a small amount of peat. There appears, however, to be considerable dissimilarity of structure in different areas.



Copyright K. Maaskant.

FIG. 3.—Harvesting the first crop of rye on the Wieringermeer.

One of the earliest and most important problems to be solved before cultivation could be attempted was that of internal drainage. The first intention of providing a network of shallow trenches was abandoned, as it failed to drain the sub-soil sufficiently, or to remove the salt. Covered-in drains would have been preferred, but the cost was high, and, finally, recourse was had to a system of open trenches on a large scale. They have a depth of 60 cm. and are arranged at distances apart of 11 metres in clay areas and of 15 metres in sandy areas. In the spring of 1931, the sampling of soil showed that about 400 hectares of sandy ground in polder-section No. 1 was suitable for cultivation (Fig. 3), while the ground with a higher clay composition still retained an excess of salt. In the autumn, further tests were made, as a result of which, 1050 hectares were declared suitable for planting with cabbage, or sowing with winter barley and wheat, while 900 hectares were treated with a mixture of grass and clover seed to develop permanent pasturage.

The remarkable experiment of bringing the Zuider Zee into a state of agricultural productivity will be watched with the greatest interest, as its economic value to the inhabitants of the Netherlands is a matter of no little importance. In 1924, the outlay on the main dyke and the reclamation of the polders until the latter attain their full cultivable state was estimated at about thirty million pounds, to which interest over the unproductive period would add some fifteen millions, making a total of forty-five millions. The profits to be derived had, of course, to be evaluated on a more or less speculative basis, but they were put at a figure of fifty-two millions. In 1928, it was reported that actual costs to date had exceeded the estimates by some five millions, due to the rise in prices of public works, particularly dredging, and certain constructional difficulties, which could not have been foreseen. Since then, there have been

some reduction in prices, and if the favourable conditions continue, it is hoped to complete the undertaking without further excess and even with some reduction of the debit.

Everyone will hope that this enterprise of high courage and endeavour will be crowned with the success it deserves. Very great credit is due to its promoters and to the engineering staffs who have faced and overcome all the difficulties which have arisen from time to time. I am indebted to Dr. Ir. J. A. Ringers, director-general of the Rijkswaterstaat, for the photographs reproduced and the greater part of the information on which this article is based. For several years he was in charge of the operations, as director of the association of contracting companies expressly formed for the execution of the project, known as the Maatschappij tot Uitvoering van Zuiderzee-werken. On the Government side, mention should be made of the Zuiderzee Board, with Dr. H. Colijn at its head, and the office of the Zuiderzee works, to which Mr. V. J. P. de Blocq van Kuffeler is director-general.

Basic English *

ABOUT three centuries have now elapsed since three master minds—Descartes, Pascal, and Leibniz—espoused the cause of a *lingua franca*, and ingenious attempts are still being made to devise or construct a synthetic language for international use. The case for the adoption of an international *auxiliary* language (I.A.L.) is stronger now than it has ever been, but results have so far been disappointing. Though several of the projects that have been put forward might, with more or less modification, have proved satisfactory, practically none, with the exceptions of Volapük and Esperanto, has gone far beyond the threshold of the academy or the study. As Prof. Donnan has said, so far as numbers are concerned, Esperanto is the greatest and most successful linguistic experiment that the world has seen. The causes of failure are mainly psychological. Mankind is not ruled by reason, and the idea or ideal of an I.A.L. does not appeal to man's pleasurable emotions or to his primary instincts, except probably to that of pugnacity, for enthusiasts in this field have shown almost as little brotherly love to competitors as did rival religionists in days now happily past. Another obstacle has been the widespread fallacy that anything artificial is *ipso facto* inferior to its natural counterpart. However, the cause endures, and the latest apostle, Mr. C. K. Ogden, comes forward with a simplified form of English, called Basic, to compete, and peradventure to conquer, in the field of international linguistics.

The main features of Basic, which derives its name from the initial letters of the words, British, American, Scientific, International, Commercial, are : a very restricted vocabulary of nouns (600) ; the use of only sixteen or seventeen verbs, including come, get, give, go, keep, let, make, put, seem, and a few others ; the use of 150 adjectives and a number of prepositions, adverbs, pronouns, and conjunctions, but apparently no interjections. The grand total is 850 words, but further nouns can be created by adding the suffixes -er, -ed, and -ing to 300 of the primary nouns. Word-order is essentially the same as in good English, although the adverb is banished to the end of the sentence. Pronunciation is to be standardised by means of gramophone records, but spelling is not to be simplified or made phonetic.

Perusal of the Basic textbooks leads to the conclusion that simple conversations could be carried on with the above 850 words and simple derivatives, although in places the phraseology would appear strange, ambiguous, or prolix. Thus, a witch is " a woman with strange powers " ; a widow is " a woman not married again " (every *divorcée* who does not re-marry is thus conveniently made a widow !) ; and a baby is " a diminutive object ". We must not study or use Basic, but " go into " it and " make use of " it. If we are in difficulty, we must not ask but " make a request " for explanation ; we must " make dry " our eyes if we cry ; and " get off the ship " when we come to land. " Friday ", we are told, " is the day all the week's payments are made " ; and for dinner we are asked, " What sort of beef will you have, cooked in the oven or over the fire ? " (roast, or boiled, fried, or stewed !). Mercifully, we never " die ", we merely " take our last breath " or " go to our end ".

This simple but circuitous language would be useful to a foreigner wishing to learn something better than ' pidgin ' English ; it is easy to acquire and to use, and it would serve him as a good introduction to English proper ; but it seems certain that the 850 words, *plus* the simple derivatives of the primary nouns, would not suffice for any except very elementary purposes. It is true that provision is made for expanding the primary vocabulary to 1000 words by including in it 150 names of general utility, and further additions, for example, 12 international names, 12 (only) names of sciences, and other proper names are also permitted ; but would the foreigner remain content with these ? Would he not ask for more, in order to read English newspapers and literature, as well as to converse and correspond with educated Englishmen ? English-speaking peoples themselves would not find it easy to talk ' pure ' Basic ; they would be hard put to it to remember which nouns were in the vocabulary and which were not. For international use, it would be difficult to standardise this language, and the fact that it has a national basis would undoubtedly impede its adoption.

* " Basic English Applied (Science)." By C. K. Ogden. With specimen Translations in Chemistry, Physics, and Biology, by R. Michaelis. Pp. 88. " The Basic Traveller : and other Examples of Basic English." By L. W. Lockhart. Pp. 119. " The Basic Vocabulary : a Statistical Analysis with special reference to Substitution and Translation." By C. K. Ogden. Pp. 96. " The Basic Dictionary : being the 7500 most Useful Words with their Equivalents in Basic English ; for the Use of Translators, Teachers, and Students." By C. K. Ogden. Pp. xx + 106. " Debabelisation : with a Survey of Contemporary Opinion on the Problem of a Universal Language." By C. K. Ogden. Pp. 171. " Basic English : a General Introduction with Rules and Grammar." By C. K. Ogden. Pp. 95. (London : Kegan Paul and Co., Ltd., 1930–1932.) Each vol. 2*s*. 6*d*. net.

From the literary point of view, it is a relief to read that "although Basic is clear and precise at the level for which it is intended", it has no literary claims. It seems to discard most of the canons of good style, for example, to prefer the concrete to the abstract, and to use the single word in preference to the circumlocution. The author has little use for "the antic haverings of a pedantic pedestrianism in quest of Pure English"; so he allows us cheerfully to mix up 'shall' and 'will', to use noun-adjectives *ad lib.*, and to end a sentence with a preposition.

The fact that Basic has no literary pretensions and is yet recommended as the I.A.L. for science, suggests that its author has a poor opinion of the literary value of scientific writing. If so, he is not alone; but if present-day style in scientific writing is generally poor, it is at least preferable to that of Basic. A style that is both concise and precise is indispensable to good scientific writing, and the scientific author who uses two words where one would suffice, is as much a malefactor as the man who makes two blades grow where one grew before is a benefactor to his kind. Although Mr. Ogden realises that a much larger vocabulary is needed for science than for more mundane purposes, it seems certain that many more nouns would be required than he contemplates. As in other national languages, the resources of English are proving more and more inadequate to keep pace with the multiplication of new concepts, so that science would appear to need an I.A.L. possessing a vocabulary of constructed words that would allow of constant and regular expansion, rather than a language like Basic the chief aim of which is to restrict the vocabulary to the smallest possible number of words. What is sauce to the Kafir is not necessarily sauce to the chemist.

In "Basic English Applied (Science)", Basic versions are given of three scientific communications: a paper from the *Journal of the Chemical Society* on the analysis of light oils and motor spirits; a lecture on the mathematical problem of aerodynamics; a letter to NATURE (**123**, 601; 1929) on spectrographic analysis of animal tissues; and a few abstracts of patents taken from the *Nickel Bulletin*. Lack of space precludes a detailed appreciation of these efforts, and it must suffice to say that in the writer's opinion the translator has succeeded in making his translations generally intelligible, but that the 'wordiness', the frequent lack of precision, and the frequently curious phraseology all combine to make one hope that scientific English will never descend "to the level for which Basic is designed". The following are some examples in which Basic wording (given in italics) is held to be deficient: Desiccator—*drying vessel*; retort—*heating apparatus*; alloy—*mixed metal*; boiling—*at vapour temperature*; evolution —*development*; describe—*give details of*; distil—*give a distillation*; viscous-fluid flow—*motion in liquid or gaseous mediums*. The method has been developed quantitatively—*By an expansion of the method it is possible to get the amount of the elements present*. A detailed account of the work will be published shortly—*A detailed account of the work will be printed shortly*.

The somewhat unconventional ending to one paper, "*It was very kind of the Director of Fuel Research to let the writer put this paper into print*", prompts the present writer to sum up his conclusions as follows: *It was very kind of the Editor of* NATURE *to let the writer have these books and give his opinions of them; they are bright* (clever) *and interesting and in places they give amusement; but they do not give him strong belief* (convince him). *Though he is of the opinion that the new language* (old wine in a new vessel) *will be of use to men of other countries when they make a start to learn our language, he has the hope and makes the request to a Higher Being* (prays) *that it may at no time come into use for Letters or for Science. It might make better the language of trade; it is almost not possible to make it worse.*

In making this attempt at 'an attempt', the reviewer was surprised and perplexed not to find the word "Basic" in the 850-word vocabulary, either among the 400 "necessary names" or the 200 "common things". Is this an omen?

Obituary

PROF. ROLAND THAXTER

PROF. ROLAND THAXTER, of Harvard, died on April 22, at the age of seventy-three years. He was born at Newton, Mass., on Aug. 28, 1858, and graduated at Harvard University in 1882, proceeding to post-graduate work there until he was appointed mycologist at the Connecticut Experimental Station in 1888. Three years later he returned to Harvard as assistant professor of cryptogamic botany, becoming professor in 1901. He retired in 1919 with the title of emeritus professor, and acted as honorary curator of the Farlow Herbarium.

Such is the bare outline of the career of one whose work in mycology is classical. His first researches were on the rust *Gymnosporangium*, but he published an account of the entomogenous family Entomopthoreæ in 1888, which still remains one of the most important papers on the group. A few phytopathological reports appeared while he was at Connecticut, some of considerable interest. In 1890 he made his first contribution to our knowledge of the peculiar entomogenous fungi, the Laboulbeniaceæ, and it is with these that his name is chiefly associated, for from being almost unknown, they became, owing to Thaxter's enthusiasm, a group as well understood as any other and containing hundreds of genera and thousands of species.

Thaxter's method was to publish preliminary diagnoses of new genera and species and gather these together in monographs bearing the title "Contributions towards a Monograph of the Laboulbeniaceæ", which were illustrated with numerous plates of admirable drawings by the author. Part V. of the "Contributions" appeared this year, and he was busy preparing a sixth when he died. Some idea of the work entailed in the

description and figures may be gained from the fact that the five parts in all run to 1185 pages and 166 plates. Probably no mycologist, with the exception of Elias Fries, has ever been identified with a group to the extent that Thaxter was with the Laboulbeniaceæ. However, he did not restrict his observations to this fascinating group, but seemed to possess an almost unhuman *flair* for finding fungi which he himself called "new or peculiar", and described by him occasionally throughout his career. He was, moreover, the first to recognise the anomalous group Myxobacteriaceæ which have lately come into fashion.

Thaxter's association with Prof. W. G. Farlow at Harvard was an ideal one, and together they succeeded in building up a school of cryptogamic botany and herbarium which are without rival in any university. For a number of years Thaxter suffered from ill-health, but his letters were always cheerful, even when increasing trouble with cataract made it seem probable that he would be compelled to cease work. He was somewhat critical of some of the recent tendencies in applied mycology, but his criticisms were given from the fullness of his knowledge of the subject and not from a feeling of having been left behind.

In 1907, Thaxter succeeded Farlow as American editor of the *Annals of Botany*, Farlow having served since its beginning in 1887. His name was thus always prominently before British botanists. He received many distinctions; among others, he was a foreign member of the Linnean Society of London, honorary fellow of the Royal Society of Edinburgh, and honorary member of the British Mycological Society.

DR. CUTHBERT CHRISTY

NEWS has recently been received of the death on May 29, at sixty-eight years of age, of Dr. Cuthbert Christy, the well-known naturalist and explorer, who was engaged in scientific work for the Belgian Government in the Congo. It appears that, while in the Aka River region, he wounded a buffalo which turned and gored him, inflicting fatal injuries. He had for many years been collecting for the British Museum (Natural History), and his collections, notably those from Lakes Nyasa and Tanganyika, have proved to be of quite exceptional importance.

Dr. Christy was the son of Robert Christy of Chelmsford, and was educated at Scarborough and the University of Edinburgh, where he proceeded to take a medical degree and was appointed Mackenzie bursar in anatomy. His first travels abroad started in 1892, when for three years he travelled throughout a large part of South America and the West Indies. Some years later he was appointed Medical Officer of the 2nd Battalion West African Field Force in Northern Nigeria, and afterwards took on the duties of medical officer in India in the Bombay Plague Laboratory. In 1902 he served on the first Sleeping Sickness Commission in Africa, and at a later date was a member of the Liverpool School of Tropical Medicine Sleeping Sickness Expedition to the Congo, and of that organised by the Sudan Government.

Dr. Christy's intimate knowledge of native life in health and disease, and his explorations in many fields, are revealed to some extent in several published works and reports, among them being "Big Game and Pygmies", "Mosquitoes and Malaria", and "The Birds of San Domingo". He was chairman of the International Commission appointed by the League of Nations to inquire into the existence of slavery and forced labour in Liberia; and the recommendations of the Commission were accepted by the Council of the League and the Liberian Government.

Between 1903 and 1910, Dr. Christy visited Ceylon and various parts of East and West Africa, all the time collecting such specimens for the Natural History Museum as came his way. From 1911 until 1914 he was engaged in scientific exploration work in the Congo, and during this period he obtained many specimens for the Museum collections.

Among the mammals collected during this period were an important collection from the neighbourhood of Avakubi, in which Dr. Christy obtained two rats new to science and a dormouse which was named after him, *Graphiurus christyi*. He also obtained specimens of many rare West African forms in the same collection, thus adding considerably to our knowledge of the distribution of these species.

During the War, in spite of official duties, Dr. Christy still continued to collect, and sent home a very fine collection of fish from Mesopotamia. After the War he conducted two very important expeditions, one to Lake Nyasa and one to Lake Tanganyika, where he collected a great quantity and variety of fishes. These collections have proved to be some of the most important that have ever been received by the Natural History Museum, and the number of new species already described is very great; in one genus alone the species have been multiplied by six since Dr. Christy's collection has been worked out. The work in connexion with these collections is still continuing and many new forms doubtless remain to be described.

Medical science has lost a very able man in the death of Dr. Christy, and zoological science has lost one of its keenest collectors and most painstaking observers.

MR. L. G. SUTTON

THE death of Mr. Leonard Goodhart Sutton, in his sixty-ninth year, took place somewhat suddenly at his residence, "Hillside", Reading, on June 13. Mr. Sutton was a grandson of the founder, and at the time of his death senior partner, of the world-famous firm of Sutton and Sons. He was educated at Wellington College, and later went to the Royal Agricultural College, Cirencester, where he became particularly interested in the botany of grasses, of which group of plants he had a wide and accurate knowledge. After leaving Cirencester, Mr. Sutton spent two years in Germany, devoting himself to the study of the methods of seed production. On returning to England he entered the firm as a

partner, and ultimately settled down to development and extension of the floricultural side of the firm's activities, his outlook and experience being afterwards enlarged by visits to California and South Africa.

Mr. Sutton had a keen, refined sense of the æsthetic and cultural merits of flowers in general, and possessed an unerring intuition of the charm of old favourites and the floricultural possibility of new introductions to the garden, such as the South African *Nemesia strumosa* and allied species, which may be arranged to provide a glorious display of colour almost throughout the year. Belonging to the old school of plant breeders, Mr. Sutton paid special attention to the observation of small differences and the repeated selection of these in the evolution of improved forms. He was, however, fully alive to the value of a knowledge of Mendelian laws of inheritance in the practical improvement of garden plants. He wrote very little, but his unpretentious little volume—an extension of a lecture delivered before the Royal Horticultural Society—on garden annuals, is a charming introduction to the beauty, variety, and cultivation of this gay group of plants for which he had such an intense love.

Mr. Sutton took an ardent interest in educational affairs, and at the time of his death was president of the Council of the University of Reading; his inspiring presence and sound judgment will be greatly missed.

WE regret to announce the following deaths:

Dr. Bedford Pierce, past president of the Psychiatry Section of the Royal Society of Medicine, on July 8, aged seventy years.

Sir Richard Threlfall, G.B.E., F.R.S., chairman of the Fuel Research Board, on July 10, aged seventy years.

News and Views

Colloidal Fuel

TOWARDS the end of the War, when the demands for oil for naval purposes exceeded available supplies, efforts were made in America to make the oil go further by admixture of pulverised coal to give a blend called 'colloidal fuel'. Coal is appreciably heavier than oil, and it is obviously essential to prevent segregation of the components when blended. According to the American patent literature, stable solutions were obtained by suitably grinding the coal and by the incorporation of a stabilising 'fixateur', for example, a soap solution or a lime rosin grease. Great publicity was given at the time to this work, and the advantages of such blends were recognised. The coal-oil blend was heavier than water, could be stored under water, and was therefore 'safe' to store, while its calorific value per gallon exceeded that of oil. The lower price of coal reduced the cost of the unit of heat in the oil. In spite of these advantages, when oil again became freely available 'colloidal fuel' passed into the background. The subject was discussed in the House of Commons on July 5, and Mr. Foot, Secretary for Mines, referred to the experimental work which has been carried out by the Cunard Steamship Co., Ltd. This Company has continued investigating the possibility of blending coal with oil, and one of its liners, the *Scythia*, has just made the round trip between Liverpool and New York with one boiler fired solely by 'colloidal fuel' containing 40 per cent of coal.

ACCORDING to a report in the *Times* of July 6, the technical staff of the Cunard Company is entirely satisfied with the performance of the fuel. The burners gave no trouble, the ship's deck was free from grit, and the blend retained its stability. No details have been disclosed as to the mode of preparation, but it is claimed that the blend will retain its stability for three months. 'Colloidal fuel' is of obvious importance to European coal-producing countries, and the importance increases as coal tends to cheapen. Authorities agree that for ocean liners and naval vessels, oil fuel has such advantages over lump coal that even price loses its importance. When coal is pulverised, it acquires some of the advantages of a fluid, but a ship is scarcely the place to manufacture fuel. If a satisfactory blend can be made ashore and taken on board by pumping, the position will be greatly improved. Clearly the problem deserves the closest investigation, and the studies of the Cunard Company may be contrasted with the futility of a deputation of coalowners begging the Government to compel the Admiralty to burn coal instead of oil. Much oil is also being used in land installations, and the fuel should be equally applicable for these.

Professional and Technical Workers in the Civil Service

THE tradition that professional and scientific men should be passed over by authority when the personnel of Royal Commissions and other public inquiries are under consideration is well established and has frequently been the subject of comment in these columns. Recently, however, this attitude towards the expert has expressed itself in a new form. It happens that in the negotiating machinery which deals with economic questions concerning the civil service as a whole the existence of the expert has been recognised, in the constitution of the National Whitley Council, by the formal inclusion of the Institution of Professional Civil Servants as one of the three representative groups of staff associations. Recently, as is generally known, negotiations have been proceeding between the Government and the staff associations through the medium of the National Whitley Council regarding the future of the bonus system in the civil service. At one stage in the negotiations the authorities desired to convey to the staff side of the National Council certain important alternative proposals dealing with the subject under discussion, and for this purpose

the permanent secretary of the Treasury thought it necessary to invite representatives of various sections of civil service opinion to an informal discussion.

WHILE informal discussions may serve a useful purpose, it is worth while asking why no representative was included of the professional and scientific interests in the civil service, of which the Institution is the accredited spokesman, although among those invited was the representative of at least one smaller body representative of non-technical interests. Official representations from the Institution were put aside on the ground that the conversations were 'informal', although the attempt was afterwards made to treat as negotiators the four individuals selected. We could have perhaps understood, even if we had deplored, this failure to acknowledge the existence of the specialist interest in the civil service, were it not for the fact that the Institution's position has already been recognised by its special direct representation on the National Council to which we have referred. It is a curious revelation of official psychology that it should be thought unnecessary to consult with this distinctive and, we claim, this essential element in the modern civil service, upon a major issue affecting specialists in common with other types of civil servants.

Taxes on Books in Australia

MR. LYONS' Government in Australia, "having given very earnest consideration to requests that the taxation burden on educational literature should be lightened", has, we learn from an announcement in the Melbourne *Argus* of June 3, granted certain exemptions which, though satisfactory so far as they go, are very meagre concessions compared with the case against a tax on books of any kind. Primage duty at port of entry will no longer be charged on books and periodicals imported by or for the State public libraries, the National Library at Canberra, and the libraries of the several universities. Hymn books, prayer books, and literature published by or issued under the authority of the League of Nations will also be admitted free; and so will historical records in print, picture, or manuscript imported by or for libraries. Unfortunately, the sales tax still remains.

Alleged Psychic Phenomena

IN a long letter to NATURE, Mr. Harry Price, the honorary director of the National Laboratory of Psychical Research, has commented upon the review of Dr. Osty's book, "Les Pouvoirs inconnus de l'esprit sur la matière", published in these columns on June 25. He states that both Mr. Malcolm and Mr. Lambert changed their views regarding the alleged psychic phenomena produced by Mr. Rudi Schneider, although Mr. Lambert, according to the letter quoted by Mr. Price, merely says that, in his opinion, there was no possibility of the *medium* having produced the phenomena fraudulently. It is clear that these later opinions were not based on personal observation but from reading the record of others. Again, Mr. Price dismisses, without apparently realising its relevance, the incident of the match-box, suggesting, as it does, the invasion of the séance room from without, suspected for so long by competent observers. Moreover, in upholding the genuineness of Mr. Schneider's phenomena, Mr. Price declares that the opinions quoted in the review were from persons who had *a priori* convictions that the mediumship was a fraud—a statement in support of which he offers no evidence and which is almost certainly contrary to fact.

Physics and Psychics

IN conclusion, Mr. Price emphasises his own views on the independent examination of mediums by remarking that it has been his practice to introduce them to men of science of repute in order to encourage independent investigation; and in this he claims some considerable success. It must be remarked, however, that the invitations issued by the late Dr. von Schrenck-Notzing, the late Dr. G. Geley, and by Mr. Price were not for the purpose of granting any true scientific inquiry. The persons invited were merely privileged spectators of phenomena produced under conditions over which they had little control and in circumstances where accuracy of observation was almost impossible. Mr. Price claims that the phenomena described by Dr. Osty have been duplicated by him with similar results, and that when Mr. Schneider is in London in September of this year he will be pleased to invite assistance from physicists. What is wanted, however, is not the mere presence of experts at the experiments of others in an atmosphere which, rightly or wrongly, cannot fail to arouse suspicion. It is an arrangement whereby the alleged influence at a distance, which, it is claimed, can be measured and detected by purely physical means, is so measured and examined by independent observers in their own laboratories, with their own apparatus, and under those conditions most favourable to accurate scrutiny.

Early Man in America

IT is a not infrequent occurrence in America for discoveries to be announced which, it is said, afford indubitable evidence of the existence of man on that continent in very early times. Usually this evidence takes the form of one or more stone implements associated with the bones of extinct mammals, such as an elephant, in deposits held to be Pleistocene and in conditions which are claimed to justify the conclusion that the implements and fossils are contemporary. Usually it appears on further investigation that it is either impossible to verify the exact position, relative or absolute, of the finds, or an application of the strict canon of evidence reveals some flaw which vitiates the conclusion. American palæontologists and archæologists, however, continue to examine with patient determination every claim that is reported, and at the same time to examine diligently areas in which the deposits are such as might well afford the evidence which is sought. One such area is the State of Nebraska, which, in view of its geographical relation to the glacial area of the ice age, is regarded by

American geologists as of great promise in this respect. Three discoveries have been reported in this State recently, according to Science Service of Washington, D.C. In two instances, students of the University of Nebraska have discovered flint implements in association with the bones of fossil bison under some sixteen feet of loess which, it is claimed, is earlier than the last glaciation. These two discoveries lie about sixty miles apart. The third discovery was near the town of Angus, where, it is claimed, a flint implement was found under the scapula of a mammoth. The sites have been visited by Dr. W. D. Strong, of the Bureau of American Ethnology, who regards the discoveries with very considerable reserve.

Antiquities from the Ancient East

ON July 11 two exhibitions of antiquities found in the course of excavations during the past season were opened in London, at University College, Gower Street, and at the British Museum. At University College, Sir Flinders Petrie has on exhibition the finds of the expedition of the British School of Archæology in Egypt at Tell el-Ajjul, the ancient Gaza. The antiquities from the Hyksos levels will give an added attraction to the exhibition in the estimation of the general public; but the real interest of the collection as a whole lies rather in its extent and completeness in range over Palestinian cultures from the copper age to the time of the eighteenth dynasty and later. A quantity of pottery from the Ægæan and Mycenæan civilisations, from Egypt, Cyprus, and elsewhere, indicates the importance of the site as an early meeting point of international lines of communication. Particularly to be noted among the exhibits are fine daggers of the copper age, alabaster vases of the eighteenth dynasty, and glass of the same period. Two finds to which attention has been directed in preliminary reports on the season's work—the group of battered vessels and gold and silver, associated with burnt bones, which seem to be of the nature of a comminatory offering, and the gold ornament of torc form for which Irish affinities have been suggested—will certainly attract notice. The exhibition will remain open for four weeks.

AT the British Museum the collection of antiquities yielded by the past season's excavations at Ur will remain on exhibition for a period of three months. The character of the work, although it was essential and might have proved of the greatest value scientifically, was not such as would be likely to afford spectacular results for exhibition purposes comparable with those of recent years. There is, however, a number of gold frontlets and beads and a striking terra-cotta figure of a god with a mitre of bull's horns in the best tradition of Ur. There are also a limestone statuette of the goddess Pa-Sag and a copper statuette of the same deity, the latter discovered in the pedestal of a limestone figure. These belong to the third dynasty. A steatite bowl of the same period shows the figures of five oxen as decoration. One of the most interesting items in the collection is the steatite stamp seal assigned to Mohenjo-daro as its place of origin, on which are engraved an Indian buffalo and an inscription in the script of the Indus valley. Mention must also be made of the collection of types of beads from about 4000 B.C. down to the Persian era of the fourth century B.C., and the collection of seal-impressions from various sources which, it is inferred, were once the property of a jewel collector at Ur.

The Freshwater Biological Association

THE annual general meeting of the Freshwater Biological Association of the British Empire was held on June 29, and Mr. Reginald Beddington was elected president. The Report for the year shows that the Association, which was established as the outcome of a discussion at the meeting of the British Association at Glasgow in 1928, has made considerable progress during the past year. Support has been received from the Development Commissioners, scientific societies, waterworks associations, fishery boards and angling associations, and many private individuals. The interests of anglers are very closely concerned with research into the conditions existing in fresh waters, but not as much help as was expected has been received from those directly interested in angling. In September the Association opened a laboratory on the shore of Lake Windermere, certain rooms in Wray Castle, a property owned by the National Trust, having been equipped for this purpose. There are two naturalists employed in research at the laboratory, and there is accommodation for visiting research workers. A number of workers from Great Britain and from abroad have already occupied tables in the laboratory. There is a launch for work on the lake, and this launch is fully equipped for hydro-biological research. In extending its programme of research the Council of the Association has felt the difficulty of a lack of funds. A special appeal is made to all who are interested in fresh waters to support the Association. The address of the honorary secretary is Mr. J. T. Saunders, Christ's College, Cambridge.

Photographic Copying by Contact

IN the early days of photography, the late Mr. J. H. Player invented a method of making full-sized copies of black and white print, drawings, etc., without the use of a camera or lens. The process, known as 'playertype', is easily worked and may sometimes be used with advantage. The drawing to be copied is taken to the dark room. A sheet of ordinary bromide paper, or a photographic plate, is placed with its sensitive surface in close contact with the drawing. The paper is then exposed for a short time to the light from any convenient ordinary source of white light of low power. The light passes through the paper and its sensitive coating, illuminating the drawing beneath. Less light is reflected back from the black lines of the drawing than from the white ground. Thus the total illumination of the sensitive coating opposite the black lines is less than that opposite the white ground. On developing the sensitive material a somewhat foggy negative is obtained. This negative can be used for

printing any number of photographic copies in the usual way. Recently this process has been revived by Messrs. Luminophor, Ltd., 27 Queen Victoria Street, London, E.C.4, who supply phosphorescent screens to replace the ordinary light source of the original 'playertype'. One of the screens must first be excited by exposure to daylight or to magnesium light. It is then placed upon the bromide paper and drawing and allowed to remain for some minutes. Subsequent operations are similar to those already described for 'playertype'. However, while these phosphorescent screens are sometimes convenient, they are costly and really quite unnecessary.

Beit Memorial Fellowships for Medical Research

The following elections have been made by the Trustees of the Beit Memorial Fellowships for Medical Research, the subject and place of research being indicated after the name:—*Senior Fellowship in Tropical Medicine* (£1000 a year, for one further year): Dr. E. Hindle, spirochætosis, with special reference to the causation of yellow fever. *Fourth Year Fellowships* (value £500 a year): Dr. C. L. Cope, excretion by the mammalian kidney of the glomerular dyestuffs and of the inert sugars believed to be excreted only by the glomeruli (Radcliffe Infirmary and Department of Biochemistry, Oxford); Margaret Honora Roscoe, to continue work on the vitamin B complex (Lister Institute of Preventive Medicine, London); Mr. K. A. C. Elliott, to complete work on peroxidases, and then to study tissue respiration from the point of view of carbon dioxide evolution (Sir William Dunn Institute of Biochemistry, Cambridge). *Junior Fellowships* (£400 a year): Dr. H. P. Himsworth, activation of insulin by a possible kinase and effect of diets of varying composition on diabetic patients (University College Hospital Medical School, London); Mr. N. R. Lawrie, biochemical investigation of the nutritional requirements of Protozoa and the study of patients with abnormal metabolism of sulphur-containing compounds (Sir William Dunn Institute of Biochemistry, Cambridge, and Addenbrooke's Hospital, Cambridge); Dr. D. H. Williams, carbohydrate metabolism, particularly the storage of liver glycogen in experimental animals (Department of Physiology, University College, London); Mr. D. W. W. Henderson, antibacterial mechanisms in prophylaxis and therapy of tetanus; cultivation of the viruses of louping ill and fowlpox (Lister Institute of Preventive Medicine, London); Dr. R. G. R. West, neurological mechanism of tetany and the pharmacology of curare (Physiological Department, St. Bartholomew's Hospital Medical School); Dr. R. Gaddie, intermediate carbohydrate metabolism of isolated frog's heart; mode of action of insulin in the animal body (Departments of Medical Chemistry and Materia Medica, University of Edinburgh); Mr. F. G. Young, storage of carbohydrate by the liver in experimental animals (Departments of Physiology at University College, London, and at the University of Aberdeen); Dr. J. M. Robson, hormonic factors responsible for the maintenance of pregnancy and onset of parturition (Institute of Animal Genetics, Edinburgh).

Beit Fellowships for Scientific Research

BEIT Fellowships for Scientific Research of the annual value of £240 and tenable at the Imperial College of Science, South Kensington, have been awarded to Mr. R. M. Shackleton (University of Liverpool and Imperial College), for research on the geology of the area about Moel Hebog; Mr. E. G. Jones (University College, Nottingham, and the Einstein Institute, Astrophysics Observatory, Potsdam), for research on hyperfine structure of spectral lines; Mr. R. L. Rosenberg (Universities of Cape Town and Berlin), for theoretical investigations in topics connected with quantum mechanics; Dr. O. B. Westcott (University College, Exeter), for research on the electro-deposition of tin with the view of establishing the precise conditions under which crystalline deposits may be obtained and avoiding the unsatisfactory spongy deposits which result from present processes. In addition, the fellowships awarded a year ago to Mr. W. H. Wheeler, for research in chemical technology, and Mr. J. I. Armstrong, for plant physiology research, have been extended for a second year.

Cancer Research

THE ninth annual report of the British Empire Cancer Campaign, presented at the annual meeting on July 11, illustrates the diversity of ways in which the cancer problem is being approached—observational, experimental, and clinical. The best discovery announced is the identification by the Cancer Hospital Research Institute of a pure chemical substance—1 : 2 : 5 : 6 - dibenzanthracene — which causes epithelial and connective tissue tumours in the great majority of treated animals. Some progress has also been made in perfecting an antiserum which will cure mouse tumours, but it remains questionable whether there is much prospect of applying the method successfully to human cases. The account of cancer as a gene mutation lacks something in historical perspective: it does no more than translate Boveri's hypothesis into modern terminology.

Wool Production in the Empire

THE Wool Industries Research Association and the Empire Marketing Board are to be congratulated on their joint effort to make a survey of the conditions of wool production throughout the British Empire, particularly from the point of view of assessing the factors, economic and biological, which play a part in controlling production in different areas. The report, the result of a three years' survey by J. E. Nichols, has just appeared under the title "A Study of Empire Wool Production" (Wool Industries Research Association, Leeds; 5s. net). In 148 pages it would be impossible to follow all the vagaries of wool production, but Mr. Nichols has made the most of his space by discussing three main aspects: the conditions under which wool production occurs, and this includes geographical conditions as well as the conditions of the fleece itself; the phases of wool production in the Empire, which means that the breeds of sheep, the qualities of the wools, the factors affecting the industry, are discussed for each country

in turn; and finally, Part 3 "constitutes an attempt to analyse the concept of wool improvement and an examination of methods of development of its production".

Academy of Natural Sciences of Philadelphia

IN an attractive *Year Book* for 1931, it is recorded that the 120th year of the Academy's existence was signalised by notable activities in many directions. In each of the three major fields—laboratory studies, expeditions, and museum exhibits—the year set new records for this oldest institution of its kind in America. During the year, twenty-two expeditions for organised collecting, sponsored wholly or in part by the Academy, obtained material for study or exhibits from North, South, and Central America, as well as from Asia and Africa, and covered more than 175,000 miles during their quests. One result is seen in the addition of more than 8700 new specimens of vertebrates alone to the study collections. That the museum side of the Academy's activities arouses growing interest is indicated by the increased number of visitors, which for the first time exceeded 100,000; but the photographs of the cases of small mammals in the North American hall give an impression of the grouping of incongruous species, which suggests that here there is still room for the development of artistic natural groups. It is announced in *Science* that the following have recently been elected correspondents of the Academy: Prof. L. H. Bailey, Dr. H. B. Bigelow, Prof. R. A. Daly, Dr. Ludwig Diels, Prof. J. Stanley Gardiner, Prof. Hugo Glück, Prof. W. D. Gregory, Prof. A. S. Hitchcock, A. Lutz, Prof. E. de Margerie, Prof. E. D. Merrill, E. W. Nelson, Prof. A. C. Seward, Dr. E. O. Ulrich, and Mr. B. P. Uvarov.

Eradication of Slugs and Snails

SLUGS and snails are some of the most widespread pests on farms and in gardens, but owing to their nocturnal habits and their capacity for excreting slime which enables them to get rid of irritating substances, they are very difficult to control. Their natural enemies, for example, various birds, toads, moles, and predaceous ground beetles, are insufficient to keep their numbers in check, and special means of control are often necessary. Though no means of absolute eradication of these pests is as yet known, the Ministry of Agriculture has published an *Advisory Leaflet* (No. 115), in which various check measures are described. In gardens, large numbers of slugs may be caught by means of traps consisting of cut potatoes, orange skins, cabbage leaves, tiles, boards, or sacking placed on the soil, for the animals will collect under them for shelter during the day. Hand collecting at dusk is also recommended. For larger areas, the use of certain chemicals with a corrosive or toxic action is advised. Quicklime or salt are destructive if they come in contact with the upper part of the slugs' bodies, and applications made at night (or two or three times during the same night, if possible) should prove useful. Barriers of repellent material such as soot, washing soda, 'dry Bordeaux', etc., are often successful, and recent trials have shown that 1 part creosote mixed with 100 parts of precipitated chalk placed around each plant at the rate of ½ oz. per plant is worth further trial.

Forest Fires

LEAFLET No. 9 issued by the Forestry Commission (H.M.S.O., 1931) deals with this subject, which is of growing importance in Great Britain. The type of forests most subject is the coniferous; outside tropical regions, fires in forests of broad-leaved trees are less dangerous. Woodland fires are not new in Great Britain, and in dry seasons they have been only too prevalent on commons. The Forestry Commission attributes twenty-five per cent of the fires occurring nowadays in its new forests to carelessness on the part of picnickers and wayfarers. Since the advent of the Forestry Commission and the large coniferous planting campaign which has been inaugurated under its auspices during the past twelve years, the forest fire problem has entered upon a new phase. The most common form of danger is the surface or ground fire, burning dead leaves, etc., on the forest floor. The stem and crown fire is rarer in Great Britain. Newly planted areas are in greatest danger during March and April, although a dry February produces the same conditions. During a summer drought the danger reappears. The grass, under the influence of dry east winds or a summer drought, becomes as dry as tinder, and a cast-away lighted match or burning cigarette-end will start a fire which will quickly get out of control of the perpetrator of the act. After pointing out the various dangers to plantations situated under differing conditions, the leaflet deals with various methods of control, such as lay-out of plantations, order of felling, removal of debris, patrolling, equipment of tool depots, clearance of growth outside plantations, importance of immediate action, counter-firing, and the measures to be taken after the outbreak.

The Making of Factories

IN *Helios* for March 20, the export journal of the *Zeitschrift für die Elektrotechnik*, there is an interesting account of the Gladitz Company of Berlin, the main business of which is to instal and equip completely in every detail lamp-making factories. Any one willing to start a factory for electric lamps need have no technical knowledge of the subject. For example, a capitalist in Mexico City recently ordered a modern lamp-making factory. The plans for the building were prepared by the company and it was erected under the supervision of a local architect. During this time the necessary equipment, down to the smallest detail, was made in Germany. German engineers then went to Mexico and installed the machinery. They took with them a staff of male and female workers. The Mexican labourers, both men and women, were instructed by this staff. In a year's time the instructors had all left, the only German remaining being the technical manager. Three months after the building was erected, lamps began to be manufactured, and the production is now 16,000 per day. The contract comprises the supply of all machines and accessories, the factory organisa-

tion, the instruction of local labour, continuous control, and consultation. The Gladitz Company has already installed complete factories in many countries of the world, with departments for wire treating, glass treating, exhausting, and finishing the lamps. It is interesting to notice that several of these factories are now being controlled by the large lamp companies. The company considers that this is a compliment to the work turned out by the factories it has started. It is busy at present in developing practical manufacturing methods of making neon signs for manufacturing purposes.

Precautions in Use of Electro-Medical Apparatus

SERIOUS accidents from the use of electro-medical apparatus have so far been few in number, but the risk is likely to increase in the future, owing to more extended use of such appliances and also to the tendency to make use of the standard alternating current of 230 volts. Industrial experience shows that serious shock is more likely to result from alternating than from direct currents of the same voltage. The Ministry of Health has therefore issued a Memorandum (Mem. 161 Med.) with covering Circular (No. 1267) directing attention to precautions that ought to be taken in the use of electro-medical appliances, adoption of which should go far to minimise the risks involved.

Researches from the University of Sydney

The published work of members of the University of Sydney is made more generally available by the issue of collected reprints, which are now classified in twelve series, according to the nature of the research. We have recently received vol. 1, Reprints Nos. 18-24, in Series I. (Agricultural and Veterinary Science), vol. 1, Reprints Nos. 22-32, in Series VIII. (Medical Sciences—Clinical), and vol. 3, Reprints Nos. 1-19, in Series IX. (Medical Sciences—Non-Clinical). Most of the papers have been published within the last two years; a few are of less recent date. Most, but not all, were originally published in Australian journals. The range of subjects dealt with in each volume is wide, and indicates that an active spirit of research animates Australian scientific workers.

Hawaiian Volcano Observatory

WE regret to learn that, from July 1, the annual fund allotted to volcanology through the U.S. Geological Survey has been reduced from 35,000 to 15,000 dollars. Most of this sum is required for the work of the Hawaiian Volcano Observatory, and one of the first results of the reduction is that the weekly *Volcano Letter*, first issued in 1925, is to be replaced by a monthly leaflet. There will be no suspension of the research work, though the staffs at all the stations, in Hawaii, California, and Alaska, will be reduced.

Announcements

THE fifteenth Faraday Lecture of the Chemical Society will be delivered by Prof. P. Debye, of Leipzig, on March 29, 1933.

DR. H. R. MILL, who during his long association with the Royal Geographical Society has been actively engaged in the promotion and preparation of the polar expeditions of the past forty years or so, has been appointed by the King of Norway a Commander (2nd Class) of the Order of St. Olav, for his services to Norwegian arctic explorers. This order has previously been conferred upon Sir Clements Markham, Sir Ernest Shackleton, and Sir John Scott Keltie.

MRS. BOWEN, Titcomb Manor, Kintbury, Berks, informs us that she has fifteen bound volumes of NATURE, namely, vol. 45 to vol. 60, extending from Nov. 1891 to Oct. 1899, with the exception of vol. 54, which she generously offers to present to a suitable college, institute, or scientific worker, in need of them, upon payment of carriage. Communications should be sent direct to Mrs. Bowen at the above address.

A SPECIAL volume (vol. 9) of the *Australian Journal of Experimental Biology and Medical Science* has been issued as a memento of the late Prof. Brailsford Robertson, who founded the *Journal* and, until his death in January 1930, was its chief editor. The volume contains a biographical account of his scientific work, a bibliography of his writings, and nineteen papers specially contributed by his former colleagues and pupils, who are all acknowledged authorities on the subjects on which they write. The volume forms a unique and interesting collection of papers on those biochemical aspects of biological science to which the late Prof. Robertson during his lifetime made such notable contributions, both directly by his own individual work and indirectly by his inspiring influence on a wide circle of colleagues and pupils.

THE annual Report of the Governing Body of the Lister Institute of Preventive Medicine, recently issued, announces that Prof. William Bulloch has been elected chairman of the governing body, in succession to the late Sir David Bruce. An excellent survey of the numerous researches carried out by workers at the Institute is presented. The National Collection of Type Cultures, housed at the Institute, has had two hundred cultures added, and has distributed more than five thousand cultures, during the year.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant lecturer in zoology at the University of Birmingham—The Secretary (July 17). A lecturer in electrical engineering and physics at the Borough Polytechnic, Borough Road, London, S.E.1—The Principal (July 18). A principal of the College, and a headmaster of the College Secondary School, Swindon—The Director of Education, Education Office, Clarence Street, Swindon (July 21). A principal of the new Technical School, Hong-Kong—The Secretary (SIR/CA), Board of Education, Whitehall, London, S.W.1, or, for Scottish applicants, The Secretary, Scottish Education Department, Whitehall, London, S.W.1 (July 23). A lecturer in zoology at University College, Nottingham—The Registrar (July 30). A demonstrator in biology at Guy's Hospital Medical School, London Bridge, S.E.1—The Dean (Aug. 5).

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Oxygen Affinity of Chlorocruorin

CHLOROCRUORIN is the respiratory pigment in the blood of certain polychæte worms. Working in the laboratory of Dr. R. Wurmser in Paris, I have investigated the oxygen affinity of the specific chlorocruorin of *Spirographis spallanzanii*. The blood was diluted to approximately 6 parts in 1000 parts of 0·6 *M* phosphate buffers. In each experiment, 3 c.c. of the diluted blood was placed in a 300 c.c. glass saturator, to one end of which a small trough with parallel glass faces 2 cm. apart was attached. The oxygen pressure in the saturator was varied by measured amounts, and the solution equilibrated at

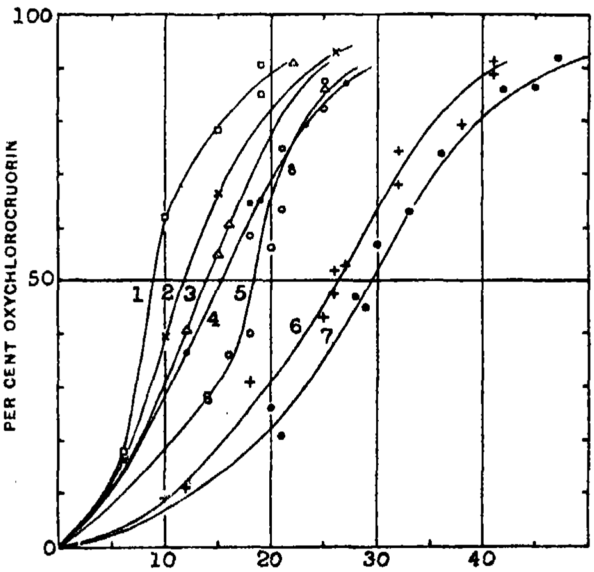


FIG. 1.—Oxidation dissociation curves of chlorocruorin. 1, *p*H 8·0, 10°; 2, *p*H 8·2, 20°; 3, *p*H 8·0, 20°; 4, *p*H 8·0, 26°; 5, *p*H 7·7, 10°; 6, *p*H 7·7, 20°; 7, *p*H 7·35, 26°.

each oxygen pressure by rotating the saturator horizontally in a thermostat. The saturator was then placed vertically with its trough in the course of the light beam of a spectrophotometer. The relative concentrations of oxy- and reduced chlorocruorin were obtained by measuring the light absorption at the wave-lengths in the visible region of the spectrum (604·5 and 580·5 mμ) where there is the greatest difference between the oxidised and reduced pigment.[1]

The results obtained are shown in Fig. 1. The *p*H limits are dictated by the fact that chlorocruorin is unstable above *p*H 8·5 and below *p*H 7·0. Both hydrogen ion concentration and temperature affect the oxygen affinity of chlorocruorin in a similar manner to mammalian hæmoglobin. The temperature coefficients (Q_{10}) of the reaction between chlorocruorin and oxygen (in the buffer solutions used), calculated from the oxygen pressures corresponding to 50 per cent saturation, are 1·6 at *p*H 8·0 and 1·5 at *p*H 7·7. Human whole blood at 38° is 50 per cent saturated with oxygen at an oxygen pressure of 29 mm. Hg, in presence of 40 mm. CO_2.[2] The same is seen to be true for diluted *Spirographis* blood at 26° and *p*H 7·35. The oxygen affinity of chlorocruorin at the temperatures at which the animal lives is, therefore, of the same order of magnitude as that of hæmoglobin in the human body.

The limiting temperatures studied, 10° and 26°, were chosen because the former is that of the winter sea in Brittany, the latter that of the summer sea at Algiers. These are extremes in the habitat of *S. spallanzanii*. It seems probable that the temperature effect on the oxygen dissociation curve is one of the limiting factors in the geographical distribution of poikilothermal animals having respiratory pigments. At too high a temperature the oxygen affinity of the chlorocruorin of *S. spallanzanii* would be so much diminished that there would be an insufficient difference in oxygen pressure between blood and tissues for the latter to receive oxygen at a rate necessary to maintain life.

Raman Spectrum of Nitrous Oxide

WE have photographed the Raman spectrum of nitrous oxide with a four-prism glass spectrograph having a camera lens of diameter 5 cm. and focal length 70 cm. The gas was at a pressure of 30 atmospheres and was illuminated with four 32 cm. long mercury lamps, container and lamps being surrounded by a reflector of suitable shape. The exposure time was 14 days, the spectrograph being, of course, enclosed in a thermostat. Average values of the frequency shifts obtained are listed in the first column of the accompanying table. In the third column are stated the transitions to which the Raman lines are ascribed, the quantum numbers V_1, V_2, V_3, and *l*, introduced by Dennison,[1] being used to designate the vibrational states of the molecule. The fourth column, finally, gives the values of the frequency shifts as computed from the recent infra-red absorption measurements of Plyler and Barker.[2]

Frequency (observed), cm.⁻¹.	Intensity.	Transition.	Frequency (computed), cm.⁻¹.
1170	weak	0000 ⟶ 0200	1167·3
1185	weak	0000 ⟶ 020 ± 2	1179
1260	weak, broad	Max. *PP*-branch	1256
1282	weak	010 ± 1 ⟶ 110 ± 1	1279
1286·5	very strong	0000 ⟶ 1000	1285·4
1315	weak, broad	Max. *RR*-branch	1314
2210	weak	010 ± 1 ⟶ 011 ± 1	2210·1
2223·2	strong	0000 ⟶ 0010	2224·1

The frequency shift of 1286·5 cm.$^{-1}$ was measured three times, being excited by the mercury lines 4047 A., 4078 A., and 4358 A. All the other frequency shifts were measured twice, being excited by 4047 A. and 4358 A. The values obtained for the two strong Raman shifts are probably correct to less than 1 cm.$^{-1}$. They are in fair agreement with the value 1282 cm^{-1}. found by Dickinson, Dillon, and Rasetti,[3] and the values 1283 cm.$^{-1}$ and 2226 cm.$^{-1}$ obtained by Bhagavantam.[4] The ratio between the intensities of the two strong lines may well be 10 to 1, as stated by Bhagavantam. However, with lines so far apart, it is impossible to make a really quantitative estimate of the intensities by mere visual inspection of the plate.

So far as we are aware, none of the weak lines has been observed before. The only lines about the reality of which there may be some doubt are the two

lines corresponding to the frequency shift 1282 cm.$^{-1}$. The difficulty of settling the reality of these lines exists because they lie close to the very strong lines corresponding to the shift 1286·5 cm.$^{-1}$, which lines appear to have an unsymmetrical intensity distribution, with the greatest broadening towards long wave-lengths.

The agreement between the frequency shifts observed in the Raman spectrum and those computed from Plyler and Barker's infra-red measurements is very good, and hence the interpretation given in the third column of the table seems scarcely open to doubt. While all the other Raman frequencies are interpreted as Q-branches, the broad lines having shifts of 1260 cm.$^{-1}$ and 1315 cm.$^{-1}$ undoubtedly represent the maxima of PP- and RR-branches. From their separation from the Q-branch at 1286·5 cm.$^{-1}$, we obtain the value of 61×10^{-40} gm. cm.^{2} for the moment of inertia of the molecule, in good agreement with Plyler and Barker's value $59{\cdot}4 \times 10^{-40}$. It is an interesting fact, also found with liquid carbon disulphide [5] and in perfect accord with the selection rules of Placzek,[6] that the transitions $0000 \rightarrow 010 \pm 1$ do not occur in the Raman spectrum, while the 'overtones' $0000 \rightarrow 0200$ and $0000 \rightarrow 020 \pm 2$ occur, although with low intensity. Our results strongly support the conclusion that the nuclei in the nitrous oxide molecule are linearly and unsymmetrically arranged.

One of us (J. R. N.) is indebted to the John Simon Guggenheim Memorial Foundation for the grant of a fellowship.

Dielectric Constant of Liquid and Solid Nitrobenzene

THE change of the dielectric constant of nitrobenzene with temperature was examined by J. Mazur,[1] who discovered that the value of the dielectric constant in the liquid phase drops abruptly from 38·15 at 9·6° to 11·82 at 7·7°. M. Wolfke and J. Mazur [2] try to explain this behaviour by the change of the structure of the molecule at the temperature of 9·6°, which temperature is said to separate from each other two modifications of nitrobenzene. In order to verify this, I have carried out at different temperatures measurements of the electric polarisation of diluted solutions of nitrobenzene in hexane. The results of these investigations, which will be dealt with in a special publication, show *inter alia* that the nitrobenzene molecule when passing the point 9·6° does not suffer a change of either electric moment or polarising power; [3] moreover, no such change occurs at any temperature between − 4° and + 30°.

I therefore determined to repeat the measurements of J. Mazur. I have investigated the dielectric constant of nitrobenzene in the temperature interval − 3·70 and + 50°. The nitrobenzene was specially

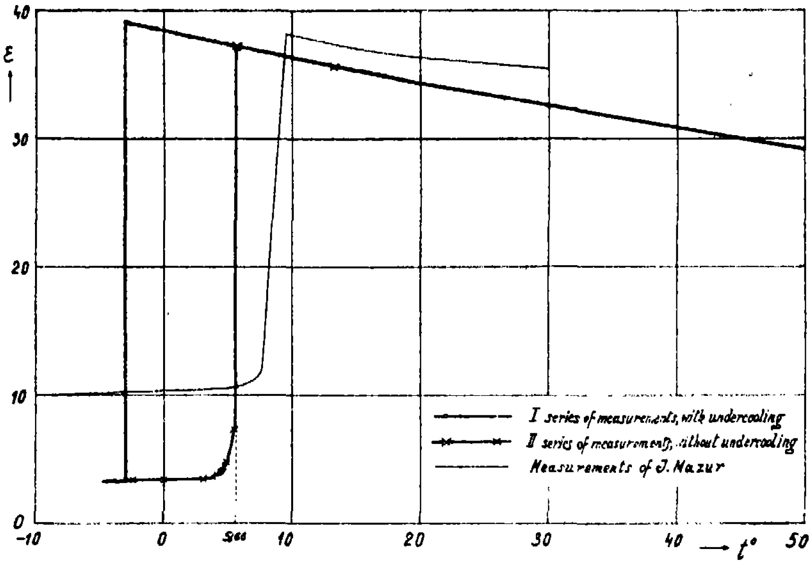

FIG. 1.

purified, for example, by repeated distillation and crystallisation, and dried by bubbling through it for several hours dried and carbon dioxide free air. The condenser was made of thermometric glass and platinum. The temperature was measured outside the condenser (in the oil bath) as well as inside. The results are shown in Fig. 1, and are quite inconsistent with those obtained by J. Mazur. The curve showing the change of dielectric constant with temperature does not show any peculiar point at the temperature of 9·6°. On the other hand, a quite abrupt decrease of the dielectric constant takes place at the freezing of nitrobenzene. This can occur at any temperature below the freezing point (+ 5·66°) provided the nitrobenzene is undercooled (first series of measurements), or at 5·66° without undercooling (second series of measurements). In the latter case, the dielectric constant drops abruptly from 37·25 to 7·36, after which it rapidly decreases to 3·44 at 0°.

Similarly, the density-temperature curve of nitrobenzene shows no inflexion at 9·6°, as found by Mazur,[4] and, therefore, the electric polarisation of liquid nitrobenzene shows no abnormalities down to the freezing point.*

The discrepancy between Dr. Mazur's results and mine are, I think, due, as Prof. Wolfke has suggested to me, first to the method of purifying and the degree of purity of this unusually capricious substance, and, secondly, it may be caused by some hitherto and as yet unknown conditions of obtaining nitrobenzene II, which conditions have been observed by some investigators [5] but not by others.

The Connexion between the Eötvös Magnitudes

IN the problem of locating subterranean anomalies of density, the Eötvös balance measures two quantities, the horizontal gravity gradient and the difference between the principal curvatures of the level surface at the point of observation. In the two-dimensional case these reduce to U_{xz} and $-U_{xx}$, denoted by $G(x)$ and $K(x)$ respectively. In all treatments of the subject which I have seen $G(x)$ and $K(x)$ appear to be considered independent of one another. It can be shown, however, that there is a one-to-one relation between the two functions, namely, that they are conjugate trigonometrical integrals of one another;[1] in fact:

$$G(x) = \frac{1}{\pi}\int_0^{\infty} d\alpha \int_{-\infty}^{+\infty} K(t) \sin \alpha(t-x)dt$$

and $$K(x) = -\frac{1}{\pi}\int_0^{\infty} d\alpha \int_{-\infty}^{+\infty} G(t) \sin \alpha(t-x)dt,$$

or,

$$G(x) = \frac{1}{\pi}\int_0^{\infty}\frac{K(x+t)-K(x-t)}{t}dt = \frac{1}{\pi}P\int_{-\infty}^{+\infty}\frac{K(t)}{t-x}dt$$

and

$$K(x) = -\frac{1}{\pi}\int_0^{\infty}\frac{G(x+t)-G(x-t)}{t}dt = -\frac{1}{\pi}P\int_{-\infty}^{+\infty}\frac{G(t)}{t-x}dt$$

where P denotes the principal part of the subsequent integral.

The second of these pairs of formulæ in particular enables one of the quantities to be obtained from the other, whether given in functional form or as a series of observations.

These results depend solely on the density anomalies lying all on the same side of Ox; which is, of course, the usual thing, the observations being made along the surface of the ground. They do not depend on the density changes being either continuous or discontinuous.

In the recent experimental survey in Australia[2] it is stated that the gradiometer, which only measures $G(x)$, is more satisfactory from a practical point of view than the torsion balance; it appears now that the latter instrument provides no further information than the former, so far as two-dimensional structures are concerned, since the measurement of $K(x)$ as well as $G(x)$ is redundant, or is only a check.

Swarming of Collembola in England

A RECENT letter in NATURE[1] directed attention to instances of swarming of certain species of Collembola. It was stated that "In most . . . cases . . . (if not all) the factor producing this phenomenon would seem to be the relative abundance of the food supply". In another instance it was suggested that "migration *may* account for swarming".

While in agreement with the first suggestion as a possible explanation of this swarming habit, certain observations made from time to time during studies on this order of insects might assist in carrying the subject a stage further. In September 1928 I examined, by means of a binocular microscope, the habits of individuals in a swarm of *Podura aquatica*, L. I was at first surprised at the number of head-capsules of adults which could be seen in the colonies; each head-capsule was completely devoid of all save the merest traces of the body. Observations revealed the fact that under these conditions the Collembola were carnivorous, and even cannibalistic, in habit. Individuals could be seen vigorously attacking other members of the swarm; the point of attack was evident, in some cases, by a drop of body fluid which exuded. During an attack the victim struggled and fought with mouth-parts and tarsal claws, but was gradually overpowered. When it succumbed, several other members of the swarm quickly collected around its mutilated body and devoured it, until the head-capsule alone remained. This habit appeared not only to provide food for the support and development of the colonies but also was a factor in keeping the small groups of the Collembola together while they fed, collectively, on the scattered dead bodies. Individuals about to moult proved ready prey for the more active members of the swarm.

A similar observation was recorded to a lesser extent among *Hypogastrura* spp. The swarming of *Sminthurus viridis*, Lubb.—a species which is mainly phytophagous in habit—has not been observed, but it has been a common experience, in heavily infested fields, to find that this species will readily congregate and devour specimens that had recently died.

I am not aware of any reference to this interesting habit among Collembola, and this no doubt explains why the observed species can remain congregated in swarms for long periods in such barren sites as surface water in cart ruts, bare stones, and even on tap water in glass dishes.

A factor which undoubtedly affects this swarming habit is humidity. It has been shown[2] that species of Collembola, particularly atracheate forms, require a saturated atmosphere to survive any length of time. Individuals, therefore, tend to congregate in local environments where these conditions are provided. Species which hibernate in the egg stage (*Sminthurus viridis*, *Bourletiella hortensis*, *B. lutea*, etc.) attain enormous numbers when temperature and humidity favour hatching; the movement of the young Collembola is then influenced by humidity. Such was the case[3] of *Bourletiella hortensis*, Fitch., which swarmed over the mangold field during the early morning when the soil was moist, but later in the day moved below soil-level, except when near plants which they had damaged. In this latter case the point at which plants' juices exuded provided both food and favourable humidity, hence this species swarmed in such sites.

The Rearing of *Hæmatopota pluvialis*, Linné (Cleg, Tabanidæ) under Controlled Experimental Conditions

DESPITE the potential or actual importance of blood-sucking insects in the transmission of pathogenic micro-organisms, investigation of the life-histories of the European species of the Tabanidæ, including that of the cleg, the most common of our palæarctic species, has been comparatively neglected. Hitherto the number of larval stages has not been ascertained in any European tabanid species, and for the rest this has been determined only in one bivoltine North American species[1] and in five trivoltine Indian species.[2]

In our experiments, which commenced in 1930, we have succeeded in inducing females previously fed on human or rabbit hosts to deposit typical tabanid egg-masses in the laboratory. In individual cases females have oviposited twice, the two acts of oviposition being separated by an interval during which a second

blood meal was taken. There is also evidence that a third oviposition may occur. The fact that two or more acts of oviposition can occur separated by intervals when another host is attacked, is of prime significance relative to the biological transmission of micro-organisms from one host to another.

On emerging from the eggs after an incubation period of about ten days, the first larval instars were isolated in a moist sand medium in small glass vials and reared to maturity under conditions identical for all. The number of ecdyses varied from 7 to 9, the last being that preceding pupation, and they were distributed over one or two years. Individuals reared from the same batch of eggs required either one or two years to complete their development, and it may be safely concluded that *H. pluvialis* is heterozygous for univoltine or demivoltine characters. This conclusion is corroborated by the results of a series of experimental rearings now being carried through at a constant temperature of 70° F. Whilst increased temperatures induced a decided increase in the initial rate of metabolism, as expressed in the more rapid growth of the early instars and decrease in the duration of the early stadia, they did not essentially alter the characteristic type of development. That differential development of palæarctic Tabanidæ resulting in life-histories extending over one or two years is not an unusual phenomenon, was abundantly evident in our investigations [3] of Canadian species, and appears to be genetic in its origin.

In order to obviate the risk of overlooking any individual ecdysis—which may readily occur in the case of the earlier ones—a series of measurements of a standard skeletal structure was made in each exuvium recovered. The paired tentorial rods of the head capsule were selected for this purpose and have proved invaluable in checking our observations. Counts of the number of pedunculate bodies in Graber's organ have also proved useful in this respect. Thus in *H. pluvialis* there are twice as many pedunculate bodies for any particular instar as the number which designates that instar. Contrary to what occurs in many other Tabanidæ, there is no elimination of pedunculate bodies to the exterior during larval development.

The detailed results of our investigations will be published later.

Origin of Insects from Crustacea

WHILE agreeing with the substance of Dr. R. J. Tillyard's remarks on the above subject,[1] it may be pointed out that certain observations upon the development of the coxal styles of the Machilidæ are to be found in a paper by R. Heymons published so long ago as 1906. In this communication, entitled "Ueber die ersten Jügendformen von Machilis",[2] it is mentioned that the styles in association with the thoracic coxæ of *Machilis* are not present in the young stages, and, in fact, are only discernible when the insect is in its third stage of development. This agrees with Dr. Tillyard's observations in which he points out that, in the Australian *Allomachilis*, the coxal styles are wanting in the first and second instars, and that it is only in the later instars that these organs become evident.

Dr. Tillyard also mentions that these problematical structures are devoid of muscles, and this fact, together with his conclusion relative to their being little more than secondarily developed spurs, are in accordance with views previously expressed by F. Silvestri [3] and by R. E. Snodgrass.[4] The main points of Dr. Tillyard's letter, therefore, confirm the conclusions of those investigators mentioned.

Implementiferous Deposits of East Anglia and the Lower Thames Valley

A CLOSE examination of the implement-containing deposits of the Lower Thames Valley has led us to realise that they are to be correlated with certain others in East Anglia. During the course of our investigations we have observed that the Boyn Hill or '100-ft.' terrace, which at Hornchurch is cut in the Kimmeridgic Chalky Boulder-clay (2nd glacial phase), and at Dartford attains a surface-level of 137 feet above O.D., contains no pene-contemporaneous hand-axes of greater age than that of the St. Acheul 1 period; whilst the coarse, and usually unstratified, melt-water gravels which rest upon the Coombe Rock include derived Early Mousterian (Levallois) implements and tortoise-cores, in addition to artefacts of earlier epochs.

Our researches prove that the deposits of the Taplow or '50-ft.' terrace, which at Acton reach a surface-level of 100 feet above O.D., were formed after the deposition of the Coombe Rock (3rd glacial phase) which overwhelmed the Early Mousterian (Levallois) factory-site at Baker's Hole, Northfleet. We have noted that (1) the base of the gravel underlying the brickearths of the Taplow terrace is composed (as at Slades Green and elsewhere) of a *remanié* formed from the Coombe Rock and its associated melt-water gravels; (2) the Coombe Rock has been truncated by the deposits of the Taplow terrace at Belmont Castle, and between Slades Green and Stone, and elsewhere; and recently one of us (J. P. T. B.) has discovered between Northfleet and Swanscombe the high and steep-angled cliff which has been cut through the Coombe Rock and Chalk and against which the Taplow deposits have been banked. Here, in the basal gravel underlying the brickearth of the Taplow terrace, we have located a horizon characterised by an abundance of pene-contemporaneous implements of Middle Mousterian age together with derived artefacts and mammalian remains.

During the early part of the succeeding period of elevation which followed the maximum of the Taplow submergence, fluviatile and sub-aerial loams, characterised by the shell *Helicella striata* (Müll.), were formed, which sealed in occupation-floors of the Aurignacian epoch containing flint implements and pottery fragments. The ensuing or 4th glacial phase is represented by stony hill-wash containing 'rafts' of Coombe Rock and/or by the 'trail'; the former may be studied at Grays and Swanscombe, whilst the latter is well developed at Belmont Castle and at Slades Green, where it caps the Taplow deposits. The 'trail' never overlies the Low or '25-ft.' terrace.

The results, both archæological and geological, that we are obtaining will be fully described in November next before the Society of Antiquaries of London: if our views are correct, it follows that no implementiferous deposits earlier than those of the second inter-glacial period of East Anglia are present within

the valley of the Lower Thames, and that these deposits were laid down from Clactonian 2/Acheulian times onwards.

Confirmation of the Space-Group of Epsomite

ALTHOUGH orthorhombic magnesium sulphate heptahydrate (epsomite) has been the subject of two previous investigations,[1, 2] in neither case was a complete structure proposed. We commenced work on this substance in the hope of carrying the knowledge of its structure to a more complete stage. Due to unforeseen circumstances, however, the investigation has been interrupted, and it is uncertain when the study can be resumed. We have considered it of interest to report some of our results, since they agree with those already in the literature, and thus serve as a third check on the dimensions of the unit cell and on the space-group.

The crystals employed were small prisms having faces of the form {110} prominently developed. The apparatus consisted of a Shearer X-ray tube fitted with a copper target ($K_\alpha = 1{\cdot}54$ A.) and a Müller spectrograph.

The results obtained for the size of the unit cell and the number of molecules per cell compared with the data of Cardoso and of Westenbrink are as follows:

	Barnes and Hunter.	Cardoso.	Westenbrink.
a_0	11·94	11·91	11·89
b_0	12·03	12·02	12·01
c_0	$6{\cdot}86_5$	6·87	6·86
mol./cell	4	4	4

Oscillation photographs showed conclusively that {*h*00}, {0*k*0}, and {00*l*} are halved. This was based on the fact that reflections from the odd orders from 1 to 12, inclusive, for {*h*00} and {0*k*0}, and from 1 to 6, inclusive, for {00*l*} were missing. Higher orders than these were unattainable with the apparatus employed.

The only orthorhombic space-group with these halvings[3] is Q^4, which is that found by Cardoso and by Westenbrink. Since Q^4 is in the bisphenoidal class, the X-ray data lead to the same conclusion as to crystal class as that reached by the methods of crystallography.

Our results for the dimensions of the unit cell agree more closely with those found by Cardoso, which are those selected by Wyckoff for quotation in the second edition of the "Structure of Crystals". They were obtained experimentally from rotation photographs about each of the three axes. Westenbrink calculated the primitive translations along the *a* and *c* axes by assuming the crystallographic axial ratio ($a : b : c = 0{\cdot}9901 : 1 : 0{\cdot}5709$)[4] to be correct and measuring $\theta/2$ accurately for the second order reflection from {110}.

This work was carried out during the tenure by one of us (R. G. H.) of a bursary from the National Research Council of Canada.

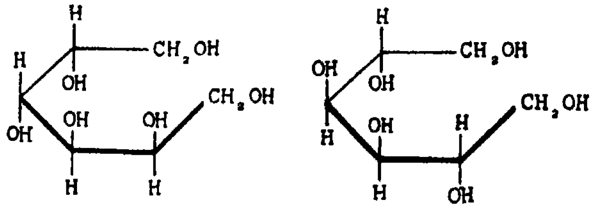
An X-Ray Study of Mannitol, Dulcitol, and Mannose

IN connexion with a paper under the above title,[1] Prof. W. N. Haworth has pointed out that the actual space formulæ of d-mannitol and i-dulcitol are:



d-Mannitol. i-Dulcitol.

On uncoiling these to give zigzag or slightly spiral chains of the nature suggested by the dimensions of the unit cells, the projections of the chains on a plane perpendicular to the plane of the zigzag become

```
         OH H  H OH                   OH OH H  H
         |  |  |  |                   |  |  |  |
HO·CH₂—C—C—C—C—CH₂OH       HO·CH₂—C—C—C—C—CH₂OH
         |  |  |  |                   |  |  |  |
         H OH OH H                    H  H OH OH
          d-Mannitol.                  i-Dulcitol.
```

This involves the alteration in position of two hydroxyl groups per molecule in the models illustrated in the paper. These alterations do not affect materially the fundamental features of the respective unit cells, but they introduce interesting possibilities which will be discussed in a separate paper.

I am very much indebted to Prof. Haworth for this correction.

Removal of Added Nitrogen from Grassland Soils

WORK has been in progress in these laboratories since 1929 on the available nitrogen of grassland soils, with especial reference to the soil ammonia, which in these soils preponderates in quantity and possibly also in importance over the nitrate. The work as a whole will not be completed for some time, but information has already been obtained which may be useful to other workers on the nitrogenous manuring of grassland.

An outstanding result is the speed with which nitrogen added to grassland soils, whether as ammonia or as nitrate, is removed. Observations made here and elsewhere on the rapid falling-off in the response to a single dressing of nitrogen on repeatedly mown plots have suggested that the added nitrogen could not remain for long in the soil, but its rate of removal by vigorously growing herbage has proved unexpectedly high.

A convenient measure of rate of removal is the interval required for three-quarters of the added nitrogen to disappear from the soil. With an early spring application (Feb. 18, 1930) of sulphate of ammonia on pasture, this interval was three weeks, and about the same time was required for a late autumn dressing (Dec. 6, 1929); these dressings were applied when the plant was probably almost dormant. For a heavy dressing of sulphate of ammonia applied in mid-spring, when vigorous growth was beginning, the interval required for disappearance of three-fourths of the added nitrogen was only seven days (Park Grass, meadow hay, 3¾ cwt. sulphate of ammonia per acre applied March 27, 1931). In late

spring (April 26, 1932), when growth was already vigorous, the corresponding interval for the same rate of application was two days. There was no appreciable accumulation of nitrate in the soil after any of these applications of sulphate of ammonia.

With nitrate of soda, as might have been expected, the disappearance of the added nitrogen was still more rapid: three-quarters of the nitrate added in an equivalent dressing (5 cwt.) on Park Grass had disappeared in about three days in mid-spring, and in late spring less than two days were required.

Without attempting to discuss these results—in particular, the question of what proportion of the nitrogen which disappears is obtained by the plant—they suggest certain practical applications. Evidently the short period during which added nitrogen remains in grassland soils greatly reduces the risk of loss by leaching-out of nitrates, except possibly during the winter months. Where grass is being repeatedly removed, as by mowing or grazing, the direct effect of added nitrogen might be expected to be of brief duration, since even if it is added as ammonia it does not remain long as a 'reserve' in the soil. This very rapid removal of added ammonia by vigorously growing grass—almost as rapid as the removal of nitrate, and a matter of days only—may be taken as a strong indication that in the soil, as well as in culture solutions, grass is able to assimilate ammonia directly without the need for previous nitrification. Further experiments are being made to examine this question.

Chain Reactions in Enzymatic Catalysis

Prof. J. B. S. Haldane has recently criticised the chain reaction theory [1] in the form in which it has been applied by Haber and Willstätter to biochemical processes.[2] One can scarcely deny the validity of Prof. Haldane's arguments, but his criticism is directed not so much against the chain reaction theory itself as against the particular chain *mechanism* proposed by Haber and Willstätter.

It has been suggested that a more satisfactory explanation of the experimental observations may be given by the *energy chain* mechanism.[3] According to this view, which is due to Christiansen,[4] molecules are capable of existing in an activated condition which they normally assume prior to reacting, and the chains are propagated by the transfer of energy from the products of an exothermal reaction to one of the reactants, which is thereby activated and in turn caused to react, *et seq.*

Prof. Willstätter has raised the objection that the activated molecules would at once lose their energy in collisions with the surrounding water molecules. This objection, which at first appears to be conclusive, loses much of its weight in the light of experimental evidence obtained by Gibson and Hinshelwood,[5] who have shown that the transfer of energy from an activated molecule is a *specific* process, so that the transfer of energy from organic molecules to water molecules may be taken as being comparatively slight.

Further evidence as to the specificity of energy-transfer has come from Perrin's work on fluorescence.[6] The simple observation that fluorescein fluoresces in aqueous solution shows that the activated fluorescein molecules do not easily give up their energy to the surrounding water molecules, but emit it more readily in the form of light.

As Prof. Haldane has pointed out in this connexion, in most intracellular oxidations much of the energy is not liberated directly as heat but is used up in coupled reactions. This is not easily explained on the Haber and Willstätter mechanism, but the idea of the specific transfer of vibrational energy from the products of an exothermal reaction to other molecules in the system makes these coupled reactions readily intelligible.

The Christiansen energy-chain also seems to give a more satisfactory explanation of the specificity of inhibition in enzyme reactions. On this view, inhibition, in so far as it may be attributed to the breaking of reaction chains, is due to the transfer of energy from an activated link-member of the chain to an inhibitor molecule, and this process should also be in some degree specific.

An Unpublished Letter of Lavoisier

The Science Library at Clifton College possesses an autograph letter of Lavoisier that I believe to be unpublished. Though it is of no scientific importance, any relic of so great a man deserves to be placed on record, and the following transcription may thus be of interest:

Je suis oblige mon cher Parent par le decret relatif a lemprunt forcé de presenter letat de mes possessions et l'evaluation du revenu doit etre faitte dapres la matrice des Rolles. Je vous serai en consequence tres oblige de faire faire dans chacune des paroisses ou je possede des biens un extrait de la matrice du rolle pour coqui me concerne avec l'evaluation du revenu. La loi ne donne que quinze jours pour faire les declarations aussy il ny a pas de tems a perdre. Vous concevis que le montant des impositions que je paye ne remplisoit pas mon objet, car en general limpost dans presques toutes les communautés est superieur a 'evaluation et puisque la loi a pris pour base cette evaluation il est juste que je proffite du benefice quelle m accorde.

Je ne scais si les haricots ont manque de vos cotes comme aux environs de Paris. Dans letat de denuement ou nous serons cet hiver a Paris pour les comestibles, il nous serait fort important que vous nous envoyassiez les haricots de redevance qui me sont dus.

Il y a bien long tems que je n'ay recu de vos nouvelles mais je concois que vous devez etre tres occupe relativement aux requisitions qui ont ete faittes.

Je vous renouvelle mon cher Parent lassurance de mon inviolable attachement.

Le 18 jt 1793 lan 2e de la republique une et indivisible.

Lavoisier.

The letter is addressed to Citoyen Parisis fils, at Villers-Cotterets, where Lavoisier's paternal ancestors were established as early as the beginning of the seventeenth century. Charles-Antoine Parisis was a distant relative of Lavoisier by marriage, having married Antoinette-Françoise Lavoisier, second cousin of Lavoisier's father, Jean-Antoine [Grimaux, *Lavoisier*, Paris, 1888, p. 326].

Inheritance of Milking Capacity

Now that Mr. Edwards[1] has made the first point of his original letter clear, his criticism is one which has already been suggested, and discussed, by myself. If this criticism were invariably valid, it should also hold good as regards butter-fat yield. In the case of Mr. Madsen's work the argument may be valid, but as I believe his butter-fat figures were calculated on the averages of percentages, this may explain a similarity in the milk and butter-fat figures. A truer indication may be obtained from the work of Robison and myself, to which Mr. Edwards has already made reference, where, despite what Mr. Edwards calls the phenotypic selection of the sires, the butter-fat correlation of granddaughters to their paternal grandsire is the same as to the maternal grandsire.

With regards to points (2) and (3), Mr. Edwards has shifted the grounds of his argument considerably. In one respect he remains consistent, in that he persists in confusing correlations based on genotype with those based on phenotype. Since he still misunderstands the original statements of Mr. Madsen, I feel that little good can result from a further debate upon these points.

As to point (4), I maintain that I was justified in challenging Mr. Edwards as to the accuracy of his calculation that the results obtained by Mr. Madsen might once in ten times be due to chance. I repeat that one in twenty expresses more accurately the possibility of Mr. Madsen's results being obtained by chance. Tables of the normal curve, which, as Dr. Wishart[2] admits, are for such large samples sufficiently accurate, show that a deviation of $-1 \cdot 64\sigma$ leaves only one-twentieth of the area to the left of that point. The fact that there is also a second twentieth to the *right* of the point $+1 \cdot 64\sigma$ is irrelevant, since positive deviations, however great, could not be cited in support of sex-linkage. The distinction is a simple one, though frequently overlooked. The point has been fully explained by Dr. R. A. Fisher.[3]

It is now four years since the facts first suggested to me the possibility that the hereditary transmission of milking capacity might be in part conditioned by sex-linked genes. Since that time, I and others have been pursuing this subject along various lines, and we have not yet been able to find a valid reason for jettisoning this hypothesis, which appears to be not only warranted by the results obtained by ourselves and others, but also explains many of the practical difficulties of breeders. Neither I nor my colleagues, however, are wedded to this hypothesis, but we still await criticism which might compel us to modify our views.

Polypharyngeal Planarians

AMONG a dozen specimens of the planarian, *Polycelis cornuta* Johnson, collected in August 1931 from a small pond at Liss in Hampshire, I observed one specimen with a well-developed double pharynx. I revisited this pond in March of this year and was able to collect several hundred specimens of the same planarian. In this pond *Polycelis cornuta* constituted more than 90 per cent of the planarian population, *Polycelis nigra* and *Dendrocœlum lacteum* being present in small numbers. On examining these specimens of *Polycelis cornuta*, one was again found with a double pharynx.

Polypharyngeal planarians have frequently been recorded from various districts on the Continent, but, so far as I am aware, this is the first time that this type of abnormality has been recorded from the British Isles. Previous records of polypharyngeal planarians have usually been from mountainous districts, but Thienemann[1] has recorded finding one specimen of a tripharyngeal *Polycelis cornuta* from among a hundred specimens collected from springs in Holstein. The dipharyngeal forms are evidently not common, but, from the fact that they have been found fairly easily in two collections made at different times, it may be assumed that this abnormality is established in the race living in this particular pond. *Polycelis cornuta* is a fairly common species in Britain and the existence of the double pharynx is quite obvious on examination, even with a simple lens, so that it is unlikely that these abnormal forms would have escaped notice.

The pond in which the dipharyngeal forms occurred is a small one, about five yards in diameter and less than one foot deep. It is on the slope of a hill and is supplied by a spring draining out of the soil. The temperature of the water of the pond in March 1932 was 6° C., and this temperature corresponded with that of the local streams. The temperature of deep springs from the chalk in the same district at the same time was 9·5° C. It can be assumed, therefore, that the water supply of this pond is not from a deep spring, which would maintain an even temperature of the water throughout the year. The temperature of the water in the pond at the time of my visit in March appears to show that it varies with that of the air, in the same way as other ponds and streams supplied by surface drainage.

Trochus niloticus, Linn. in Andaman Waters

DR. YONGE in "A Year on the Great Barrier Reef" (Putnam: 1930) states that certain animals like the horse-hoof clam spawn "at the peak of summer"; others like *Trochus niloticus* "during the entire winter".

My observations on the bionomics of *T. niloticus* on the east coast of the Andaman Sea reveal (1) that this species grows during the monsoon and 'winter' months, that is, July to March, and (2) that it starts spawning about the middle of the summer months, that is, April.

The temperature of the Andaman Sea has two definite rises and two falls in a year.[1] The first rise starts in February, to reach a climax in April-May, before the outbreak of the south-west monsoon; there is a fall during the monsoon. The second rise starts in July-August, to reach its highest point in October, before the north-east monsoon; and finally, the second fall begins in November. The first rise of temperature, that is, the April one, reaches a higher degree than the second, the October one. As remarked above, *T. niloticus* starts spawning in April, and it appears, therefore, that in the Andaman waters this mollusc has a minimum temperature above which alone it would spawn. This observation emphasises the idea that the marine invertebrates in tropical waters do not breed haphazardly but with a similar regularity to that observed in temperate waters.

Research Items

Yavapai Shamans.—In the course of a study of the south-eastern Yavapai of Central Arizona, otherwise known as the Mohave-Apache or Yuma-Apache (*Univ. Cal. Pub. Amer. Arch. Eth.*, vol. 29, No. 3), Mr. E. W. Gifford has recorded the methods and system of training of the shaman or medicine man of these people. Shamans' visions come in trances rather than in dreams, and his power is acquired while in a trance. A trance was usually the first intimation that a person was about to become a shaman. In it the god Amchitapuku talked to the novice, taught him songs, told him what to do and say, and how to help the sick. By the same means he revealed to the shaman whether a sick person would live or die. All treatment of the sick was at night. The shaman did not blow on the affected part, nor froth saliva; he sang over the patient and, while singing, saw a flash of lightning in the afflicted part. He then cut a cross there with a flake of glass and sucked the cut, finally producing from his mouth a worm-like object which he displayed to the patient as the cause of his illness. Four eagle feathers, a gourd, and a bull-roarer were employed in healing. Each of these feathers was stuck upright in a cardinal direction near the patient, and while the shaman was singing he touched the seat of the pain with one of them. Sometimes the bull-roarer was swung round as the shaman entered the patient's house. He thus communed with the goddess Widapokwi, and if she so advised him, he whirled it while singing. A sucking shaman was not blamed if a patient died, nor was he blamed for the death of other persons. If, however, a patient died, the shaman returned to the relatives all the property they might have given him.

Decorative Art in Oceania.—In a study of the decorative designs of Oceania based on material in the United States National Museum (*Proc. U.S. Nat. Mus.*, vol. 79, Art. 30), Mr. Herbert W. Krieger distinguishes six distinct geographical design-areas as showing differences in art forms and application of design. They are: Tonga-Samoa, New Zealand, Raratonga-Tubuai-Tahiti, Manihiki, the Marquesas, and the Hawaiian Islands. Tonga-Samoa is characterised by the use of straight lines, zigzags, and a derivative, the dentated line. There are some delineations of animals and men. In the New Zealand area curved lines with a pronounced tendency towards spirals show a clear reaction with Fijian and Papuan types of etched and painted designs. Stylistic art patterns are fixed and standardised. In the Manihiki area sculptures in wood are for the most part unknown; but small plaques with incrustations of shell arranged in symmetrical form are found. The Marquesan designs are more conventional. Two types of human face, strongly stylised, occur. In the Hawaiian area straight lines are decorated with nodes, zigzags, or angles; straight lines, parallel or crossed, form lozenge-shaped designs reinforced with dots or curved lines. In the Raratonga-Tahiti group we find designs derived from anthropomorphic models. All objects appear to have a religious significance. In an area so large as Polynesia and so heterogeneous there are few elements common to the whole area; but as one passes from west to east there is a developmental sequence in the plastic art.

Seasonal Colour-Changes in Mammals.—Apart from that major type of colour-change, from summer coat to winter white, which characterises certain mammals of arctic or subarctic origin, a well-known seasonal change in tint takes place in the common red squirrel, in which the gradual bleaching is attributed to light. Capt. Guy Dollman recalls Andersen's observations on the Indian rufous horseshoe-bat, where a progressive bleaching could not be due to sunlight, and parallels that case by a similar change in the African flying 'squirrel' or scaly-tail, *Anomalurus jacksoni* (*Proc. Linn. Soc. London*, 1931–32, pt. 3, p. 68). Three of four specimens from Uganda are redder than the type, and since light cannot be the cause of the bleaching in these nocturnal animals, it is suggested that the change may be due to oxidation of the dark pigment granules to a paler colour. Since, however, the formation of the dark colouring matter or melanin is said to be due to the action of molecular oxygen or of a specific oxidising agent in the cell, the subsequent reduction of melanin by the same agent seems unlikely, and we suggest hypothetically that the cause may be looked for in another agent to which even the nocturnal mammals are subject, namely, heat. The suggestion is based on the fact that experiment has shown that heat has a restraining effect on the deposition of pigment; although it may be that when the pigment is deposited, heat can no longer affect it. The possibility of the influence of heat on fixed pigment, however, is worth keeping in mind and testing.

Myxosporidia from Indian Fishes.—Dr. H. Ray, of the University of Calcutta, who is engaged in studying the myxosporidia occurring in fishes in Bengal, has sent NATURE a letter upon this subject, but lack of space prevents its publication in full. Of such sporozoa, only two species of *Myxobolus* and one of *Sphærospora* have previously been recorded from Indian fishes. Dr. Ray has found nine species of fish infected. The parasites belong to the genera *Ceratomyxa*, *Chloromyxum*, *Myxidium*, and *Myxobolus*. Several of the species observed are new to science, and accounts of these will be published at an early date. A species of *Ceratomyxa* was found to be fatal to *Gobioides rubicundus* under laboratory conditions; almost every organ of the body in these fishes became infected. Dr. Ray thinks that the possibility of rapid spread and serious effects of myxosporidian infections in the somewhat unnatural conditions of aquaria should not be lost sight of when investigation into occasional heavy mortality of the fish there is undertaken. He is at present studying this question.

Dominance and Modifying Factors in Cotton.—The crinkled dwarf mutation from Sea Island cotton, described by Dr. S. C. Harland, has recently been the subject of further investigation (*J. Genetics*, vol. 25, No. 3). He finds it to be a complete recessive in crosses with the type from which it arose, but that its recessiveness is incomplete in crosses with other members of the Peruvian group. When Upland cotton is crossed with crinkled dwarf, the F_1 is intermediate and the F_2 shows an unclassifiable series from normal to more extreme crinkled. The F_1 back-crossed repeatedly to Upland shows increasing dominance of normal, and in the F_2 from the first back-cross one family showed reversed dominance, 3 crinkled : 1 normal. These and other facts are discussed in the light of Fisher's theory of dominance, and it is concluded that while the genetic behaviour favours Fisher's theory, yet there are difficulties in accounting for the distribution of genes modifying dominance, since all the Peruvian types appear to be homozygous for such genes. The necessary assumption to account for this, namely, that the original normal population has been replaced by normals descended from heterozygotes, appears improbable.

In a further contribution, Dr. Harland gives an account of chlorophyll deficiency occurring in hybrids between Upland and Peruvian cotton and the Polynesian *Gossypium tomentosum.* Three independent pairs of factors are involved. The chlorophyll-deficient class was found to show a range from completely lethal to fully viable, which is interpreted as due to modifying factors. Mr. J. B. Hutchinson also contributes to this series of cotton studies by describing a semi-sterile type called 'crumpled' which originated in a cross between *G. Nanking* var. *soudanensis* and *G. arboreum* var. *sanguinea.* It is found to be due to two complementary factors the distribution of which differs from strain to strain in Asiatic cottons. One of these factors has been found in two strains of Sudan cotton and the other in 17 varieties belonging to five Asiatic species. A number of modifying factors has also been found here.

Bacterial Canker in Plum Trees.—A canker of plum trees which produces lesions on the stem, associated with rolled and yellowish leaves in spring which later die or wither, has been described by Mr. H. Wormald (*J. Pom. Hort. Sci.*, **9**, No. 4, pp. 239-256, Dec. 1931). Various fungi are found on the lesions during summer, and some of these have occasionally been reported as the actual causes of the malady. The author of the present work studied the appearance of symptoms throughout the year and found that the cankers in spring were full of cells containing bacteria. He isolated an organism which, upon re-inoculation in spring, produced typical cankers which later became the home of the fungi. The bacterium was the real cause; the fungi were quite secondary in their appearance. *Pseudomonas mors-prunorum* is the name suggested for the new organism. Methods of control are being tried, but no definite recommendations are given.

Solar Radiation at Tokyo.—Regular observations of the intensity of the solar radiation are being made at the Central Meteorological Observatory at Tokyo by means of a self-recording Moll-Gorczynski actinometer. The first seven quarterly actinometric bulletins giving hourly values of the radiation, beginning with the figures for Jan. 21, 1930, have been issued. The introduction, of which there is an English translation, describes the methods of observation. The radiation has to pass through a quartz plate 2 mm. thick before reaching the thermopile of the actinometer. Every day when the weather permits, the actinometer is calibrated with the aid of an Ångström compensating pyrheliometer. After the record has been reduced to the angstrom scale it is converted to the Smithsonian scale. The hourly values of radiation for each day in gram calories per sq. cm. per minute are set out in tables covering single months, and a weather diary for each day is given, the international weather symbols being employed to economise space. Various subsidiary tables have been added, which include figures for the mass of air traversed by the sun's rays and the coefficient of turbidity. This should prove to be a series of publications of importance to those workers studying problems connected with the heat-balance of the earth, for the frequent checks on the accuracy of the observations are likely to ensure a homogeneous and reliable record, of which there are all too few.

High Velocity Positive Ions.—Drs. J. D. Cockcroft and E. T. S. Walton have published a description of the high potential generator which has been used now with such spectacular results (*Proc. Roy. Soc.*, June). The method used consists essentially in the multiplication and rectification of the voltage of a transformer by an arrangement of valves and condensers, the insulation of the high tension system being distributed over a number of units. The rectifier system is of novel design, consisting of four glass cylinders placed end to end in the form of a tower twelve feet high, and containing suitable electrodes and hot filaments and exhausted continuously; with its four condensers, a potential of more than 700 kv. has been obtained, which is steady to within a few per cent. The method of making vacuum joints which has been used, although crude, seems to be efficient, when used in conjunction with pumps of high speed. It consists simply in putting two surfaces together, working a plastic substance round the joint with the fingers, and finally rubbing over the surface with tap-grease to seal small residual holes. For the earlier work, commercial plasticene was used with satisfactory results, but in the final apparatus this was replaced by a special low vapour pressure putty supplied by the Metropolitan-Vickers Electrical Co. The pumps used also worked with a low vapour pressure oil in place of mercury, thus making the use of liquid air traps unnecessary. The paper is illustrated by a photograph which shows the apparatus set up.

Polarisation of Electrons.—The fact that an electron can be described as having a magnetic moment and an axis of spin carries with it the implication that it should be possible to polarise a beam of electrons. Certain types of experiments are ruled out by the uncertainty principle, but it has been shown by Mott that it should be feasible to carry out the analogue of the old optical experiment of producing and detecting polarisation by successive reflection from two inclined mirrors, under rather stringent conditions. Mott's criteria have been fairly closely observed in experiments described by E. G. Dymond (*Proc. Roy. Soc.*, June). Rather fast electrons were used, and, to avoid multiple scattering, were projected on to two targets of thin gold foil. Many complications were encountered, and the experiment proved to be one of much difficulty, largely on account of the extreme feebleness of the twice scattered beam, but the conclusion is reached that a slight polarisation, of the order of one per cent, was present. Actually a polarisation of ten per cent was predicted by Mott's theory, so that an interesting discrepancy still persists. G. O. Langstroth (l.c.) has reported a negative result in an attempt to polarise electrons by successive reflection from two massive tungsten targets, which provides a problem less difficult than Dymond's experimentally, but considerably more complicated in interpretation.

Theory of Conical Loud Speakers.—Dr. N. W. McLachlan, in a paper read to the Physical Society on March 4, describes the symmetrical modes of vibration of truncated conical shells with special reference to loud speaker diaphragms. There are two salient types of vibration pertaining to these shells. First, radial modes as in a bell, and secondly, symmetrical modes as in a disc. The author discusses the latter type only, as it is this kind of vibration which is of importance in connexion with loud speakers of the hornless type. As the problem stands at present, it appears that to get a solution embodying the two radii, the apical angle, the thickness of the shell and Poisson's ratio for various edge conditions, a team attack by several investigators would be required. The present paper gives an account of a number of experiments carried out by the author. He used paper, glass, and aluminium shells. He found that the modes crowd together as compared with the segregation which occurs in the case of a disc. With thick glass or aluminium of comparatively low loss, the nodal frequencies are very clearly defined peaks. In the case of paper cones driven by coils of small mass, the peaks disappear

and the nodal region is indicated by a broad rounded contour. The influence of thickness, apical angle, and the mass of the driving coil are considered. Vibrations of the air column within the shell and the general requirements for loud speaker diaphragms are discussed. In a letter to NATURE (129, 202, Feb. 6, 1932) he reported the occurrence of resonances to the air column in the shell.

Television in Relation to Seeing.—"The Eye, as a Link in the Television Chain", formed the subject of a recent paper by Mr. W. D. Wright before the Television Society. Persistence of vision, an important factor in the cinema, is possibly even more influential in television. The critical frequency increases with intensity. The desired increase in the brightness of television pictures (at present somewhat faint) would therefore increase the numbers of scans per second necessary to avoid objectionable flicker. A light surround to the picture accentuates the sensitiveness of the eye to flicker and should be avoided. At present a speed of 20 pictures per second seems a fair compromise between the desirable and the feasible. 'Irregular scanning' helps in some measure to diminish flicker. The roving and mainly horizontal movements of the eye, and likewise its occasional blinking, tend to produce a rather troublesome stroboscopic effect. On the whole, the advantage in this respect seems to lie with pictures scanned horizontally. The present limitation in size of picture is admittedly a drawback. The author asks, "Is it really possible to obtain lasting enjoyment and entertainment from a picture which is, say, only three or four inches square?" The minuteness of the figures, coupled with the short focusing point for the eye, give rise to a sense of unreality. The brightness of the picture should be as high as possible; 5 candles per sq. ft. would be very satisfactory, 0·5 good, and 0·05 passable. Various factors that may occasion deficiency in contrast or distortion are mentioned. The conditions for a television picture in colour are considered too complex to justify detailed discussion.

Astronomical Topics

Comets.—Some doubt has been thrown on the existence of comet 1932 *h* (Schmitt) from the fact that Prof. Schorr at Bergedorf, Prof. G. Struve at Neubabelsberg, and Dr. W. H. Steavenson at Norwood have failed to find it; some positions that were thought to belong to it really belong to Newman's comet. The evidence for its existence is a photographic position by Schmitt on June 25, 99^{sec} east and 12′ north of Newman's, and a statement that Schmitt confirmed it on June 29. Continuation of the ephemeris of Newman for 0^h:

	R.A.	N. Decl.
July 16	15^h $0{\cdot}7^m$	21° 13′
20	14 57·4	22 36
24	14 54·9	23 51
28	14 53·2	24 58
Aug. 1	14 52·4	25 57

Dr. Bobone has computed the following elements of the comet 1932 *g*, discovered by Mr. Geddes in New Zealand; presumably they are based on observations made at Cordoba (Argentine) (*U.A.I. Circ.*, No. 390):

$$\begin{array}{ll} T & 1932 \text{ Oct. } 26{\cdot}95 \text{ U.T.} \\ \omega & \left.\begin{array}{l} 356^\circ\ 32' \\ 222\ \ 56 \\ 122\ \ 12 \end{array}\right\} 1932{\cdot}0 \\ \Omega & \\ i & \\ q & 1{\cdot}913 \end{array}$$

The axis of this orbit lies very near the ecliptic, suggesting possible periodicity, but there is no close resemblance to any previous comet. The comet will be well placed for southern observers for the next two months; it will then pass nearly behind the sun. It should be visible in Europe as a morning object about the end of the year. *Harvard Card* 224 gives the following position obtained at Cordoba:

June 27·0366 U.T., R.A. (1932·0) 10^h 55^m $16{\cdot}7^s$, S. Decl. 30° 53′ 25″, Mag. 9.

The Reinmuth Planet, 1932 *H.A.*—Dr. G. Stracke, of the Berlin Rechen-Institut, who was the first to deduce a good orbit of this remarkable planet, contributes an article on it to *Astr. Nach.* 5878; an accurately drawn diagram shows its orbit and that of the Delporte planet found in March, in relation to the orbits of Venus, the earth, and Mars. The only uncertainty now is the exact period; Stracke finds 1·8395 years, while Miss Covey and Dr. Wyse make it two months longer. Prof. H. E. Wood writes that he observed the planet from Johannesburg, though he has not yet sent positions; when they arrive, they will help in determining the distance from the earth and consequently the period; they will be about 2′ away from simultaneous northern positions in consequence of the proximity to the earth. Dr. Stracke brings out some singularities in the planet's motion; it was in opposition on April 24, and in conjunction with the sun only six weeks later. At discovery it was retrograding more than a degree per day, which instantly attracted attention; but if it had been discovered a week earlier its motion would have been less abnormal, and it might have passed as one of the usual host of minor planets, which did not seem to require close attention. On May 15 it was moving nearly 7° per day, a speed only exceeded by a few comets.

The latest observation now to hand was made by Prof. van Biesbroeck at Yerkes on May 15; it is possible that it may have been followed longer at Johannesburg. Attempts will be made to re-observe it as a morning object in August, but it will be a long way off and therefore faint.

Leyden Observatory.—An interesting feature of the report of the director of Leyden Observatory, Prof. W. de Sitter, is a description of the expedition of Dr. Hins and Mr. van Herk to an equatorial station in Kenya Colony to observe the azimuths of fundamental stars. The chosen station is 9000 feet high, and three-quarters of a mile south of the equator. It is well known that there are differences of declination in the standard catalogues of fundamental stars amounting to considerable fractions of a second; these arise from uncertainties in the correction for refraction. Several years ago Prof. de Sitter proposed the plan of making observations of the azimuths of stars from a station on the equator, thus getting rid of the correction for refraction. He sent Mr. Sanders with a small instrument to make trial observations at a station in the Portuguese Congo. The results were encouraging, and a more accurate instrument has been constructed by Messrs. Cooke, Troughton, and Simms, specially for the present expedition; it is reversible, and observations are made in both positions of the instrument. Stars near the equator appear to move vertically; those farther away have a slow motion in azimuth. An azimuth mark was erected 300 metres from the instrument, to check the zero point. Observations were begun on Nov. 30, and 148 complete observations were made by Dec. 31.

National Physical Laboratory, Teddington

Inspection by the General Board

ON Tuesday, June 28, the General Board of the National Physical Laboratory made its annual inspection of the Laboratory. A large number of visitors, including members of scientific and technical institutions, government departments, and industrial organisations, were present, and were received by Sir Frederick Gowland Hopkins, president of the Royal Society, chairman of the Board, Sir Richard Glazebrook, chairman of the Executive Committee, and the director, Sir Joseph Petavel.

In the Duplex Wind Tunnel of the Aerodynamics Department, tests were in progress on a model of a large four-engined monoplane, complete with airscrews, to determine the rolling and yawing moments at various angles of yaw and at various angles of the controls. The aim of the tests is to explore the efficiency and general characteristics of the control surfaces with and without the airscrews in operation, and to investigate the efficiency of the overall design. For this type of work a number of small gear-boxes of special design have been constructed, so that as many as six separate airscrews can be operated at once from a single electric motor situated in the fuselage of a model.

Apparatus for tests on the thrust and torque of model high-pitch airscrews was also on view. In consequence of the high speeds now required of aircraft, there has been a demand for airscrews of this type. The tests are expected to provide data both for these designs and for comparison with theory. An interesting feature of the apparatus is the three-phase motor constructed in the Laboratory for driving the screw shaft. Though of dimensions so small that it produces no appreciable interference with the airstream when mounted behind an airscrew of three feet diameter, the motor is capable of delivering 12 brake horse power for extended periods.

For purposes of demonstration, the aerodynamic balance for use in the Compressed Air Tunnel, together with the accessory electrical indicating apparatus, was exhibited. The balance consists essentially of a braced ring frame, in the centre of which the model is rigidly held. The frame can oscillate about three parallel axes, the change from one axis to another being effected electrically from outside the tunnel. From measurements of the moments about the three axes, one of which passes through the centre of gravity of the model, the lift and drag can be computed. A single set of electromagnetic coils, arranged on the principle of the Kelvin current balance and mounted at the top of the frame, suffices to measure the couple about each axis. The stability and sensitivity of the balance can be varied by electromagnets situated at the bottom of the ring frame. The whole of the electrical apparatus can be controlled from outside the tunnel.

An improved means of visualising airflow was demonstrated in the department. The method adopted is a modification of the one shown last year, when airflow was rendered visible by the shadow bands produced when air heated by thin wires was suitably illuminated. In the present method, the wires are replaced by a spark gap in which high frequency sparks are produced. The shadows in this case take the form of a series of semi-opaque 'dots'. By stroboscopic methods it is possible to isolate any given 'dot', the motion of which can then be observed visually or from photographic records. The method is being used in an attempt to determine the nature of turbulent flow in air.

The Engineering Department has given considerable assistance to the British Standards Institution in the design, standardisation, and testing of lifting gear components. Specimen links and hooks, etc., before and after test, were exhibited. On behalf of the Home Office, the department has undertaken investigations into the effect of service on the pitch of calibrated chains, and the effect of heat treatment on threaded parts of cranes and shackles. Special machines designed and constructed in the department for this work were demonstrated. In the chain tests, the chain is driven under conditions closely approximating to those obtaining in block and tackle. The effect of periodic heat treatment is being studied. In the case of threaded shackles and swivels, the machine applies repeated lifts to the specimens under test, the degree of impact being made to resemble closely conditions existing in a 30 cwt. crane.

In connexion with an investigation for the Lubrication Research Committee, experiments were in progress on journal bearings to determine the variation of the coefficient of friction with oil viscosity, load, speed, and clearance, and the effects of speed and clearance on the seizing temperature. These problems have a special application to motor and aircraft engines, and special machines have been constructed for the work. The experiments tend to show that lighter oils than usual may be used with safety. It is found that an increase in the clearance from two or four thousandths of an inch to sixteen thousandths leads to an appreciable decrease in the seizing temperature.

An investigation has been commenced of the way in which stress varies with strain during impact tests of materials. A machine of the swinging hammer type is employed, and the well-known piezo-electric properties of quartz crystals are utilised to record the changes of stress during impact by means of a cathode ray oscillograph. The time scale on the record is obtained by utilising the change in voltage when a condenser is discharged through a resistance. A method of measuring the strain electrically is being developed.

Of interest also were 'cupping' tests on sheet metal. Information is needed regarding the properties of sheet metal used for cold pressing operations. Various cupping tests were shown, and in particular one in which the metal is deformed by oil pressure until fracture occurs. The method can be used to give a fair indication of the tensile strength of the material. The apparatus is fitted with an autographic method of recording load and distension.

In the Metallurgy Department, research is in progress on the constitution of certain magnesium alloys with the view of obtaining better mechanical properties after heat treatment. In connexion with this work, a method has been employed of purifying magnesium by sublimation. Ordinary magnesium is heated *in vacuo* in a crucible to a temperature about 50° C. below its melting point, when it sublimes and is deposited on the cooler parts of the furnace tube, to which it is prevented from adhering by a layer of magnesium oxide. The tubular deposit is afterwards withdrawn. Most of the impurities are left behind in the crucible.

For research on the cracking of boiler plates, an apparatus has been constructed for studying the effects of corroding media, such as caustic soda, on the stability of stressed steel at boiler temperatures and

pressures. Small specimens of boiler plate completely immersed in a corrosive solution can be tested under tension in a seamless high pressure cylinder of steel, which is heated electrically. Steam pressures up to 500 lb. per square inch can be obtained. Apparatus has also been developed for studying the corroding action of superheated steam on materials which are suitable in other respects for use in steam power plant. A special boiler is utilised, consisting essentially of a long coiled tube of rust-resisting steel, which is heated electrically and through which water is circulated. The steam generated is superheated electrically in a stainless steel vessel which contains the material under test. Steam pressure of 1000 lb. per square inch at a temperature of 600° C. can be obtained with the apparatus.

Research work is being carried out in the department, under the auspices of the Dental Investigation Committee of the Department of Scientific and Industrial Research, to determine the factors which affect dimensional changes in dental fillings when these are packed into a tooth. The effects of pressure during the operation of filling, of particle size in the amalgam, and of the proportion of the constituents in the amalgam are being investigated. For this work special lever dilatometers have been designed. These are enclosed in a specially constructed thermostat, so that the experiments can be conducted at ordinary mouth temperatures.

In a number of researches in the department, crucibles and tubes impervious to gases are needed. These are unobtainable commercially in Great Britain and their manufacture has been investigated in the department. Specimens of non-porous sheaths of pure alumina glazed by fusion were exhibited, and their use in optical pyrometry, where the presence of gases and vapours would affect the measurements, was demonstrated.

In the Metrology Department a new balance to weigh loads up to one kilogram has been constructed. This balance will be used for work of the highest precision and in particular for the periodic verification of the national standards of mass. Provision has been made for weighing either in air or *in vacuo*, and for accurate adjustment of the knife edges. To obviate magnetic disturbances, no magnetic material has been employed in the construction of the balance. The apparatus will be operated under steady temperature conditions, and provision has been made for reading the balance and for interchanging weights by means of remote controls.

Experimental apparatus for the measurement of very fine wire such as is used in electric lamps has been developed in the department. The instrument is a combination of a mechanical and optical lever, giving an overall magnification of 15,000. The diameter of the wire can be measured to a few millionths of an inch, and very small variations in thickness can be detected.

In the Heat Division of the Physics Department a number of investigations were in progress on behalf of the Food Investigation Board. Apparatus has been constructed for the measurement of the thermal conductivity of heat insulating materials at low temperatures. The equipment, which is fitted with a novel guard ring system, includes a refrigerating plant and automatic control for maintaining the cold plate at any desired temperature. Considerable work has also been carried out in connexion with the heat transfer between air and banks of metal pipes through which a refrigerant is circulated. The laws of heat transfer for various assemblages of pipes and for a succession of lengths of pipes placed longitudinally in an air stream have been investigated.

For measurements of the thermal conductivity of heat insulating materials at high temperatures, apparatus has been constructed in which samples, the surfaces of which are not flat, can be tested. A Silit heater furnace is so arranged that the face of the specimen can be viewed with an optical pyrometer. Of interest also was a calorimeter for the measurement of the heats of combustion of gases. An adiabatic system is adopted in which the calorimeter is heated electrically at a controlled rate. The apparatus is capable of giving results to a high order of accuracy.

In the Radiology Division considerable work has been done in connexion with the realisation of the X-ray unit of quantity, the Röntgen. In this work precise control of the X-ray output is required, and a constant potential generator has been constructed which enables voltages of 40-230 kilovolts to be applied with a voltage variation not exceeding 1 per cent. A new primary ionisation chamber has also been designed. It is of interest to note that in an intercomparison of the new unit by the three national laboratories of America, Germany, and Great Britain, agreement was obtained within 0·5 per cent.

As an example of the way in which X-rays can be applied to industrial problems, mention may be made of the X-ray examination of chromium plating, which can vary from a bright hard deposit to a grey matt one, depending on the conditions in the plating bath. It is found that the differences in the deposit are due to variations in the shape and size of individual crystals. The brilliant surface is almost invariably associated with the smallest grain size.

In the Optics Division, charts were shown illustrating the new system of colorimetric standardisation adopted by the International Commission on Illumination in 1931. The trichromatic system of colorimetry developed at the Laboratory, in which three spectrum colours are employed as primaries, is utilised. A standardised illuminant is used consisting of a tungsten gas-filled lamp and a special colour filter. The standard colorimetric apparatus used at the laboratory was exhibited.

In the Sound Division the considerable demand for acoustical tests of absorbent materials used in the correction of defective auditoriums is reflected in various improvements in apparatus employed for the work. The measurement of sound intensity in absolute units has received considerable attention, particularly with the view of the absolute calibration of high quality electrical microphones, such as are required for modern developments in gramophone recording and in broadcasting.

In connexion with the rapid visual observation or photographic recording of the variation with frequency of the sound intensity of the note emitted by a loud-speaker, a novel use is made of a cathode ray tube. By means of a special circuit, the intensity of sound from the loud-speaker is plotted visually against a frequency scale instead of the time scale which is usual in oscillographic work.

In the Electric Standards Division of the Electricity Department was shown a piezo-electric quartz oscillator in the form of a ring, to serve as a primary standard of radio frequency. Experiments have shown that the modulus of elasticity of a quartz ring cut with its plane perpendicular to the optic axis is practically constant for all directions in this plane. This form of oscillator is thus eminently suitable for use as a standard of frequency. The oscillator is supported in a vacuum chamber and is thermostatically controlled.

In connexion with measurements of permeability, demonstrations were given of the changes which may occur with time in some materials when a small alternating magnetisation is superimposed on a large d.c. magnetisation. It has been found that in such cases the value of the permeability decreases continuously

for some time after the current is switched on. The amount of change varies with the material and the amplitude of the alternating magnetisation.

In the Electrotechnics Division, apparatus was shown for analysing the motion of rapidly moving automatic switchgear. An oscillographic method is employed, and from the records it is possible to determine the velocity of the moving parts while the switch is being broken, and also the time taken to complete the breaking of the circuit.

In the Wireless Division the fundamental work on very short waves has been continued. For comparison with theory, an apparatus has been developed for the study of the propagation, along the earth's surface, of ultra-short waves of wave-length 1·6 metres. Measurements are made of the decrease of signal strength with distance, at a height up to about 5 metres. A small, single valve, retroaction type oscillator is used as the transmitter, and no aerial is employed. The intensity measurements are made from a distance, with the aid of a telescope, to avoid disturbances in the field due to the proximity of the observer.

Another interesting exhibit showed the production and measurement of oscillations of wave-lengths between 14 and 80 centimetres. These waves are produced by the oscillation of electrons about the grid, which occurs in some valves when the grid has a high positive and the anode a slightly negative potential with respect to the filament.

In connexion with the investigation of the effects of glare undertaken by the Photometry Division, a new form of photometric pupilometer has been devised. In this instrument the observer views an ordinary photometric field, both halves of which are illuminated by the Maxwellian method, in which the light source is focused at the observer's eye. The illuminant for one half of the field is a bright spot, the image of which is considerably less than the smallest diameter of the pupil of the eye. The other half of the field is illuminated by an extended surface, so that the amount of light received varies with the aperture of the pupil. By making a photometric balance it is possible to determine the size of the pupil.

In the High Voltage Division, two high voltage sources of direct current have been constructed, incorporating in one case full-wave and in the other half-wave rectification. The former, which is capable of giving 200 kilovolts, will be used for providing the accelerating voltage for an impulse generator and for general research. The latter, designed for 100 kilovolts, is primarily for use with a high voltage cathode ray oscillograph.

In the William Froude Laboratory, tests were being conducted with a model high speed steamer to determine the effects of rough water on the resistance of ship forms and upon the propeller efficiency, with the view of obtaining improved ship economy at sea. The model was entirely self-propelled through rough water created by the wave machine. Measurements were made of the speed, the power required to drive the model, and the thrust of the propellers. At the same time continuous records were made of the pitching of the hull. Of interest also was a model of an improved design of Thames barge constructed to the designs of the Laboratory. Comparative tests with barges of normal type have shown that with the new design a 33 per cent improvement in speed is obtained, while the power expenditure of the tug is slightly reduced.

International Congress of Prehistoric and Protohistoric Sciences

NOW that the programme is virtually complete, it is safe to predict success for the first International Congress of Prehistoric and Protohistoric Sciences, the first international archæological congress to meet in Great Britain since 1868. When the members assemble in London on Aug. 1, practically every nationality will be represented, and the communications to be submitted will afford a very fair conspectus of the more important departments of prehistoric research as it stands to-day. British archæological studies in various parts of the world, in particular, will be well represented.

Some preliminary information relating to the organisation of the Congress and the excursions of archæological interest which are to follow has already been given in NATURE (see March 26, p. 479) and need not be repeated. In addition to the communications which will be presented to the sections of the Congress at King's College and the presidential address, in which Sir Charles Peers will review the beginnings of archæological studies in Great Britain, discourses will be delivered at general meetings to be held in the evening on Tuesday, Wednesday, and Friday in the Congress week. The speakers will be: Dr. Cyril Fox, director of the National Museum of Wales, on the control of physical geography in the early history of human habitation; and Mr. E. T. Leeds, keeper of the Ashmolean Museum, Oxford, and Mr. T. D. Kendrick, of the British Museum, on the outstanding material expressions of the Celtic and Teutonic civilisations. A fourth general meeting on Saturday morning will be addressed by Mr. O. G. S. Crawford on "Air Photography and Archæology". Here may also be mentioned, as outside the sectional routine, though connected with the proceedings, a visit to the famous palæolithic gravel pit at Swanscombe and an extensive exhibition at Bedford College illustrative of the report which Miss Caton-Thompson will read on her investigation of the prehistory of the Kharga Oasis, Egypt.

Turning to the work of the sections, it is possible to mention here a very small selection only of the large number of papers which have been accepted and allocated to the programmes of the five sections into which the work of the Congress has been classified. In Section I. (Human Palæontology), under the presidency of Sir Arthur Smith Woodward, the most attractive topic undoubtedly will be the recently discovered human remains from Mount Carmel, Palestine. Of neanderthaloid type, but aberrant from that type, they will be described, perhaps exhibited, by Mr. T. McCown, the finder, and discussed by Sir Arthur Keith. The morphology and antiquity of man in America will be the subject of discussion by Dr. Bruno Oetteking, and Dr. L. S. B. Leakey will describe the fossil teeth of Miocene anthropoids recently found by him on the shore of Lake Victoria in East Africa and the circumstances of their discovery.

Mr. Reginald Smith, presiding over Section II., will be concerned with a variety of problems relating to the old stone age, ranging from Africa to the extremes of Europe and Asia. Dr. L. S. B. Leakey will deal with the prehistoric cultural sequences at Oldoway, Tanganyika, and Messrs. Miles Burkitt and E. J. Wayland will discuss the Mgosian culture of Uganda. Prof. R. Vaufrey's paper on the Acheulean of Gafsa, should be valuable. The Abbé Breuil will give the results of his first-hand observation on fire and the bone and stone implements in the cave of Peking man, and he will also review our present knowledge of palæolithic

cave art. A department of the latter topic, the art of the Spanish caves, will be the subject of consideration by M. L. Pericot. Dr. B. S. Petri will describe the palæolithic culture of Siberia.

A number of members will deal with aspects of mesolithic culture: M. Reygasse on the Tardenoisian of North Africa, Prof. Antoniewicz on early man in north-east Poland and Lithuania, Prof. E. Plopson on Rumania, and Prof. R. Serpa da Pinto on Portugal.

Questions relating to the neolithic, bronze, and iron ages in the ancient world fall to the province of Section III., which being by far the largest section, has had to be subdivided. Cis-Alpine European prehistory, under Prof. H. J. Fleure, will devote considerable attention to megalithic monuments, with papers by Prof. Daryll Forde on the varied typology of Breton megaliths, the veteran M. Le Rouzic on the relative chronology of the prehistoric burials of the Morbihan, Prof. R. A. S. Macalister on the horned cairns of Ireland, Mrs. Cunnington on 'Wooden Circles', and Mr. H. St. George Gray on his excavation of Avebury. The interest of this group is rivalled by Prof. Siret on the problem of the æneolithic age and M. Vouga on his investigations in the lake villages of Switzerland. Mr. C. A. R. Radford will describe the hill-villages of the south-west of England, Mr. Hencken will discuss the Cornish tin trade, and Mr. A. Keiller will give an account of the extremely important settlement which he has excavated at Windmill Hill. A question which has long demanded ventilation will be opened by Mr. Brynner Jones on the origin of British domestic cattle and especially the domestic ox.

In the section dealing with the Near East, under the joint presidency of Prof. J. L. Myers and Mr. Sidney Smith, importance will be attached to Sir Arthur Evans's demonstration of the great cleavage between Knossos and Mycenæ in Late Minoan i.b. and the later unifying reaction from Crete. Mesopotamia is represented by, among others, Mr. Leonard Woolley on the early graves of Ur, Mr. Harden on painted pottery from Kish, and Dr. H. Frankfort on Syrian and Anatolian influences in Mesopotamia; while from Anatolia, Dr. H. van den Osten will describe the æneolithic settlement at Alishar in Cappadocia. There may also be mentioned Prof. Gordon Childe on the bearing of a newly discovered metal type from the east on European bronze age chronology, and Dr. O. Menghin on excavations at Beni Salameh in relation to their significance for European prehistory. This must suffice, though it is far from exhausting the list.

The section devoted to areas outside Europe will be much preoccupied with the archæology of beads, especially from Indian iron age burials in the Deccan, described by Mr. E. H. Hunt, and from China, the latter being designated as "of foreign origin". Prof. C. G. Seligman and Mr. Beck jointly will be responsible for the discussion of the latter, and Mr. Beck for the former.

The transition from prehistory to history, the work of Section V. under Mr. E. T. Leeds, deals with the movements of races, Saxons, Vikings, Slavs, etc., in the early centuries of our era. Dr. Schetelig, the foremost of Viking archæologists, will cover broadly the excursions of this people, and Prof. T. Balodis will discuss Lettish origins in this period. Tombs of the Roman iron age in North Jutland will be described by Prof. J. Brønsted, and Dr. A. W. Brøgger will review recent evidence bearing on the iron age in Norway. Mr. E. MacNeil will deal with the Picts, Mr. C. Hawkes with the relations of iron age enclosures in Britain and on the Continent, and last, but by no means least in interest, Mr. E. T. Leeds will review the evidence for the penetration of the Saxons into the upper Thames region.

University and Educational Intelligence

EDINBURGH.—Curricula for the degree of B.Sc. with honours in anthropology have been approved.

Following on the resignation of Dr. C. B. Williams of the lectureship in agricultural and forest entomology, the two lectureships in entomology in the University have been more closely correlated. Dr. A. E. Cameron, at present lecturer in medical entomology, has been placed in general charge of the instruction in entomology in the University, and Mr. J. W. McHardy, formerly entomologist attached to the Medical Department of Tanganyika Territory, has been appointed as the other lecturer in entomology.

Prof. A. J. D. Porteous, McGill University, has been appointed to the lectureship in ancient philosophy about to be vacated by the resignation of Mr. R. P. Hardie.

Intimation has been received of the following resignations: Dr. T. W. M. Cameron, lecturer in helminthology, on appointment as research professor in helminthology at McGill University; Mr. A. D. Hobson, lecturer in zoology, on appointment to the chair of zoology at Armstrong College, Newcastle; Dr. Edward L. Ince, lecturer in mathematics, on appointment to the Imperial College of Science, South Kensington, London.

LONDON.—University post-graduate travelling studentships of the value of £275 for one year have been awarded to Dr. B. W. Bradford (Imperial College of Science and Technology) and Muriel H. E. Long (King's College and King's College Hospital). Dr. Bradford proposes to study the adsorption of gases on metals with particular reference to polar factors, at Frankfort-on-Main, and Miss Long will study surgery and its practice in Vienna, Cologne, Berlin, and Budapest, making Vienna her base, and specialising in stomach surgery.

PROF. A. C. MENZIES, professor of physics at University College, Leicester, has been appointed professor of physics at University College, Southampton.

ECONOMIC depression and unemployment in America have stimulated interest and activity in what is known as the 'educational guidance' movement. An official report on recent developments of the movement is published in *School Life* for May, which also contains an editorial describing how continuation and other schools in various parts of the country are adapting their resources to the task of aiding the unemployed. Among the evidences of increased attention to educational guidance is an increase in the number of schools providing organised guidance services. In Pennsylvania alone 800 now have counsellors or advisers on an extra-curricular, part-time or full-time basis, or have established group guidance through classes in opportunities or occupations. Many State and local communities are organising associations for promoting public-school guidance programmes. Guidance figures more largely in programmes of educational conferences, local, State, and national. The output of literature bearing on the subject is enormous, including textbooks for teachers' training colleges, occupational studies issued by directors of education, reports issued by associations, such as the American Vocational Association, vocational surveys and monographs by research workers. Educational broadcasting programmes also give prominence to vocational guidance, while State departments are including guidance work in State courses of study. In Idaho, the State Board of Education has arranged for the formulation of a State guidance programme.

Calendar of Geographical Exploration

July 18, 1801.—Matthew Flinders' Journeys

Matthew Flinders sailed from Spithead in the *Investigator*, commissioned to explore the coasts of Australia, especially the little-known south coast. He discovered Spencer Gulf, St. Vincent Gulf, and Kangaroo Island, and, in a later voyage, circumnavigated Australia. His scientific work was of a high order and added much to our knowledge of magnetism, meteorology, and hydrography. He is said to have been the first to discover, and make corrections for, the effect of iron in the ship on the magnetic compass. In 1798, Flinders and Bass had sailed through the strait between Australia and Tasmania. Flinders achieved success in spite of many difficulties, which included leaking vessels, scurvy, and on one occasion the wreck of his vessel on a coral reef. Undaunted, he set off in a rowing boat to secure help, while the officers and men camped on a sandbank.

July 19, 1619.—Dutch Exploration of the West Coast of Australia

Two ships of the fleet commanded by Frederik Houtman touched the west coast of Australia in 32° 20′ S. Steering northwards to 27°, the commanders came to the conclusion that the coast formed part of the mainland off which Dirk Hartogszoon had, in October 1616, discovered Dirk Hartog Island. The knowledge of the west coast of Australia gained by several Dutch voyages at this period, including that of the *Leeuwin* in 1622, from which the southern cape was named, resulted from an order of the directors of the Dutch East India Company. They instructed captains sailing east from the Cape of Good Hope to take a more southerly course, in the hope of finding a better route to Java; thus within thirteen years, 1616–1629, the west coast of Australia between Cape Leeuwin and 21° S. was charted.

July 19, 1738.—Bouvet Island

Lozier Bouvet sailed from Lorient with two ships fitted out by the French East India Company. Stories of a pleasant land lying south of the Cape of Good Hope, led to the dream of establishing upon it a port of call for French vessels trading to India and China. The stories date back to the early sixteenth century, when a Norman noble, the Sieur de Gonneville, on a voyage to India, was driven ashore on a land still unidentified, but possibly southern Brazil. On Jan. 1, 1739, Bouvet sighted land, now known as Bouvet Island. Bouvet's voyage disposed of the more fantastic theories about Gonneville Land: he sailed for 48° of longitude roughly in 55° S. He described for the first time the huge flat-topped antarctic icebergs.

July 20, 1793.—Alexander Mackenzie in North America

Alexander Mackenzie reached the Pacific at the mouth of the Bellacoola River. He left England in 1792, proceeded to Chipewyan, and later wintered on the Peace River. On June 12 he reached the sources of the Parsnip, and by a short portage arrived at the Fraser system. He then crossed to the Bellacoola and followed it to its mouth, thus showing the practicability of intercourse between the Atlantic and Pacific Oceans. In 1789 he sailed down the Slave River to the Great Slave Lake and followed it to its delta, where, from Whale Island, he saw the Arctic Ocean. This journey was a remarkable feat, 2990 miles of difficult country having been covered in 102 days. These two achievements place Mackenzie in the front ranks of exploration.

Societies and Academies

LONDON

Geological Society, May 25.—Baron Ferencz von Nopcsa: The influence of geological and climatological factors on the distribution of non-marine fossil reptiles and Stegocephalia. A study of the terrestrial tetrapods and their distribution indicates three lines of migration in Upper Palæozoic and Lower Mesozoic times: (1) North America to Europe, thence through India and the Malay Archipelago to Australia, and from there to South America; (2) Central Asia to South Africa; and (3) Africa to South America. In Jurassic, Cretaceous, and Tertiary times there appear four lines: (1) Europe to Asia, the Malay Archipelago, and South America; (2) Asia, Fenno-Scandia, Greenland, and North America; (3) Central Asia to South Africa; and (4) North Africa to Brazil. To some extent these migratory lines are the same as those of Upper Palæozoic and Lower Mesozoic times. An attempt is made to correlate them with large-scale tectonic movements of folding and marine transgression, together with continuous changes in the ecliptic, bringing about a cycle of climatic and seasonal changes.—**K. A. Davies**: The geology of the country between Abergwesyn (Breconshire) and Llansawel (Carmarthenshire). The country described lies on the north-western side of the Towy anticlinorium. The rocks belong wholly to the graptolitic facies, and are very similar to those in adjacent areas which have already been described. It is suggested that the differences in grain are indicative of the varying depth of the sea-floor when deposition took place, the coarse deposits being laid down in banks tailing off from the areas made shallow by the cross-folding movements.—**K. A. Davies and J. I. Platt**: The conglomerates and grits of the Bala and Valentian rocks of the district between Rhayader (Radnorshire) and Llansawel (Carmarthenshire). A description is given of the distribution and field characteristics of the arenaceous bands, as well as a petrographical description of the included pebbles of the conglomerates and of the heavy mineral constituents of the grits. Most of the pebbles are quartzite and vein-quartz; sandstones, shales, etc., also occur frequently, but numerous pebbles of igneous rocks were found, as well as a few metamorphic types. The majority of the igneous pebbles are acid volcanic rocks, but interesting intrusive types also occur. All the igneous rocks are rich in soda.

Royal Meteorological Society, June 15.—G. I. Taylor: The resonance theory of semidiurnal atmospheric oscillations. The theory that the semidiurnal oscillations in the atmosphere are due chiefly to resonance requires that a free period very close to 12 hours shall exist. Theory shows that the corresponding speed of a tidal free wave is 910 ft. per sec., but direct calculation, and also observations of the Krakatoa air wave, agree in giving the velocity of free gravity waves as about 1050 ft. per sec. It has been suggested that this discrepancy might be explained if rapid pressure changes take place adiabatically while semidiurnal changes are more nearly isothermal. This theory is untenable, because the radiation or conduction necessary to produce any appreciable difference in the speed of the wave from that appropriate to adiabatic changes would give rise to so much damping that amplification by resonance to the desired extent would be impossible, even if the free period of the atmosphere were exactly 12 hours.—**H. L. Wright**: The variation of soil temperature below turf: a discussion of observations at Kew Observatory. Heat passes from 10 cm. to 20 cm. more rapidly

by about one hour and a half than is consistent with the decrease in the ranges of temperature at these depths. The suggestion is advanced that the grass interferes with the normal course of heat conduction. —**J. M. Sil**: Variations in potential gradient caused by some meteorological phenomena. The author has brought together a number of examples of abnormalities in potential gradient and has endeavoured to trace the connexion between them and some meteorological phenomena such as strong insolation, strong wind, the occurrence of a sea breeze, dust storm, etc. The abnormal effect caused by a dust storm was also produced experimentally on a calm day by blowing a small quantity of local dust particles at a point 3 ft. below the collector, when the earth's positive field was quickly reversed.

PARIS

Academy of Sciences (vol. 194, pp. 1869–1992, May 30).—The president announced the death of Roland Thaxter, *correspondant* for the Section of Botany, and of Albert Durand de Grossouvre, *correspondant* for the Section of Mineralogy.—**Ch. Lallemand**: Some geographical discoveries made recently in the antarctic region. Results obtained by the whaler *Norvegia*, a vessel specially equipped for survey work.—**L. Blaringhem**: Intersexual individuals in *Aquilegia*.—**P. Viala** and **P. Marsais**: A parasite of vine mildew. *Trichothecium plasmoparæ* has been found to be a parasite of the mildew fungus of the vine. The possibility of utilising it to fight the mildew is discussed.—**Charles Achard, Augustin Boutaric,** and **Maurice Doladilhe**: The influence of heating serum on the flocculation caused by dilution with distilled water. After heating to temperatures between 48° and 60° C., dilution with distilled water gives no separation of globulins.—**Maurice Gignoux**: The possibility of the existence of the Neocomian in the Embrunais zone on the right bank of the Durance.—**Georges Bouligand**: Level ensembles of a function of the distances of a point with several ensembles.—**S. Mandelbrojt**: The Dirichlet series the exponents of which are linearly independent. —**Vladimir Bernstein**: A generalisation of the exponential summation method of Borel.—**Mlle. Mary L. Cartwright**: The Borel directions of integral functions of finite order.—**J. Leray**: The movements of unlimited liquids.—**Max Serruys**: The calculation of an upper limit of the duration of detonation in internal combustion motors and the explanation of the presence of a gap in the diagrams given by certain electric manographs.—**Georges Mabboux**: The photo-elasticimeter extended to the study of reinforced concrete. An application of optical methods capable of showing changes in structures which have been built some time.—**J. Dufay**: Emission bands and lines in the spectrum of the night sky.—**R. Wavre** and **P. Dive**: An example of a multiform harmonic function furnished by the theory of Newtonian potential.—**Jean Jaffray** and **Pierre Vernotte**: The existence of high frequency oscillations in the secondary current of high tension magnetos.—**Michel Durepaire**: A method of comparison of small capacities.—**G. A. Beauvais**: A radiometer sensible to Hertzian waves.—**Antonio Rostagni**: The properties of gases ionised with high frequency currents.—**Jean Louis Destouches**: The theory of the diffusion of neutrons, absorption coefficient, and ionisation.—**M. E. Nahmias**: Anomalous absorption by lead of X-rays at about 210 kv. This anomalous absorption, of which no explanation is obvious, agrees with earlier figures given by Jaeger. —**I. I. Agarbiceanu**: The fluorescence spectrum of I_2.—**D. Skobelzyn**: The Compton effect of the very hard γ-rays of ThC''.—**M. Haïssinsky**: The electrolytic deposit of polonium on various metals.—**S. Rosenblum** and **G. Dupouy**: Absolute measurements of the velocities of the principal groups of α-rays. Work done using the large electromagnet of the Academy of Sciences. The velocity of the α-rays of RaC′ ($1{\cdot}922 \times 10^9$ cm./sec.), used as a base number, agrees with the figure given by Rutherford and Robinson.—**Jean Jacques Trillat**: The changes of structure of nitrocellulose films in the course of drying.—**Ch. Zinzadzé**: The buffer power of some slightly soluble phosphates. A diagram is given showing the buffer action of magnesium and calcium phosphates.—**H. Muraour** and **G. Aunis**: The influence of the temperature of the (explosive) powder on the variation of $\int p.dt$ at different densities of charge.—**Victor Lombard** and **Charles Eichner**: The diffusion of hydrogen through palladium. Curves are given showing the amounts of hydrogen diffused through palladium at constant pressure with temperatures varying between 196° and 600° C., and at constant temperature (372° C.) with varying pressures.—**Mlle. Suzanne Veil**: The precipitation of methylene blue by various electrolytes in gelatine.—**Maurice Doladilhe**: The influence exerted by an electrolyte on the fixation of colloidal colouring matters by the granules of a hydrosol.—**M. Auméras** and **A. Tamisier**: The decomposition with increasing temperature of the ammine and hydrated metallic complex compounds.—**T. Karantassis** and **L. Capatos**: The use of potassium stannichloride ($K_2SnCl_4 . 2H_2O$) in analysis. This salt is stable and non-hygroscopic and can be used in volumetric analysis.—**A. Sanfourche** and **Jean Henry**: The action of water on dicalcium phosphate.—**P. Cristol** and **J. Cayla**: A new conjugated molybdenum blue, boro-molybdic blue. —**Albert Kirrmann**: The condensation of pyruvic acid with aldehydes.—**Lespieau** and **Wiemann**: The synthesis of racemic mannite. Acrolein is oxidised with silver chlorate in the presence of osmic acid: one of the products is shown to be mannite.—**Mailhe, Marty,** and **Gaudry**: The decomposition of hydroaromatic hydrocarbons. A study of the decomposition of cyclohexane at temperatures between 500° and 750° C. in presence of silica gel as catalyst.—**Ch. Courtot** and **H. Hartman**: The chromatability of the azo colouring matters produced from the hydroxyquinolines.—**Georges Lévy**: The preparation of a new ethylnaphthol.—**V. Cerchez** and **Mlle. C. Colesiu**: The reduction of the acetyloximino esters.—**J. Orcel**: The existence of coronadite in the manganese minerals of Bou Tazoult, Imini region, Morocco.—**Raymond Furon**: The phosphate rocks of the Gabon coast.—**E. Chaput**: Geological observations in Asia Minor: the upper Cretaceous in Central Anatolia.—**Elie Gagnebin**: The presence of the Gault in the breccia of Chablais (Haute-Savoie).—**Louis Dubertret**: The structural evolution of the Levant States under the French mandate.—**Nicolas Menchikoff**: The Devonian containing cephalopods of Oued Saoura and the chains of Ougarta (Sahara).—**Maurice Blumenthal**: The stratigraphic material of the Bokoya stratum.—**Maurice Suess**: The presence of gastropods and of vertebrates in the Bou Hanifia grit, Hascara sheet (Oran).—**G. Depape**: The Tertiary plants of Wei-tchang (China).—**Paul Becquerel**: The anhydrobiosis of the tubers of *Ranunculus* in liquid nitrogen.—**Pierre Chouard** and **Georges Teissier**: Variations in the intensity of growth in melon seedlings in the course of development as a function of the amount of available reserves.—**J. Chaine** and **J. Duvergier**: The differentiation of fishes of the genus *Ophidium* by their otoliths.—**Mlle. M. Friant**: The abrasion of the molars *in utero* of rodents of the Caviideæ.—**Raymond-Hamet**: The natural classification of the amines similar to adrenaline. The suggested classification is based on the vascular action of maximum doses of the amines.—**Fernand Mercier**: The influence of the intrarachidian injection of cocaine or its substitutes on the cardio-vascular action of

adrenaline.—**R. Monceaux** and **H. Godard**: The presence of tyrosine and of other free amino-acids in a nævocarcinoma without pigment.—**Maurice Piettre**: Casein complexes. Calcium caseino-phosphate in milk. Reply to a criticism by Porcher and Brigando. —**Jean Caminopetros**: The sensibility of the spermophil *Citillus citillus* to icterohæmorragic spirochetosis.

CAPE TOWN

Royal Society of South Africa, May 18.—**H. G. Fourcade**: Contributions to the flora of the Knysna and neighbouring divisions. In preparing a list of the flowering plants found in the divisions of George, Knysna, Humansdorp, and Uniondale, based chiefly on his own collections at intervals during many years, the author wished to include the new species collected by himself that were still undescribed, and with this object has supplied their description in the paper. He has added the name changes in his list that have been rendered necessary by the international rules of botanical nomenclature. In testing the numerous new combinations that have already been made by others since the publication of the "Flora Capensis", a number of illegitimate changes were found, and these are rectified whenever they relate to species included in the compiled list.

Forthcoming Events

WEDNESDAY, JULY 20

BRITISH MEDICAL ASSOCIATION (Fourth Victor Horsley Memorial Lecture at University College Hospital Medical School, Gower Street, W.C.1.).—Prof. E. D. Adrian: "The Visceral Sense Organs," at 5 P.M.

Conferences

JULY 23–30

BRITISH MEDICAL ASSOCIATION (London) Centenary Meeting.

Science and Social Economics

THOUGH it is recognised that science touches the life of society closely at many points, there are other spheres in which the contribution of science is only just beginning to be perceived. The full effect of the changes in the structure of society, whether in Great Britain or elsewhere, produced by the impact of applied physical science in such ways as the increased facilities for transport over great distances; rapid long-range communication by telephone, wireless, aeroplane; the cinema and broadcasting; and the spread of mechanical production on a large scale in such parts of the world as India, China, and Russia has yet to be perceived. The extent of the influence of these forces or the magnitude of the changes they have produced will undoubtedly be vast but are largely unpredictable. Least of all can they be ignored in a country like Great Britain.

It is largely because of this that authorities like Prof. W. McDougall have attributed much of the responsibility for our present position to our neglect of the social sciences, and have pleaded for the direction of our most powerful intellects from research in the physical sciences into research on the biological, the human and the social sciences. In this manner it would become possible to build the social sciences and especially the science of economics on the basis provided by anthropological research.

There is thus visualised a further wide field in which science can make a contribution of vital importance to the development or even the existence of society. As a balance to the violent changes produced directly or indirectly in our social or industrial life by physical science, there would be accumulated an adequate volume of scientific knowledge of human nature and the life of society which would facilitate the adjustment of our social, economic, and political life in a rational way and apart from sectional prejudices. The development in this way of economics, politics, jurisprudence, criminology, etc., on a basis of facts and a sound or scientific psychology, would afford sure guidance in dealing with the many difficult problems which confront us in national administration, finance, unemployment, trade cycles and international relations to-day.

We have already attempted in administration of the backward races the experimental application of biology or psychology to problems of national and international conduct, and the success achieved indicates the value which such

methods, when widely applied and based on a firm foundation of adequate research, can have in dealing with the racial relations and the evolution of co-operation in place of competition. The confusion which exists in economics to-day is not due to the absence of statistical facts but to our lack of scientific knowledge of imponderable psychological factors having their basis in human energies, in the personal and group loyalties of men, their fears, their ideals, passions, and ambitions. Only by patient research leading to the gradual development of exact knowledge can the world hope to win a more perfect control over the economic organisation resulting from the mechanical mass production made possible by the rapid progress of physical science in the last century.

The contrast between the comparative freedom with which scientific knowledge and development have influenced industrial development and their almost negligible influence in the control of national and international policies which so largely determine the development or stagnation of industry and society as indicated above is startling, and the danger grows. It must not be imagined, however, that science or scientific research offers a ready-made solution of all our present difficulties, or indeed that it is more than one factor in the solution of our national social and industrial problems. It is claimed, however, that in the modern State the problems of national life to an increasing extent involve scientific factors, and cannot be handled aright without scientific knowledge. There can be no adequate control unless the full facts of the situation are taken into consideration and accurately appraised by those competent to assess the scientific aspects along with other factors.

As has often been stated in these columns we need an increasing number of administrators who count among their qualifications a first-hand experience of scientific technique, and a scientific outlook is as essential in national affairs as in industry, if the resources and contribution of science are to be utilised to full advantage. Recent experience indicates that this is likely to be an essential condition of progress. The comparative impotency of Parliament in the present industrial situation is largely due to its lack of inherent scientific and technical knowledge, as well as to the absence of such knowledge in those holding high administrative appointments in the civil service. No severer handicap has been imposed on Great Britain in the present crisis than the exclusion, often deliberate, of technical and scientific men of administrative ability from responsible administrative posts in industry or in Government service. Not until this defect is remedied in Parliament, as in Government service and industries generally, can we expect to see not merely effective and scientific reorganisation of our industries from the point of view of the nation as a whole, but also the initiation of the task of wise international co-operation in a spirit of unselfishness and world service.

The possibilities of the application of scientific method in national and political affairs are indicated by the success of those pieces of reconstruction work in post-War Europe which were based on an impartial scientific analysis of the problem by relevant experts and linked up with the appropriate action. The Austrian and Hungarian reconstruction schemes and the Greek Settlement scheme are examples of a new technique in international affairs, and demonstrate convincingly the function of the technical expert in linking up knowledge and power. The Dawes and Young Commissions are similar examples of this new method of applying the forces of science and expert skill and wisdom to problems declared insoluble by governments and hopelessly vitiated by human prejudice. That their solution was only temporary, and that the problem threatens to be sucked once more into the maelstrom of politics, merely indicates the imperative need for extending this same technique to national and international problems of disarmament, tariffs, reparations, and War debts, etc., which react on the issues involved.

The application of scientific method to the unemployment problem and other industrial or economic difficulties has been further suggested not only in the Macmillan report, which, apart from its assertion that the task of capital development should be attempted in a much more systematic and far-sighted manner than hitherto, visualised a comprehensive rebuilding and replanning policy for our larger towns and industrial centres, the replanning and refitting of staple industries, and the electrification of railway systems, but also by the International Labour Office in its proposals for practical action on unemployment in Europe, which were recently submitted to the Commission of Inquiry for European Union. Without elaborating a definite scheme, the memorandum outlines such ideas as a definitely planned international road system to meet the present-day requirements of rapidly increasing motor traffic, and to provide connexions between the special roads for motor traffic which are at present being constructed everywhere independently in the most advanced countries of Europe; the co-ordination of regional

systems of navigable waterways; the international distribution of electric power, and the concerted and uniform substitution on all European continental railways of a suitable system of automatic coupling in place of the present screw couplings, which are annually responsible for many fatal accidents.

Schemes of this type planned in advance as a definite programme would enable public works to be postponed from a boom period and carried out in a time of depression. They should thus be of direct value in reducing the incidence of unemployment as well as in encouraging the spirit of European co-operation on which the Macmillan report laid such stress.

There is indeed much evidence of a widespread recognition that an era of conscious and deliberate management must succeed the present era of undirected natural evolution. Scientific workers themselves have urged support of leaders who would attempt to plan the reconstruction of the world on the basis of a definite five-year or similar plan.

General Smuts's plea that the scientific expert and his report giving a just and impartial lead to governments should be regularly accepted just as judicial decisions are accepted, as a matter of course, is perhaps less visionary than when it was uttered, and the value of the mature, sober, impartial spirit of science in the functioning of our national and international system may be the nearer recognition because of the present chaos. Sections of the community are disposed to accept the leadership of science, and to adopt a well thought out and comprehensive scheme of national and international reconstruction based upon an authoritative and scientific analysis of the whole situation.

The participation of the scientific worker in this task of reconstruction on equal terms with representatives drawn from other sections of the community should at least enable us to relate administrative action to the full facts of the situation, shatter the influence of prejudice or sectional interests in determining national policy, and bring to an end those gigantic forms of national and communal waste which largely are the result of ignorance on the part of our administrators. Above all, it would ensure that human values and human factors, the neglect of which is responsible for so many of our present difficulties, receive full and sympathetic appraisement because as a result of scientific study they are at last adequately understood.

Bibliographia Zoologica

An Introduction to the Literature of Vertebrate Zoology: based chiefly on the Titles in the Blacker Library of Zoology, the Emma Shearer Wood Library of Ornithology, the Bibliotheca Osleriana, and other Libraries of McGill University, Montreal. Compiled and edited by Dr. Casey A. Wood. Pp. xix + 643. (London: Oxford University Press, 1931.) 63*s*.

THE publication of this imposing volume suggests a consideration of the more important resources already available. For the older literature, that is, up to 1776, we must still rely on Haller's "Bibliotheca Anatomica", which would be an enduring monument to the memory of that remarkable man even if it did not represent but a fraction of his stupendous labours. For the later work there is so far nothing to beat Carus and Engelmann and its continuation by Taschenberg, although the utility of the latter part is sadly discounted, if not destroyed, by the lack of the indexes, which latter, we are informed, are not to be printed—a lamentable decision on the part of the famous German publishing house responsible for the work.

Of works on private libraries, Dryander's catalogue of Sir Joseph Banks's collection is by far the most useful, and is worth its weight in gold. The most distinguished example of the catalogues of public institutions is that of the Natural History Museum at South Kensington—a library not rich in the older literature but containing almost everything else. This catalogue is a masterpiece of bibliographical research, as we had a right to expect from two such adepts as Bernard Woodward and Davies Sherborn. The format of the work under review has been based on the South Kensington example, and no better model could have been selected. The Royal Society's catalogue arouses very mixed feelings. Whilst it would have been easy to have improved this work without materially increasing the cost of compilation, it is, nevertheless, indispensable to every student of the literature of science. The first three series can be obtained in the second-hand market at quite a reasonable cost, but the last series of seven volumes, bringing the work down to 1900, is published at more than £41—a price which rules out the private purchaser and, for that matter, most institutions. On what principles of business and equity this can be justified it is difficult to see.

A work which catalogues any single private or

public library, unless that library be an exceptionally large one, has always one defect and one merit. Its defect is that it is necessarily incomplete, but its merit is that, so far as it goes, it is reliable, since every entry has been written with the work to which it relates in front of the recorder. A compilation, on the other hand, is bound to repeat the errors and misprints of previous compilations. For example, it is generally found that the mistakes in Agassiz' "Bibliographia Zoologiæ" are directly inherited from Boehmer. We must therefore be careful to distinguish between an original bibliography and a second-hand compilation, since it is sound procedure to neglect the latter wherever possible. Dr. Casey Wood's catalogue, however, is a worthy example of the former class of work, and convinces us that the library of the premier University of Canada, at all events so far as zoology is concerned, must be a remarkably fine one. It must not be forgotten, also, that it was to McGill University that the late Sir William Osler bequeathed his own magnificent collection of early medical and anatomical works, some of which figure in the present catalogue.

Dr. Wood has divided his work into three sections. The first (146 pages) is a review of the literature of vertebrate zoology as represented in the McGill libraries up to the year 1930. The second (26 pages) comprises three indexes, which enable the reader to trace works published at specific dates, and those relating to particular geographical regions and to the larger zoological groups. The third section (469 pages) is the alphabetical list of titles. Sections 1 and 2 serve as a very useful introduction, and convert what would otherwise be a mere list into a serviceable guide. Here we find chapters dealing with the beginnings of zoological literature and with the medieval and modern periods. These chapters are brief but informative, and are to be regarded as skeleton outlines for the benefit of the inexperienced rather than as original contributions to the history of zoology. The whole work is a valuable addition to the bibliographical resources of the working zoologist, and Dr. Casey Wood has earned our thanks for reducing so useful a catalogue to the accessibility of print.

Unhappily, with the single notable exception of Edinburgh, universities cannot afford the luxury of printing their library catalogues, but no one can doubt that, were they able to do so, the gain to learning would be considerable. Of the great national libraries of France, England, and Germany, the publication of the French catalogue alone is rapidly approaching completion, but the printing of the English and German catalogues has only just begun, and at the present rate can scarcely be completed within fifty years.

In glancing at Dr. Wood's volume we noticed a number of slips, amongst which were the following: P. 23—Rommel's De Fœtibus (1680) is nothing more than a crude description of a case of abdominal pregnancy and has no embryological interest. P. 42—Haller's connexion with the "Historia Ranarum" (1758) is purely nominal. This beautiful and important book was entirely the work of Roesel. The entry under Haller on p. 375 should be deleted, and that under Roesel on p. 541 retained. P. 43—Bonnet was not the discoverer of parthenogenesis in Aphidæ, but Leeuwenhoeck in 1695. P. 104—Boussuet's "De Natura Aquatilium" (1558) is a metrical version of Rondelet and not a supplement to it. On p. 541 the French translation of Rondelet is wrongly stated to be "probably of Boussuet's edition". It has no relation to Boussuet whatever. Also, why query the place of publication, when it is clearly given on the title-page? Pp. 196-7—where the authors of anonymous works are known, they should be indicated. Thus the catalogue of the Ashmolean is by P. B. Duncan and the "Mémoire instructif" is by E. F. Turgot. On p. 604, what appears to be another copy of the latter work is catalogued under Turgot. P. 325—Dryander's catalogue of Banks's library is asserted to have "passed through half a dozen editions". Only one edition of this work was published. What is evidently referred to is the "Catalogus librorum qui desiderantur in bibliotheca J. Banks"—obviously another story. The entry under Banks on p. 220 is correct except that for 1798 read 1796. P. 430—the Dutch edition of Leeuwenhoeck is not a complete set of all his works, neither was he a physician. A number of his important contributions to the *Phil. Trans.* do not appear in the collected works, Dutch or Latin. P. 498—Oken's "Allgemeine Naturgeschichte" is interesting only as an example of the complete potboiler, but as a piece of zoological literature it is neither rare nor important. P. 520—the work catalogued under Pitfeild is not by this author but only translated by him. Nor is it correct to say that this work is not in the South Kensington catalogue, where it is to be found under "Paris", and Pitfeild's name, as usual, is incorrectly spelt. P. 589—"The Book of Nature" does not include Swammerdam's works on respiration and on the structure of the uterus, and does not therefore constitute his *Opera omnia*.

F. J. COLE.

A Modern Domesday Book

The Victoria History of the County of Kent. Edited by William Page. Vol. 3. Pp xv + 452 + 37 plates. (London: The St. Catherine Press, 1932.) 63*s*.

WITH the issue of the third volume, the general section of "The Victoria History of the County of Kent" is brought to a close; the remaining volumes, comprising the topography of the county, will deal with the history and topography of the individual parishes.

When a county has so much that is of moment to the archæologist and the historian, it may seem profitless to compare one volume with another. Each has its special attraction for different classes of reader. Here undoubtedly the most considerable contribution is the account of the Roman remains, which include the site of Richborough, of the first importance for the final phase of the Roman occupation. This has been completed by Dr. R. E. Mortimer Wheeler, partly from material which had been brought together by the late Prof. Haverfield and Miss Marjorie Taylor. Romano-British Kent, as a main line of communication with the Continent, is of exceptional interest. Dr. Wheeler's article in its combination of description and historical reconstruction is a model for the treatment of archæological material in a work on this scale and of this character. The somewhat disappointing material afforded by the Domesday survey, with which Prof. N. Nielson and the Rev. F. W. Ragg deal, is more than counterbalanced by the interesting "Domesday Monachorum", again the work of Prof. Nielson. Both Miss Maud Simkins, in her survey of the political history, and Dr. Gilbert Slater, on the social and economic conditions, handle their material with a due appreciation of its relation to the character and purpose of the whole work as a county record. In an informative account of the industries, Miss Ethel M. Hewett has included a history of the coal mining project which takes a hopeful view of its future prospects.

It may not be out of place to recall that the first volume of "The Victoria History of the County of Kent", which dealt mainly with natural history and archæology, appeared so long ago as 1908, while the second volume, of which the principal topic was ecclesiastical history, appeared in 1926. The long interval which has elapsed since the publication of the first volume is to be deplored; but it was inevitable in the unforeseen conditions which arose.

The "Victoria History of the Counties of England" was begun in 1899 under the general editorship of Sir Laurence Gomme and Mr. H. A. Doubleday and since 1902 has been in charge of Mr. William Page. It was dedicated to Queen Victoria, who commanded that it should bear her name, and it has been continued as a memorial of her. It was planned on a grand scale as a national historical survey which would be of permanent interest and value. It includes not only natural features, flora and fauna, antiquities, a new translation of Domesday Book, and political, social, and economic history, but also in each county, under the final section of topography, there is a detailed description and history of each parish, with an account of the land and its owners from the Conquest, or before, downwards. This section has entailed a research in manorial and family histories and records, in which no effort has been spared to secure that it should be exhaustive. This alone will make of the Victoria Histories a treasure-house of facts of much more than local significance. It is, however, no exaggeration to say that from any point of view the "Victoria History of the Counties of England" is a work of national importance.

When publication was interrupted at the outbreak of war in 1914, 71 volumes had been issued, and a large amount of material for future volumes had been prepared. That an undertaking of this magnitude and character should have been carried so far without assistance from outside reflects the greatest credit on editor, staff, contributors, and publisher. The increased cost of production after the War precluded the continuation of the work until the generous assistance of Viscount Hambleden enabled publication to be resumed in 1927. Unfortunately, this assistance is no longer available, and until support is obtained from other sources it will not be possible to carry on the preparation and issue of further volumes.

In view of what has been said as to the character of the work and the field it covers, it is abundantly evident that its continuation does not fall short of being a matter of national concern. Even if in present conditions help from the national exchequer is out of the question, the counties directly concerned might well assist, especially where attempts are being made to arouse interest in local history as part of the curriculum of the county schools. Perhaps this, too, may seem to take too optimistic a view. In that event, the work is such as should present a strong appeal to any one of our universities. Not only would a university which assumed responsibility for the Victoria County Histories, issuing the volumes through its university press, confer a lasting benefit on academic

studies in several branches of history and science, but it would also provide an exceptionally favourable field for its research workers in the collection and preparation for publication of material under the supervision of those departments of the university whose subjects come within the scope of the "History". Too much time, thought, and money have been expended on the work so far as it has gone for it to be allowed to come to premature end without some strenuous effort to secure its successful completion. Even if it be too much to expect in these difficult days that sufficient support for the completion of the work will be forthcoming, it is greatly to be hoped that steps will be taken to preserve for research purposes the vast amount of material which has been collected from original sources for various volumes of the "History" yet unpublished.

The Future of China

The Capital Question of China. By Lionel Curtis. Pp. xix + 322. (London: Macmillan and Co., Ltd., 1932.) 10*s.* 6*d.* net.

MR. LIONEL CURTIS has done a public service in writing this book. It treats of the plight of at least a fifth of the human race, to whose condition our past actions have demonstrably contributed. It traces the effects of a leaven of modern scientific thought, working in a society not socially or politically organised to receive it. It gives a short but adequate survey of the antecedents, and makes a few tentative suggestions for ameliorative action. Here, no doubt, the reader will feel the need of further guidance; but, as Mr. Curtis insists again and again, the first essential is that we in the West, and especially the British and American peoples, should take an increasing interest in the matter and inform ourselves as to the state of affairs.

This purpose the book admirably fulfils, and, as our more immediate concerns in the West become less harassing, we shall be able to turn with a calmer and more united mind to the even larger problems which the future of China unfolds. But every one should read the book without delay, if only to revive his memory of recent events and put them in the right setting of world-history at the most crucial meeting point of East and West. Three lines of contact have persisted since the middle ages and have been much extended in modern times: trade, which has led to the foreign concessions and 'unequal treaties'; religion, which has been steadily and heroically promoted by Christians of all sects, with good humanitarian results, but without increasing the political stability of the country; science, which in recent years has been eagerly studied by the élite of the younger generation, and is the strongest revolutionary force. All this has gone on without the political training which Rome afforded in the ancient world and England has given to India and other parts of the modern world.

Mr. Curtis deals briefly but fairly with the Manchurian question and the claims and recent actions of Japan. He stands firmly for the essential unity of China, and holds that Japan will live to regret her 'gunboat' policy. The two definite suggestions which he makes for British policy are: that we should set up our legation in close contact with the Chinese government, the place being somewhere in the Yangtze valley; secondly, that we should send out some one of full diplomatic standing and the highest personal qualifications to advise and co-operate with the Chinese central authorities. Cromer and Milner suggest to him the desirable type among English administrators; Dwight Morrow, whose work in Mexico had no proconsular touch, seems a nearer analogy. But the problems of Mexico are child's play in comparison; China is an ancient world thrown into chaos.

F. S. MARVIN.

Short Reviews

Witwatersrand Mining Practice. By Prof. G. A. Watermeyer and S. N. Hoffenberg. (Published by the Transvaal Chamber of Mines, Gold Producers' Committee.) Pp. xxxii + 895. (Johannesburg: Hortors, Ltd., 1932.) 45*s.*

THE Mines of the Witwatersrand have produced gold worth more than £1080 millions sterling, and their annual output is half the annual world production of gold. The underground practice of so important a field, which contains some of the deepest mines of the world, is of interest to all mining engineers, especially as within the last decade great advances have been made in underground working methods, as a result of exhaustive research by the mining groups.

This volume contains up-to-date descriptions of all branches of Rand underground practice. The aim of the authors has been to provide a work which would serve both as a reference book to the mining engineer and a textbook for the student. The first objective has been achieved, for the abundant technical data, the clear illustrations, and good index make the volume of great service to those wishing to keep abreast of modern underground practice on the Rand, without the inconvenience of consulting the transactions of a number of different technical societies. In order to serve as a textbook of mining with special

reference to Witwatersrand practice, many of the chapters have been provided with introductory matter to treat each subject in a connected manner. It is difficult to combine the amount of detail desirable for a handbook of reference with the breadth of treatment needed for a textbook. From the point of view of a textbook, the chapters on underground methods of working could have been improved by a broader review of the methods described. T. P.

Merchant Venturers in Bronze. By H. Peake and H. J. Fleure. (The Corridors of Time, 7.) Pp. viii + 168. (Oxford: Clarendon Press; London: Oxford University Press, 1931.) 5*s*. net.

IN "Merchant Venturers in Bronze" the authors of "The Corridors of Time" have now come to the early and middle bronze age. At the beginning of this period, somewhere about 1900 B.C., the fall of Hissarlik, as they interpret the evidence, caused a dislocation of the trading activities radiating from the Troad, but by no means interrupted the spread of a knowledge of bronze. The argument for the localised development of culture already put forward, in the case of outlying areas visited for the supply of metal, is here carried further in its application to western Europe.

The period covered, which extends over the greater part of the second millennium, is one of special interest, as it comprises not only the extension of the use of bronze in central Europe—of which the account given here may, perhaps, appear to make light of difficulties, though with some success—but it also embraces the great racial movements of the Aryans into India, the Kassites into Mesopotamia, and the Hyksos into Egypt. It has also to deal with the foundation of the Mycenæan civilisation and with the numerous problems to which the origin and early development of that civilisation gives rise, such as, for example, the chronological and cultural relation of the tholos tomb and the shaft-graves of Mycenæ, a problem for which an ingenious solution is suggested. The period is a maze of difficulties; and if the size of the volume precludes very detailed treatment, it does at least serve as a guide along the darker stages of the way.

Engineering Mechanics. By Prof. F. L. Brown. Pp. xi + 477. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1931.) 20*s*. net.

THE book is written from the point of view of the engineering student, and the applications of the principles of mechanics are treated conformably with engineering practice. Thus the examples are drawn from roof trusses, bridge girders, journal bearings, pump impellers, automobile engines, and the like. Applications in other directions are ignored as inappropriate. The subject matter is clearly expounded, with many well-executed diagrams which should render the text easy to assimilate. The usual ground is covered in two parts, the first dealing with statics and the second with kinematics and kinetics. The author makes a point of omitting any reference to the term 'mass' in the development of the last-named subject until after he has restated and explained Newton's Laws of Motion independently of it. Indeed, he avoids the use of the word throughout, urging that it is not essential to the elucidation of problems which particularly concern the engineer. Appended to each section of explanatory text is a selection of illustrative examples, with solutions or answers. With its modern instances, the book is thoroughly up to date, and should prove useful to the engineering student. B. C.

A Practical Manual of Lac Cultivation. By P. M. Glover. Pp. iv + 81 + 16 plates. (Nankum, Ranchi: The Indian Lac Association for Research, 1931.) n.p.

IN view of the importance of the lac industry to the Indian Empire, it is obviously desirable that the best practical information should be readily accessible to all who seek it. Mr. P. M. Glover, entomologist to the Indian Lac Research Institute at Ranchi, has produced an up-to-date guide to the subject, embodying the results of recent investigation carried out under the auspices of the Lac Research Institute, which will doubtlessly be welcomed by all the more progressive growers. The yield of the lac crop responds enormously to judicious inoculation and skilful cultivation, coupled with proper pruning of the host trees. Unfortunately, the lac insect itself has numerous enemies, and some of the most destructive are other insects of several kinds. The counteraction of the activities of such enemies is one of the most urgent problems that have to be faced, since they are responsible for the destruction of about sixty per cent of the crop produced in each year. These and other aspects of lac cultivation are discussed by Mr. Glover in his very practical guide to the subject.

Check-List of Birds of the World. By James Lee Peters. Vol. 1. Pp. xviii + 345. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1931.) 17*s*. 6*d*. net.

A SINGLE work giving a complete list of the birds of the world had not been published for more than thirty years, during which time very many new forms had been described and much revision had been made in classification and nomenclature. The list which Mr. Peters, of the Harvard Museum of Comparative Zoology, is compiling, and of which this is the first of ten volumes, will therefore be an invaluable work of reference for ornithologists if the remainder of the task can be accomplished without too great delay. The information given is restricted to the names of the genera, species, and sub-species, the authorities for these, abbreviated synonymies, and summaries of the distribution of each form. On many controversial points of nomenclature and validity the author has necessarily had to follow his own judgment, but apart from differences of opinion in this regard, there is likely to be little criticism of the way in which he has begun his great labour. The arrangement and the typography are admirably clear.

The Total Solar Eclipse of Aug. 31, 1932

By Prof. F. J. M. STRATTON

THE belt of totality of the solar eclipse of Aug. 31, 1932, starts north of Siberia, and, after passing within about 300 miles of the north pole, crosses Canada and New England, and ends in the middle of the Atlantic Ocean. In Canada the track runs from the southern end of Hudson Bay south-east across Quebec, the central line crossing the St. Lawrence River at Yamachiche, where there is a Marconi wireless station (Fig. 1). The south-westerly boundary of the belt of totality passes

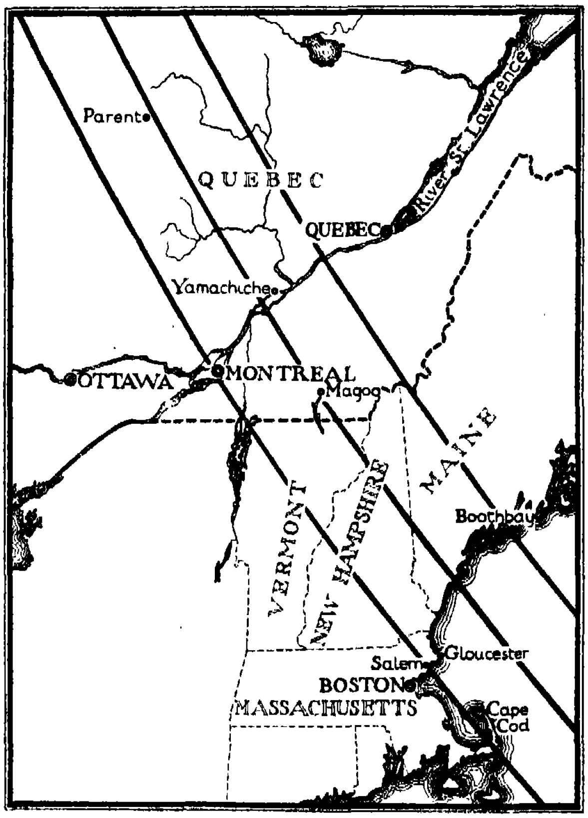

FIG. 1.—Track in Canada and New England of the total solar eclipse of Aug. 31, 1932.

through Montreal, and reaches the Atlantic coast between Salem and Gloucester; Boston is outside the belt, Cape Cod within it; the north-eastern boundary reaches the coast close to Boothbay in Maine.

Observations of the weather conditions between Aug. 16 and Sept. 14 at the hours of the eclipse have been made for a number of years at more than a hundred stations. Prof. F. Slocum, following Prof. D. Todd, has organised this work for the past five years and discussed the results (see NATURE, May 3, 1930, p. 673). There is no very marked difference between conditions in different sections of the track, and everything points to equal chances at any station that may be selected.

No details are available of the plans of the various American eclipse parties which will be distributed through Vermont, New Hampshire, and Maine, but it is understood that Prof. S. A. Mitchell, of the Leander McCormick Observatory, will be stationed at Magog in southern Quebec. Three British expeditions are being sent to Canada under the auspices of the Joint Permanent Eclipse Committee of the Royal Society and the Royal Astronomical Society. Dr. J. Jackson and Mr. C. R. Davidson, from the Royal Observatory, Greenwich, will join Prof. Meldrum Stewart, of the Dominion Observatory, Ottawa, at Parent, a station on the Canadian National Railway north of the St. Lawrence River; Prof. H. Dingle, of the Imperial College of Science, will work at the Macdonald Physics Laboratory of McGill University in Montreal, on the edge of the eclipse belt; Prof. F. J. M. Stratton, Dr. R. O. Redman, and Mr. C. P. Butler, of the Solar Physics Observatory, Cambridge, with Prof. J. A. Carroll, of the University of Aberdeen, will be stationed at Magog in southern Quebec. They will be joined by Dr. J. S. Foster and Miss Douglass (and possibly several others) from McGill University, Prof. G. H. Henderson, of Dalhousie University, Dr. C. S. Beals, of the Victoria Observatory, and by several of those who are making the preliminary tour of Canadian and American observatories, organised by the assistant secretary of the Royal Astronomical Society; among others, the master of Caius, Dr. F. W. Aston, Dr. W. Hall, Dr. Haughton, Dr. H. Knox-Shaw, Dr. W. J. S. Lockyer, Dr. W. H. Steavenson, and Mr. A. D. Thackeray are expected to join the Cambridge party, and to help in the observations of the eclipse.

The programmes of the three British expeditions are as follows:

(1) The Greenwich expedition will take photographs of the corona with the 6-inch lens of 45 ft. focal length lent by Mr. Worthington for use at the eclipse at Alor Star in 1929. Objective prism spectra of the chromosphere and of the corona will be secured with a telescope of 7 in. aperture and 21 ft. focal length, with a 45° prism placed before the object-glass. The range of spectrum on a curved film will be from $\lambda 3600$ to $\lambda 6800$. A fourth attempt will be made — the previous attempts having been frustrated by bad weather conditions —to obtain a comparison of the intensities of the *H* and *K* lines with those of the Ca^+ triplet at $\lambda 8600$ at different heights in the chromosphere. The remaining instrument is to be a grating slit spectrograph, which will be used for a study of the spectrum of the chromosphere and corona from $\lambda 4500$ to $\lambda 9000$—the dispersion will be 17 A. to the mm. All the four instruments will be fed with beams from cœlostats.

(2) Prof. Dingle's objects at this eclipse are to study the bright line spectrum at the cusp with high dispersion, and the Fraunhofer spectrum at

the limb just before and just after totality. Prof. H. F. Newall and Prof. A. Fowler, from observations made in England at the eclipse of April 1912, showed what interesting results might be expected from observations of a nearly total eclipse or from observations at the edge of the belt of totality, confirming suggestions made by Mr. Evershed in 1903. Hitherto bad weather has frustrated all attempts to carry out such investigations, while the interest of the problem has only been increased by the study of spectral changes in wave-length at the sun's limb. Prof. Dingle is using a Littrow spectrograph with two 60° prisms backed by a plane Rowland grating (used in the first order), working with a 4 in. lens of 16 ft. focal length. The region of the spectrum to be examined will be λλ4200-4400, with an average dispersion of 0·6 A. per mm. The limb will be studied for about five minutes each side of totality, and the cusp for about half an hour beforehand and half an hour afterwards.

(3) The programme of the Cambridge expedition will be mainly a repetition of investigations prevented by clouds at the eclipses of 1927, 1929, in Norway, Siam, and Kedah. The polarisation of the corona will be studied by a double tube camera of 54 in. focal length, with a large nicol prism placed in front of one tube. The dependence of the polarisation on wave-length will be examined by a double-image one-prism spectrograph fed by an image-forming lens of 2 ft. focal length. The Hills quartz spectrograph will be used for a study of the ultra-violet spectrum of the chromosphere, with especial reference to the intensities at varying solar levels of the lines of the Balmer series and of the continuous spectrum at the head of the series. In the case of the corona, the chief study with this instrument will be the distribution of the radiation of the continuous spectrum. The results obtained with this spectrograph will be checked by a spectrum of different dispersion obtained from a 6 in. concave Rowland grating, used in the stigmatic position with a reflecting collimator. The range of spectrum to be covered will be λλ3200-4600.

The continuous spectrum of the outer corona will be studied with a 19-inch Common mirror of 50 in. focal length and a one-prism spectrograph with Aldis collimator and camera lenses of aperture 4 in. working at *f*/3. An objective interferometer will be used to study the wave-length of the green coronal line and movements in the coronal gases, in particular the rotation of the corona. The latter problem will also be attacked with the 4-prism spectrograph mounted on a polar-heliostat and used for that purpose by Prof. Newall in Sumatra in 1901.

A moving plate objective grating spectrograph with a slit in the focal plane radial to the sun's limb will be used for spectrophotometric study of the flash spectrum at different levels over the range λλ4100-4700. The grating will be a 6 in. plane grating fed by a Cooke photovisual lens of 6 in. aperture and 20 ft. focal length. A second objective grating will, it is hoped, be used for plates stained with xenocyanin and sensitive over the range λλ8600-10600, while a slit grating spectrograph will be used with plates stained with mesocyanin for the region centred at λ8600. The various instruments are being fed with beams from two cœlostats and Sir Francis McClean's 21-in. siderostat. The Hills siderostat will be used by the observers from McGill University for a grating spectrograph of high light-gathering power.

Finally, the 8 in. cœlostat of the Royal Irish Academy will feed the 4 in. lens of 19 ft. focal length lent by the same body, to secure direct photographs of the corona, and the 4 in. direct-vision prism of the Royal Observatory, Edinburgh, will be placed in front of the lens at the beginning and end of totality for objective-prism spectra of the flash, while Dr. Lockyer will take direct photographs of the corona with a camera lens of 4 in. aperture and 28 in. focal length.

The Lucasian Professors at Cambridge

THE Lucasian professorship of mathematics at the University of Cambridge, from which Sir Joseph Larmor retires at the end of September after holding it with distinction since 1903, is the third oldest chair of mathematics in Great Britain. The chair of geometry at Gresham College, London, was founded in 1596, the Savilian professorship of geometry at Oxford dates from 1619, while the Lucasian chair was founded in 1663, the same year in which the Royal Society received its second charter. It was founded through a bequest by Henry Lucas, who had studied at St. John's College, Cambridge, and after having served as secretary to the Earl of Holland, chancellor of the University, was elected to represent the University in Parliament. In his will he directed his executors to purchase land to the value of £100 a year to provide for the stipend of a professor of mathematics. Lucas died in London on July 22, 1663, and that same year the deeply learned and much travelled Rev. Isaac Barrow (1630–1677), already professor of Greek and Gresham professor of geometry, and afterwards master of Trinity, was elected first Lucasian professor.

Barrow took his duties seriously from the first, and immediately after his appointment, " the better to secure the End of so noble and useful a Foundation, he took Care that himself and his Successors should be obliged to leave, yearly, to the University ten written lectures ". His opening oration was delivered on March 14, 1664, and the lectures he gave during the next five years formed the substance of his " Lectiones Opticæ et Geometricæ ", 1669, and his " Lectiones Mathematicæ ", published six years after his death. But divinity had stronger claims for Barrow than even mathematics, and having already seen and acknowledged the superior abilities of his pupil Newton, in 1669 he resigned in his favour.

Newton was twenty-seven years of age when

he became Lucasian professor, and he held the chair for thirty-four years, until in 1703 he became president of the Royal Society. It is unnecessary to say that it was during his years at Cambridge that all his greatest discoveries were made and his greatest works published. Some of his discoveries were first made known through his lectures. "During his tenure of the professorship", says Ball, "it was Newton's practice to lecture publicly once a week, for from half an hour to an hour at a time, in one term of each year, probably dictating his lectures as rapidly as they could be taken down. . . . He never repeated a course, which usually consisted of nine or ten lectures. . . . The manuscripts of his lectures for seventeen out of the first eighteen years of his tenure are extant."

Newton was elected Parliamentary representative for the University of Cambridge in 1688, and after that lectured but little. In 1699 he made Whiston his deputy, and four years later Whiston was appointed to the chair.

With Newton's resignation and his removal to London, mathematical studies in Cambridge suffered a loss which the University felt for very many years. "Newton's burst of illumination", wrote the late Prof. H. H. Turner, "was followed by a dark century in Cambridge mathematics which is painful to contemplate." Yet in spite of this, the chair on which Newton had shed so much lustre continued to be held by men who at least had a deep reverence for his character and his work, and each of whom in his turn did something to advance the progress of science.

William Whiston (1667–1752), the first of the five occupants of the Lucasian chair during the eighteenth century, had graduated at Clare Hall and at the time of his appointment was rector of Lowestoft. Something of his activities can be gleaned from his own whimsical memoirs. As Lucasian professor he was instrumental in getting Roger Cotes (1682–1716) made the first Plumian professor of astronomy, declaring that in mathematics he "was but a child to Mr. Cotes", and in 1707 with Cotes he began a course of philosophical experiments. But Whiston's period of office was cut short through his religious views being held obnoxious by the authorities, and on Oct. 30, 1710, he was expelled from the University. The loss of £100 a year was, no doubt, felt severely, but thanks to Addison and Steele he was able to give astronomical lectures "at Mr. Button's Coffee house, near Covent Garden, to the agreeable entertainment of a good number of curious persons and the procuring me and my family some comfortable support under my banishment".

The choice of a successor to Whiston fell on Nicolas Saunderson (1682–1739), who through smallpox had been blind from the age of one, but who was described by one of his students as "a professor who had not the use of his own eyes, but taught others to use theirs". He was one of the earliest exponents of the Newtonian philosophy and, it is said, spent seven or eight hours a day in teaching. His "Elements of Algebra", compiled during the last six years of his life, has been referred to as "a model of careful exposition". John Colson (1680–1760), who succeeded Saunderson, was already fifty-nine when appointed to the chair; he had had as a competitor Demoivre, the intimate of Newton, who, however, was seventy-two, "almost as much fit for his coffin; he was a mere skeleton, nothing but skin and bone". In 1736, Colson had published a work on fluxions, and during the twenty-one years he held the Lucasian professorship he translated Nollet's work on experimental philosophy and Maria Gaetana Agnesi's "Istituzioni analitiche", but, said Cole, the Cambridge antiquarian, "the University was much disappointed in its expectations of a professor that was to give credit to it by his lectures".

When Colson died in 1760 at the age of eighty years, the example of Barrow and Newton was no longer followed, and neither Edward Waring (1734–1798) nor Isaac Milner (1751–1820), his successors, gave lectures or enriched the University with their writings. Waring was only twenty-five years of age when given the Lucasian chair. Afterwards he qualified in medicine and obtained a seat on the Board of Longitude, but his European fame was due to his "Miscellanea Analytica" and his contributions to the *Philosophical Transactions* of the Royal Society, for which in 1784 he was awarded the Copley Medal. Milner was both man of science and a divine, and became president of Queens' College, Cambridge, and Dean of Carlisle. Born in 1751, he was senior wrangler and Smith's prizeman in 1774, studied chemistry under Watson, and in 1783 became the first Jacksonian professor of natural philosophy. Resigning this post in 1792, "henceforth", it is said, "he gave up science in general except as an amusement". He had written works on motion, equations, the precession of the equinoxes, and natural philosophy, but after being appointed to the Lucasian chair on Waring's death in 1798, he contented himself with carrying out the minor duties of the post without doing any teaching.

It was while Milner held the chair that the writings and methods of the continental mathematicians began to be studied seriously at Cambridge, and with this came the reformation of mathematical studies not only in the University but also in the whole country. Foremost among the reformers was Robert Woodhouse (1773–1827), fellow of Caius College, who in 1803 published his "Principles of Analytical Calculations", and was chosen as Milner's successor in 1820. He held the chair for only two years, and within the next few years the chair was held by three different incumbents. From 1822 to 1826 it was occupied by Thomas Turton (1780–1864), a senior wrangler, who became professor of divinity, Bishop of Ely, and Dean of Westminster; during 1826–28 it was held by George Biddell Airy (1801–92), who vacated it to become Plumian professor of astronomy, a post he held until he was made Astronomer Royal; and in 1828 it was given to Charles Babbage (1792–1871).

With Herschel and Peacock, Babbage in 1813

had founded the Analytical Society at Cambridge, and in 1816 had translated Lacroix's "Traité élémentaire du calcul différentiel et du calcul intégral", thus ably furthering the movement begun by Woodhouse. It was the combined efforts of these four which paved the way for what has been called "the golden age of mathematics and physics at Cambridge". But, by 1828, Babbage was too deeply engrossed in his calculating machine to devote much time to the duties of a professor, and though he was sensible of the honour conferred upon him, "the only honour", he wrote, "I ever received in my own country", he contented himself with performing his duties as an examiner. As such he exerted considerable influence, and among the winners of Smith's prize examined by him was William Cavendish, afterwards Duke of Devonshire, chancellor of the University, and the founder of the Cavendish Laboratory.

Babbage held office for eleven years, when he was succeeded by Dr. Joshua King (1798-1857), who from 1832 until 1857 was president of Queens' College. By this time the new school of Cambridge mathematicians included many who were destined to become famous, and during the ten years Dr. King held the Lucasian chair, among the names of the senior wranglers and Smith's prize-winners were those of Ellis, Cayley, Adams, Todhunter, Kelvin, and Stokes, the last of whom in 1849, at the age of thirty, was chosen to succeed Dr. King. On the work of Sir George Gabriel Stokes (1819-1903), the immediate predecessor of Sir Joseph Larmor, it is unnecessary to dwell. During the fifty-four years of his tenure of the chair, he re-established the fame of the office once held by Barrow and Newton, and on the occasion of his scientific jubilee he was hailed as "the Newton of the nineteenth century".

Centenary of The British Medical Association *

THE British Medical Association, which is celebrating the centenary of its foundation at its annual meetings in London on July 21-29, is fortunate in having secured a chronicler worthy of the occasion in the person of Mr. Muirhead Little, who is not only a distinguished orthopædic surgeon but is also a well-known and accomplished writer on medical history. His work contains a very full and well-written description of the history of the British Medical Association and its multifarious activities during the last hundred years, together with an account of the leading personalities connected therewith.

Mr. Muirhead Little begins with a sketch of the medical profession in 1832, a year memorable not only for the foundation of the Provincial Medical and Surgical Association, as the British Medical Association was first called, but also for the first epidemic of Asiatic cholera in England, the Anatomy Act, and the First Reform Bill. In the absence of statistical information, the sciences of epidemiology and public health did not then exist, and indeed, until the passing of the Registration Act in 1836, there were no national statistics to justify any trustworthy conclusions. The profession as a whole was not organised, for there was no hard and fast line between the qualified and unqualified practitioner, and it was not until the Medical Act of 1858, which was almost entirely the work of the Association, that the great body of practitioners first received official recognition of their existence, and their importance to the State was acknowledged. The average medical practitioner in 1832 was a man of little culture or education, and there seems to have been ample justification for the unattractive picture of the contemporary medical student drawn by Dickens in "The Pickwick Papers" and by Thackeray in "Pendennis".

Dr. Charles Hastings, on the other hand, the founder of the Association, who was knighted in 1850, was a man of considerable abilities, some originality of mind, and great industry. At the early age of thirty-four years, he became the leading physician in Worcester, as well as being an eminent naturalist. In 1828 he founded the *Midland Medical and Surgical Reporter and Topographical and Statistical Journal*, which came to an end in 1832, being succeeded in 1840 by the *Provincial Medical and Surgical Journal*, the organ of the Association, which during the period 1832-40 had published only an annual volume of *Transactions*. It was not until 1856 that the Association, which had hitherto been known as the Provincial Medical and Surgical Association, received its present name, while its organ, which had been renamed the *Association Medical Journal* in 1853, was given its present title of the *British Medical Journal* at the beginning of 1857.

The scientific work of the Association, of which Mr. Muirhead Little gives a very full description, has formed an important part of its activities since its foundation. This work includes the discussion of scientific topics distributed over fourteen to twenty sections at its annual meetings; the dissemination of information in the *British Medical Journal* and the special journals, the *Archives of Disease in Childhood* and the *Journal of Neurology and Psychopathology*; the appointment from time to time of special committees to consider particular aspects of medical science; the arrangement of collective investigations throughout the profession; the award of scholarships, grants, and prizes; and the organisation of lectures, both among members of the profession and the lay public. Moreover, the local units, of which there are several hundreds, devote a great part of their energy to the consideration of scientific questions.

The work carried out by special scientific committees of the Association during the last fifty years includes reports on chloroform, the action of various drugs, the prevention of ophthalmia neonatorum,

* History of the British Medical Association, 1832-1932. Compiled by Ernest Muirhead Little. Pp. viii+342+29 plates. (London: British Medical Association, 1932.)

the early recognition of uterine cancer, the treatment of fractures, the question of rheumatic heart disease in childhood, maternity and child welfare work, tests for drunkenness, the causation of puerperal morbidity and mortality, psychoanalysis and mental deficiency. The subjects chosen for collective investigation have been chloroform, pneumonia, chorea, rheumatism, diphtheria, puerperal fever, the incidence of cancer and the history of its after-treatment.

As regards the work of the local units, it is noteworthy that whereas previously the formulation of a medico-political policy occupied most of their attention, of recent years they have devoted most of their energies to the consideration of scientific and clinical matters.

An important part in the scientific work of the Association is played by the library originally started by Mr. Ernest Hart, a former editor of the *British Medical Journal*, who made a nucleus collection of books from those sent him for review. Until fourteen years ago the library was available only for reference purposes, but since 1918 members have been allowed to borrow books and periodicals.

Although the account of the work of the Association in relation to medical reform, contract practice, and national health insurance may appear somewhat wearisome to the profane and even to some members of the profession not engaged in general practice, it should be borne in mind that it was mainly by the agency of the Association that not only the status and dignity of the profession in Great Britain were established, but also the interests of the general public were safeguarded.

Among other matters with which Mr. Muirhead Little deals are the work done by the Association on behalf of its members in the Services; its organisation of the profession in the War of 1914–18; its campaign against quackery, in which the publication of "Secret Remedies" and "More Secret Remedies" with their analyses of expensive but worthless nostrums was an important event; schemes of medical benevolence, and medical ethics. Short biographical sketches are included of some of those who devoted their energies to the growth and welfare of the Association, among the most notable being the two eminent surgeons, Sir Victor Horsley and Mr. Edmund Owen; the last two editors of the *British Medical Journal*, Mr. Ernest Hart and Sir Dawson Williams; Dr. Elizabeth Garrett Anderson, who took a large part in the admission of women to membership of the Association, and Prof. W. E. Dixon, the well-known pharmacologist, whose death we have recently had to deplore.

Mr. Muirhead Little has also included numerous excellent portraits of those who have deserved well of the Association during the last hundred years, including two of the founder, and views of the different buildings occupied by the Association in London and elsewhere. A list of the places of the annual meetings of the Association, with the names of the presidents and other principal officers, forms a useful appendix.

Obituary

Baron G. J. de Fejérváry

The death at Budapest of Baron de Fejérváry from heart-failure on June 2, after an operation for gall-stones on May 28, too early deprives zoological science of a worker rich in both accomplishment and promise, and his colleagues of a charming and helpful friend. He is mourned above all by a widow and two young children.

Geza Julius Fejérváry de Komlós-Keresztes was born at Budapest on June 25, 1894. On the completion of his university course, he entered the Hungarian National Museum in October 1916, and took up the study of reptiles and amphibians; in 1923 he was made curator of the herpetological section in the department of zoology, a post which he held until his death. Taking the degree of Ph.D. at Budapest in 1917, he became *privatdozent* for zoogeography at the R. Elizabeth University, Pécs, in 1921, and in February 1930 was appointed professor extraordinarius of zoology in that University. When the International Congress of Zoologists was held at Budapest in 1927, he served as recording secretary and afterwards edited its proceedings, tasks for which he was eminently fitted by his knowledge of the world, his courteous manners, and his facility in languages, which extended beyond the five world-tongues to Russian, Latin, and Greek. His own writings appeared in Hungarian, German, English, French, and Swiss publications.

While based naturally on his herpetological studies, Fejérváry's contributions to science, with their clearness and precision of statement, gave evidence of a wide philosophical outlook and a keen insight. He was interested in various problems of evolution and particularly in the question of its reversibility; thus in 1920 he published "Observations sur la loi de Dollo, . . ." (*Bull. Soc. Vaud. Sci. Nat.*); in 1924, "Remarks on Nopcsa's paper on Reversible and Irreversible Evolution" (*Arch. Naturgesch.*); in 1925, "Über Erscheinungen und Prinzipien der Reversibilität, . . ." (*Paläont. Z.*); also, in 1929, he criticised Sir Arthur Keith's presidential address to the British Association (*Biol. generalis*). Among the more important of his systematic and morphological papers were: "Contributions to a monograph on fossil Varanidæ and Megalanidæ" (*Ann. Mus. Nat. Hungar.*, **16**; 1918), "Die phyletische Bedeutung des Praehallux und vergleichend-osteologische Notizen über den Anuren-Tarsus" (*op. cit.*, **22**; 1925), ". . . on the primary and secondary dermal bones of the skull" (*Arch. Naturgesch.*, **90**, A; 1924).

In 1928, Fejérváry organised an expedition to Malta and the neighbouring islands to study questions of zoogeography; his report on this investigation was left incomplete, as also was an

extensive work on general zoology. It is to be hoped that some of the large mass of notes that remain may be in a state capable of publication.

BARON ERLAND NORDENSKIÖLD

WE regret to record the death of Baron Nils Erland Nordenskiöld, the Swedish ethnologist and explorer, which took place at Göteburg on July 5. Baron Erland Nordenskiöld, who was fifty-five years of age, was a member of a family already distinguished in the annals of exploration. He was the son of Baron Adolf Nordenskiöld, who discovered the North-East Passage, and a cousin of Prof. Otto Nordenskiöld, who led the Swedish Antarctic Expedition of 1902–3. He himself specialised in the investigation of the aboriginal cultures of America, and had travelled extensively among the native tribes, especially the less well-known, of both Central and South America, upon whom he had for long been recognised as the first authority.

The results of Nordenskiöld's investigations were embodied mainly in a series of "Comparative Ethnographic Studies", published in English, of which the first nine volumes, some in two parts, had appeared and others were in course of preparation. Of these, the most important was "The Copper and Bronze Ages in South America". Yet in dealing with the origin of American cultures and the problems of diffusion, the essential quality of his mind and its strict insistence on logical proof based upon a meticulous examination of the detailed evidence were best seen in his later publications, such as vols. 8 and 9 in the series, "Modifications of Indian Culture through Inventions and Loans" and "Origin of the Indian Civilizations of South America", the latter published in February last, in which he effectually vindicated the indigenous origin of certain important elements in Indian culture. He dealt with other aspects of the same problem in the Huxley Memorial Lecture delivered to the Royal Anthropological Institute in 1929, for which he received the Institute's Huxley Memorial Medal.

MR. G. H. HALLAM

THE death is announced of Mr. George Hanley Hallam, which took place at Tivoli on July 12. Mr. Hallam, who was in his eighty-sixth year, was a brilliant classical scholar. He was educated at Shrewsbury School and St. John's College, Cambridge, where he was bracketed Senior Classic in 1869, was Craven scholar, and won the Browne medals for a Greek ode twice and for a Latin ode. He was thereupon elected to a fellowship at St. John's College, and was appointed a master at Harrow in the following year. He retired in 1906.

Mr. Hallam had lived in Italy for many years and was keenly interested in the work of the British Schools of Archæology in Athens and in Rome, keeping in close touch with the latter through his friendship with the former director, the late Dr. Thomas Ashby, and the present director, Mr. Ian Richmond. He himself had a profound knowledge of the antiquities and topography of the Roman Campagna, and was a contributor to the *Journal of Roman Studies*. His most recent communication to that journal dealt with the tomb of a vestal virgin discovered at Tivoli in 1930; while another discovery, also at Tivoli, a fresco found in an underground tomb, was made the subject of interpretation in a contribution dealing with the cult of Hercules. Mr. Hallam's own residence at Tivoli was itself of considerable interest to archæologists, for it was a convent erected on the site of a Roman villa, reputed to be the actual villa which was a gift from Mæcenas to the poet Horace. On excavation, however, it proved to be more extensive than had been thought, and is now generally held to be the villa of Mæcenas himself.

Mr. Hallam's continued interest in Harrow and his belief in the educative value of a knowledge of Italian and Roman culture were recently shown by the foundation of an annual prize to enable an Harrovian to spend a few weeks in Italy.

MR. THOMAS BAT'A

THOMAS BAT'A, the distinguished and enlightened Czechoslovak manufacturer who met a tragic death in a flying disaster on July 12, just as he was leaving his aerodrome at Otrokovice in Moravia on a journey to Germany and England, was a leading Central European personality. From humble beginnings he built up one of the largest and most progressive leather goods concerns in the world. Through hard work, skill, and a thorough knowledge of all the details of the industry, he evolved the model establishment at Zlin, which has grown tenfold since the War, in order to accommodate his ever expanding undertakings. He was also responsible for the new educational buildings for the young and adult employees, and also for the up-to-date hospital and clinics which were at the disposal of townsfolk and others. Whilst he expected his workers to give their best service, he studied their interest in every way. He limited their duties to five days a week and encouraged them to improve their knowledge in their leisure, and anyone who showed ability or initiative obtained rapid promotion. He believed in strict discipline, but never expected anything from a worker that he was not prepared to accept himself.

Although Mr. Bat'a's energies seemed to be wholly devoted to industry, he found time for cultural pursuits and was an expert linguist. Czechoslovak educational and scientific institutes frequently received handsome donations from Mr Bat'a, and he provided funds for the excavations in Moravia which, a few years ago, revealed relics of a prehistoric settlement. Mr. Bat'a was fifty-six years of age.

News and Views

Jean Antoine Claude Chaptal, 1756–1832

WHEN on July 30, 1832—a century ago—Chaptal died at the age of seventy-six years, France lost a man of science and statesman who had, perhaps, done more to further the progress of the arts, industries, and manufactures of the country than any of his contemporaries. The son of a pharmacist, he was trained as a doctor, but it was chemistry which absorbed his attention, and it was as a chemical manufacturer that he first made a reputation. Born on June 4, 1756, at Nogaret, in the Department of Lozère, he graduated at Montpellier in 1777, and four years later was appointed to a newly founded chair of chemistry at the University there. With the fortune left by an uncle he established works for the manufacture of acids, alum, white-lead, and other commodities, and his success was such that in 1793 the Committee of Public Safety employed him with Berthollet and Monge to superintend the manufacture of munitions. Under Chaptal, the output of the Grenelle powder factory was raised to 1½ tons a day.

CHAPTAL became one of the first professors at the École Polytechnique, reorganised the Paris school of medicine, and after being made a Councillor of State, became Minister of the Interior. As such he energetically promoted trade schools, industrial exhibitions and chambers of commerce, and the construction of roads and improvements in public health. It was to Chaptal that Napoleon one day said, "I intend to make Paris the most beautiful capital in the world", and it was at Chaptal's suggestion that a canal was cut for bringing water to Paris from the River Ourcq. Though his loyalty to Napoleon afterwards led to his name being removed from the list of peers, he continued to work for the common good until loss of fortune and old age overtook him. Among his many books, that on chemistry applied to the arts, published in 1806, was translated into most of the languages of Europe, and long remained a valuable work of reference. His tomb is in the Père Lachaise, where so many eminent men of science are buried. He was a member of the Institut de France from 1816 onwards, and his *éloge* was delivered before the Academy of Sciences by Thenard.

Centenary of the British Medical Association

THE annual general meeting of the British Medical Association, which marks the official opening of the centenary meeting of the Association in London, will take place on July 23 at the Association's house in Tavistock Square, London. On July 24 a pilgrimage to Worcester has been arranged. In this city, in 1832, the project for an organised alliance of medical practitioners first took shape, under the guidance of Charles Hastings, who was born at Ludlow on Jan. 11, 1794. In the morning, Dr. W. G. Willoughby will unveil a plaque on a house in which Sir Charles Hastings formerly lived, the Mayor of Worcester assisting at the ceremony. An original portrait of Hastings (1839), by G. F. Faulkner, from the Board Room of the City Infirmary, will be handed over to the Association. From the house there will be a robed procession to the Cathedral to participate in a commemoration service, at which the sermon will be preached by Dr. E. W. Barnes, Bishop of Birmingham. A memorial window will be unveiled by the Right Hon. Lord Dawson of Penn. Lord Dawson will deliver his presidential address on July 26, at Queen's Hall, Langham Place, London, W.1. Next day the Lord Mayor and Corporation of London will hold a civic reception at Guildhall. A centenary dinner will take place at the Albert Hall, on July 28; Lord Dawson will preside and H.R.H. the Prince of Wales will be the principal guest. The clinical and scientific work of the meeting will be divided among twenty-four sections. In that devoted to the history of medicine (president, Dr. Charles Singer), in a discussion on various aspects of British medicine during the past hundred years, Sir Edward Sharpey-Schafer, the veteran physiologist, will open a discussion on the physiology of the period, while Dr. P. H. Manson-Bahr will open another dealing with tropical medicine. Personal letters and relics of British pioneers of tropical medicine will be shown by Dr. Manson-Bahr. A large number of Dominion and foreign guests is attending the centenary meeting.

Vienna Academy of Sciences

AT meetings of the Vienna Academy of Sciences held on May 30 and 31, Dr. Hans Molisch, emeritus professor of plant anatomy and physiology in the University of Vienna, was elected a vice-president, and Dr. Anton Eiselsberg, emeritus professor of surgery in the University of Vienna, was made an honorary member of the Academy. In addition to various Austrian members, the following foreign elections were made: Dr. Franz Kossmat, professor of geology in the University of Leipzig; Dr. E. B. Wilson, professor of biology at Columbia University; Dr. Michael Rostovtzeff, professor of ancient history and classical archæology at Yale University; Dr. Hugo Obermaier, professor of ancient history at the University of Madrid, and Dr. Norbert Krebs, professor of geography at the University of Berlin, to be corresponding foreign members; and Dr. Friedrich Meinecke, professor of history at the University of Berlin; Dr. Eduard Schwartz, professor of classical philology at the University of Munich, and Dr. Jakob Wackernagel, professor of classical philology at the University of Basle, to be honorary foreign members. The following awards of prizes were also announced: The Ignaz L. Lieben prize, jointly to Dr. Georg Koller for his work on the acids of lichens and Dr. Alois Zincke for his researches on perylene; the Haitinger prize to Dr. Otto Redlich for his investigations on the constitution of water and aqueous solutions; the Hansgirg prize to Dr. Hans Krumpholz for his determinations of the positions of double stars and comets; the Rudolf Wegscheider prize to Dr. Fritz Wessely for his work on glucosides, flavones, and natural coumarins;

and the Fritz Pregl prize to Dr. Moriz Niessner for his micro-analytical investigations on alloys.

Imperial Academy of Japan

AT a meeting of the Imperial Academy of Japan on May 10, annual medals and prizes were awarded to the following: Kyosuke Kindaichi for his studies on the Ainu epic "Yukar"; Kiyoo Wadati for his investigations on deep focus earthquakes; Ikutaro Hirai for his work on the cause of the meningitis-like disease frequently observed among Japanese suckling children; Tatuo Aida for genetical studies on the body colour of *Aplocheilus latipes*; Motojiro Matuyama for his geophysical investigations on gravity anomalies and magnetism of basaltic rocks; Shintaro Uda for research on ultra-short electro-magnetic waves. The Mendenhall Memorial Prize was awarded to Seishi Kikuchi for his studies on the diffraction of electron rays through thin mica plates.

Visceral Sense Organs

THE fourth Victor Horsley Memorial Lecture was delivered on July 20 in the Medical School of University College Hospital by Prof. E. D. Adrian, who discussed the "Visceral Sense Organs". The action of the sense organs in the lungs and in the great blood vessels can be studied by recording the nervous messages which they send to the brain stem, a method made possible by the use of valve amplification to magnify the electric changes in the sensory nerve fibres. The normal sensory discharges in the vagus and carotid sinus nerves were demonstrated by gramophone records in which the nerve impulses were converted into sounds varying in pitch with the frequency of the discharge. The sense organs in the lung resemble the muscle spindles, giving a rhythmic discharge of impulses so long as the tissues are stretched. In normal breathing the discharge only occurs at inspiration, but there are some endings which are excited by collapse of the lung, and these may be the cause of rapid breathing in pathological conditions. The sense organs in the aorta and sinus caroticus behave like those in the lung and give a faithful signal of the blood pressure. Both systems act as governors to keep the respiratory and vascular systems working within safe limits, and, as with all sense organs, their effect depends upon messages which are graded by changes in impulse frequency and in the number of units in action.

New Motor-Boat Record

ON July 18, Mr. Kaye Don, piloting Lord Wakefield's motor-boat *Miss England III*, twice broke the previous world's speed record for motor-boats. In his first attempt Mr. Don covered the measured mile in 35·4 sec. and 35·2 sec. (117·43 miles an hour), and in the second attempt his times were 34·4 sec. and 34·8 sec. (119·81 miles an hour). The previous record was set up by Mr. Garfield A. Wood, who achieved 111·71 miles an hour. Sir Henry Segrave's record on Lake Windermere when he was killed in 1930 was 98·96 miles an hour. *Miss England III* was designed and built by Messrs. John Thornycroft and Co., Ltd., at Hampton-on-Thames. It is a single-step vessel and is fitted with two propellers. The boat is fitted with two Schneider Trophy type supercharged Rolls-Royce engines, developing 2200 h.p. and consuming about five gallons of fuel a minute. The length of the hull of the boat is 35 ft., and the maximum beam is 9 ft. 6 in.

High Speed and Flight

A SERIES of comprehensive experiments upon the possibilities of high-speed flight has been carried out in the Langley Field High Speed Wind Tunnel of the National Advisory Committee for Aeronautics in the U.S.A. Air speeds up to 800 miles an hour, which is faster than the speed of sound, have been reached. It has been definitely established that with the present conventional form of wing section there is so great an increase in drag at about 600 miles an hour that it will be impossible to carry sufficient power to overcome it, assuming the present methods of conversion of fuel to air thrust. This is confirmed by experience with high-speed propellers, the blade tips of which may easily be travelling at a peripheral speed approaching the velocity of sound. In such cases their outer portions may be actually exerting a negative effect. The delicate mechanisms of the human body do not appear to be susceptible to steady high speeds, but they react to accelerations at much lower figures. This case arises often during flight, when every turn is an angular acceleration. It has been established that the maximum speed that the human body can stand during an average sharp turn is about 300 miles per hour. The present speed record for flight in a straight line is an average 408·8 miles an hour, although speeds up to 415·2 miles an hour for short periods have been recorded.

Constitutional Tendencies in the Orient

AT a time when a bold experiment in the method of governing India is to be made and the details of the new federal constitution are being elaborated, a thoughtful paper by Sir Arnold Wilson, in the *English Review* for May, on the relative merits of government by means of an executive responsible to an elected body and by bureaucratic methods, should be read. As is well known, the application of the democratic principle to Eastern conditions is by no means new. It has already been attempted, not only in the management of local affairs in India itself, but also in a wider field in other countries, such as Turkey, Egypt, Persia, Iraq, Cyprus, Ceylon, and the Dutch East Indies. The results so far obtained are described in detail in the paper under review. They make very melancholy reading. In these very different localities, the introduction of the electoral principle has almost without exception either ended in complete failure or has been disappointing. On the other hand, in the overseas possessions of France and Italy, where the system adopted is a benevolent autocracy, the people are said to be contented and there is little or no unrest of the type now so common throughout India.

The Indian Problem

IT is difficult to resist the conclusion that had the Indian problem been approached at the very outset by the methods familiar to the man of science, one of

the first tasks would have been a careful study of the literature of the subject and particularly of the results already obtained from the experiments in the art of ruling which have been made in other countries. This procedure, however, does not appear to have been followed. Even the Commission which recently worked under the able guidance of Sir John Simon was not empowered to study constitutional developments in other Asiatic countries, otherwise " they might well have hesitated before recommending even a moderate extension of the franchise". The matter, however, has gone too far for such studies to be undertaken. The new constitution will shortly be established: the results will soon be clear to all. If it succeeds, all criticism will be laid to rest by the one unanswerable argument—success. If it fails, a new Indian Civil Service, in which it is hoped that science will take its proper place, will have to be re-established.

A High-Efficiency Gaseous Lamp

Messrs. Philips Lamps, Ltd., are introducing a new lamp which has an efficiency of about eight times that of a gas-filled lamp taking the same power. A description of the lamp is given in the *Electrical Times* for July 14. In the new lamp an electric discharge passes through a rare gas ' filling ' with a small quantity of metallic sodium. There is an oxide cathode with one or two anodes. The bulb of the lamp is in the shape of a cylinder, which has to be heated up to a certain temperature sufficient to vaporise the sodium. The lamp is enclosed in a second cylinder, which accelerates the heating and keeps the temperature constant. The discharge and consequently the emission of light depend mainly on the sodium vapour. The colour of the light is yellow and practically monochromatic. This colour is favourable to good visibility and therefore the lamp is very suitable for street lighting. A photograph taken at night is shown of a long length of road in Holland illuminated by the new gaseous lamps. It has been noticed that drivers of fast cars when entering the newly lighted part of the road switched off their headlights unasked. Hence there is no ' dazzle ', the elimination of which is one of the greatest problems of night driving. The candle-power of the lamps is 500-600 for the smallest size made, which take 100 watts. These lamps will be useful where colour is of minor importance. For domestic use a whiter light is more desirable.

Modern Developments in Precision Clocks

The most accurate timekeepers of to-day are divided into two classes, depending on whether the restoring force of the oscillator is gravity, as in pendulum clocks, or elasticity, as in quartz crystal oscillators. In a monograph by A. L. Loomis and W. A. Marrison on precision clocks, published in the *Transactions of the American Institute of Electrical Engineers*, an account is given of the performance of a set of 100,000-cycle quartz oscillators built by the Bell Telephone Laboratories for use as a primary frequency standard. The frequency of quartz oscillators is practically independent of the amplitude. They are not affected by gravity or magnetic fields and can be easily shielded from electrostatic fields. They are practically unaffected by heavy traffic in neighbouring roads or by the vibrations near earthquake zones. A crystal clock standard is more costly than a pendulum clock of the highest precision, but it can be used for many purposes. For example, an absolute comparison of crystal clocks can be made with an error of less than one hundred-thousandth part of a second, and can be maintained continuously. For short time comparisons an inaccuracy not greater than 1 in 10^{10} has been obtained. The high accuracy of comparison is due chiefly to the fact that the number of vibrations is 200,000 times greater than with a ' seconds ' pendulum. A comparison made of the data obtained by observing the difference in the rates of a crystal clock and three pendulum clocks revealed for the first time a lunar day variation. This is due to the fact that the crystal does not respond to variations in the gravitational effect of the moon, while the pendulum does. The difference in the rates of the clock and the crystal timekeeper thus contains a term depending on the period of the lunar day.

Jubilee of the Ferranti Works

The late Dr. S. Z. de Ferranti at the age of eighteen was the principal founder of the original company of Ferranti, Thomson and Ince in Charterhouse Square, London, in 1882. It is a little difficult to realise that there was then a great demand for electric meters. Messrs. Ferranti, Ltd., now of Hollinwood, Manchester, held an exhibition at Bush House, London, during June to commemorate their jubilee. The fifty years' life-story of the firm shown by the historical exhibits is largely a history of the development of public electricity supply. A particularly interesting exhibit was the earliest models of Ferranti meters, some of which have only recently been taken out of service. The new methods of hardening the pivots and burnishing them so as to get the exact shape with the help of a micrometer jewel examiner with a powerful microscope were shown in action. New devices rendered necessary by the 132-kilovolt grid scheme in Great Britain were shown in action. An even more recent development is the manufacture of electric clocks, which are now made quite cheaply, of all sizes and shapes with cases of bakelite, wood, or metal. A prominent feature of the radio exhibit was a new seven-valve receiving set. A full range of water heaters and fires were shown. A working model of the Ferranti hot-water system for a house employing those heaters was shown. The ' Era ' fire which Ferranti's make is said to be ideal for devices for hatching chickens (chicken brooders). The machines used at the Ferranti works in Hollinwood are of the most modern design, and employ more than five thousand workmen.

Tuberculosis in England and Wales

The Report on Tuberculosis by Dr. A. S. MacNalty to the Ministry of Health (Reps. on Pub. Health and Med. Subjects, No. 64. H.M. Stationery Office. 3*s*. net.) may be regarded as an ' audit ' of the present position of the tuberculosis question in Great Britain. Tuberculosis is a disease not only of medical interest but also of wide sociological and economic importance. Anti-tuberculosis measures cost the country a great deal; for example, some 2½ million

pounds are expended annually on the maintenance of residential institutions for treatment. During twenty years of anti-tuberculosis campaign, the decline in the mortality from the disease has been striking—from a total of 53,120 deaths in 1911 to 35,745 in 1930. One of the most interesting and important sections of this Report deals with the results of sanatorium treatment. This is very difficult to evaluate, for the ultimate result depends so much on a variety of factors, such as (1) the type of the disease—some cases progress to a fatal issue in spite of all treatment, (2) the social position and sex of the patients, (3) the stage of the disease when treatment is commenced, (4) the age of the patients—pulmonary tuberculosis in the young adult tends to shorten life much more markedly than when it occurs in or after middle life, (5) the circumstances of the patient after discharge—the character of his home surroundings, his own care of his health, the nature of his occupation, and the like. It is concluded that some fifty-seven per cent of male and sixty-seven per cent of female patients in the second stage of pulmonary tuberculosis survive, often with good working capacity, for five years or more; a result which fully justifies the provision of sanatorium treatment. Much important information is embodied in this Report upon such subjects as after-care and village settlements for the tuberculous, methods of diagnosis, and special forms of medical and surgical treatment.

Science in the 'Sixties

A pamphlet with this title by Sir Oliver Lodge forms one of a series edited by Mr. John Drinkwater and addressed to men of letters. In it Sir Oliver contrasts the indifference displayed by the public and the Press to scientific discoveries made in the 'sixties with the universal interest shown at the present time in such subjects as relativity and the constitution of the stars. For the science of the 'sixties, Sir Oliver confines himself almost entirely to the theory of the electromagnetic field brought forward by Maxwell as the mathematical interpretation of Faraday's lines of force. He uses the words 'juggled with' to describe the process by which Maxwell evolved the electromagnetic theory of light from his mathematical expressions. This seems to us an unfortunate choice of words, likely to produce a wrong impression on the minds of readers. The steady progress from Maxwell to present-day wireless is outlined, and Sir Oliver concludes by giving his opinions on current theories. The new doctrine of uncertainty he summarises in "the act of *observing* carries with it inevitably an act of *perturbing*", but he denies that this renders events unpredictable. By 'faith' only does he accept relativity, but wave mechanics "is a healthy infant of great promise".

Scientific Apparatus of Historical Importance

SEVERAL daily newspapers recently published a letter from the Institute of Physics over the signatures of Lord Rutherford and others asking for the co-operation of anyone possessing pieces of apparatus likely to be of historical importance. In 1925 the Institute of Physics appointed a committee to advise on the preservation of such apparatus. This committee is anxious to trace any pieces with which fundamental research in physical science has been carried out, and to arrange for their preservation. The committee has also entered upon the task of drawing up a catalogue of such pieces. Several pieces of great historical importance have already been secured for the nation and are now housed in the Science Museum at South Kensington, and the response to the recent letter has brought to light several other important pieces. Articles describing and cataloguing such pieces are published from time to time in the *Journal of Scientific Instruments*. Many readers of NATURE may have such apparatus in their possession or under their charge; and the Secretary of the Institute of Physics, 1 Lowther Gardens, Exhibition Road, London, S.W.7, will be grateful for any information that will assist in tracing such pieces or in completing the catalogue. For the benefit of future historians of physical science it is desirable to have as complete a record as is possible of the work of British physicists, and it is to this end that this task has been undertaken.

Cremation and Population

MRS. ALEC-TWEEDIE'S address on "Cremation the World Over" at the Cremation Conference, which was held at Brighton on July 18-21, reinforced a strong appeal for the wider adoption of this method of disposal of the dead by reference to the distribution of the custom of burning the dead among peoples of antiquity and non-European races. She dwelt in particular on the practice of cremation among the Hindus, contrasting it in detail with the methods of burial among the Chinese, and pointing out how among the latter reverence for the last resting-places of the dead, where land enclosing burial mounds is under cultivation, hampers agriculture and is an increasing menace to food supply among a teeming population which already produces barely enough for its needs. The vastness of the population, it might be added, makes the practice increasingly detrimental from the point of view of hygiene. Although Mrs. Tweedie did not hesitate to make use of the appeal to the emotion which reflection on the conditions and consequences of inhumation never fails to arouse, a marked feature of her address was the emphasis with which she stressed the import of cremation as a factor in the world's population problem, linking it up with food supply and birth control in relation to over-population. As she put it in her closing words, "Without birth control and world cremation, what will the end be?" Mrs. Alec-Tweedie was the first and only woman on the council of the Cremation Society of England for more than ten years. She is the daughter of the late Dr. George Harley, F.R.S., of Harley Street, and her brother was Dr. Vaughan Harley. Her brother-in-law is Dr. Francis Goodbody, who has done much work for the centenary meeting of the British Medical Association.

Population of London

THE volume of the Census, 1931, which covers the County of London has been published (London: H.M. Stationery Office, 3s. net). The total population enumerated in the City of London and the twenty-

eight Metropolitan Boroughs comprising the Administrative County of London on the night of April 26/27, 1931, numbered 4,397,003 persons. The males and females were respectively 2,044,108 and 2,352,895, a ratio of 1151 females per 1000 males. For the third decennium in succession, the County population shows a decline, the loss during the past ntercensal period being 87,520, a number comparable with the population of a good-sized town like Ipswich or Wigan. The number of private families has increased by 6·17 per cent, and the average size of the family has been reduced by 8·7 per cent, to 3·46 persons. With the reduction in the average size of the family, the average number of persons for each occupied room has declined from 1·05 in 1921 to 0·98 in 1931; that is to say, on an average there is less overcrowding. In Greater London, which occupies roughly a circle of 15 miles radius with Charing Cross as a centre, 8,203,942 persons were enumerated, or more than one-fifth of the total population of England and Wales.

Forecasting Mortality

IN a lecture to the Norwegian Actuarial Society printed in the *Skandinavisk Aktuarietidskrift*, Mr. Palin Elderton takes up the fascinating subject of forecasting mortality. Most medical statisticians and actuaries, if only for their private amusement, have tried their hands at prophecy. The most obvious line of approach, when rates of mortality in age groups are available over a long series of calendar years, is to take each group separately and to study the form of secular change, then, having more or less successfully represented the trend by some mathematical function, to extrapolate horizontally. As Mr. Elderton points out, this method would be inappropriate if changes in mortality at a later age are really determined by the experience through which the generation of which those at the later age are survivors have passed. In that case, one should consider not the horizontal but the diagonal progression of the table.

Prehistoric Chronology

AT the request of the editor of *Antiquity*, Mr. Miles C. Burkitt and Prof. V. Gordon Childe have prepared a chronological table of prehistory, which is published in the June number of that periodical. The progress of recent research in prehistory will secure a welcome for the chart among students, not least perhaps because of the decisive manner necessitated by its form in dealing with controversial points, which should at least be provocative of fruitful discussion. The compilers have found that a task which they anticipated would give rise to no great difficulty has proved of no little complexity. Failing the ideal method of distribution maps, it was found most practical to divide the map into several geographical areas, each of which heads a column in the list. Even so, the area of extent of specific cultures has sometimes been difficult to determine and represent. It has been found impracticable to give an absolute chronology much before 2000 B.C. In glacial chronology most of the Mousterian is taken as contemporary with Würm ii, Acheulean with Riss-Würm, and Chellean with Mindel-Riss, while pre-Chellean is definitely pre-Mindel. Even when allowance is made for local specialisation and retardation, and when a solar chronology becomes possible with the dated monuments of Egypt and Mesopotamia, difficulties have still to be overcome, as witness the correlations here put forward between Egypt and Mesopotamia, which, it is admitted, are not universally accepted. The chronological chart, with explanatory notes on each section and index, has been reprinted and is obtainable separately, price 2*s.* 6*d.*, from the assistant editor of *Antiquity*, 24 Parkend Road, Gloucester.

Re-opening of the South African Museum

ON June 1 the Governor-General of the Union of South Africa, the Earl of Clarendon, opened the reconstructed South African Museum in Cape Town, and so marked the accomplishment of an instalment of the development scheme of the trustees. The Museum, founded as a Cape Government institution in 1885, was housed in a new building in 1897, but had seriously outgrown the accommodation there. The present additions permit of a running sequence in the exhibits of different sections, and have given new opportunities for the proper display of some of the treasures the Museum possesses. The additions, on two stories, consist of the old Art Gallery and an entirely new block on the opposite or Avenue side, forming two large halls, 90 feet long by about 35 feet wide. The lower of these is devoted to ethnology, and here the famous life-casts of native races have found a fitting place; the upper contains the big-game collection, and the opening is marked by the addition of a new group of springbok. The trustees and Dr. Leonard Gill have made a notable contribution to museum progress in the Union.

Albinism in Wild Animals

A VERY interesting specimen recently received at the London Zoological Gardens is a young albino reticulated python. Its eyes are pink, but the usual markings are present in orange-colour on the white skin. Albinism seems to be very rare in cold-blooded animals, but a few years ago the Gardens exhibited an albino cobra, and many years before that an albino common frog. The albino form of the axolotl, of which specimens can be seen in the aquarium, is bred in domestication like the ordinary black form, but all such specimens appear to have descended from one albino which came in the first consignment of live axolotls received in Europe during the last century. Albino or 'silver' goldfish are well known, and in the Zoological Society's aquarium can be seen white as well as golden specimens of common carp; but these, again, are domesticated. Neither white axolotls, white goldfish, nor white carp have pink eyes, and so fall short of complete albinism. It has been noticed in birds that an albino or lutino specimen, if pink-eyed, retains its abnormal hue, but if normal-eyed, is liable to revert to type on moulting.

Modifying Broadcasting Voices

IN a broadcast talk given in America by O. H. Caldwell, the editor of *Electronics*, a method of improving the voices of some of the political speakers was described. By using a suitable combination of

electrical devices in connexion with the microphone, it is possible to improve the broadcast voice by smoothing out rough and strengthening weak notes. Sounds sent over the radio can be varied by placing in the broadcasting circuit filters, compensators, and amplifiers so that the frequency and volume are permanently varied or are left to be varied at the discretion of the control engineer. High-pitched voices are transmitted much better than deep voices over the radio. It was suggested that by putting different compensators in various branches of the broadcasting networks it would be possible for a political candidate to talk with the appropriate accent in several States simultaneously.

Standardisation at the Ottawa Conference

THE question of industrial standardisation will again come before the Imperial Conference when it meets in Ottawa at the end of this month, and Mr. C. le Maistre, director of the British Standards Institution, has been appointed adviser to the delegation from Great Britain on British standards. It will be recalled that at the last two Imperial Conferences very great importance was attached to the development of inter-Empire standardisation, and to the preparation of national industrial specifications by national standardising bodies. In order to fulfil the recommendation of the last Imperial Conference, the British Engineering Standards Association recently widened its scope, and is now known as the British Standards Institution. Since last November, Mr. le Maistre has been touring the Dominions in connexion with the development of this work.

New Deposits of Tin in the U.S.S.R.

THE expedition of the Soviet Academy of Science under the direction of Dr. A. E. Fersman has discovered new deposits of tinstone in Tadjikistan, to the north-east of Stalinabad. The Soviet Union so far has not had its own supply of tin ore, the working of the two deposits in Transbaikalia having only just commenced. The discovery of new rich deposits of tinstone is of great importance to the national economy of the U.S.S.R., particularly in the manufacture of tins for preserved foods, in the motor tractor industry, in the production of steam engines, etc.

Announcements

THE REV. J. P. ROWLAND, *S.J.*, has been appointed director of the Stonyhurst College Observatory, in succession to the Rev. E. D. O'Connor, *S.J.*, who has been appointed rector of the College.

AT the quarterly meeting of the Royal College of Surgeons held on July 14, Sir H. J. Waring was elected president of the College in succession to Lord Moynihan. The Lister Memorial lecture of the College will be delivered by Sir Charles Ballance on April 5, 1933.

THE following officers have been elected to the Council of the Institution of Electrical Engineers for the year 1932–33, to take office on Sept. 30:—*President*, Prof. E. W. Marchant; *Vice-President*, Mr. H. T. Young; *Hon. Treasurer*, Mr. P. Rosling; *Ordinary Members of Council*, Prof. J. K. Catterson-Smith, Mr. A. P. M. Fleming, Mr. H. W. H. Richards, and Mr. W. S. Burge.

AT the annual general meeting of the British Association of Research for the Cocoa, Chocolate, Sugar Confectionery, and Jam Trades, which was held on July 5, Mr. J. G. Mathieson was re-elected president and Mr. A. W. Beach and Mr. C. E. Southwell were re-elected vice-presidents.

IT is announced that by the will of Mr. James M. G. Prophit, a sum of about £120,000 is to be divided equally for the purposes of cancer and tuberculosis research. The tuberculosis moiety has been allocated to various hospitals and colleges, including the Royal College of Physicians, and to two studentships. The cancer moiety has been allocated chiefly to the Royal College of Surgeons, the Radium Institute, the British Empire Cancer Campaign, and also to two studentships.

THE ninth Annual Conference of the Association of Special Libraries and Information Bureaux will be held at Somerville College, Oxford, on Sept. 23–26. The presidential address will be delivered by Sir Charles Sherrington on Sept. 23. Among the papers to be read at the Conference are: "The Relationship between Science and the Humanities", by Prof. J. L. Myers; "Classified Subject Indexes to Periodical Volumes", by Dr. S. C. Bradford and Prof. A. F. C. Pollard; and "History and Sources of Official Vital Statistics", by Prof. M. Greenwood. Particulars of the Conference can be obtained from the General Secretary, Association of Special Libraries and Information Bureaux, 16 Russell Square, London, W.C.1.

MESSRS. W. Heffer and Sons, Ltd., have issued a catalogue (No. 390) of publishers' 'overstocks', or 'remainders' as they are more generally termed. All books are new and are offered at about half the published price or less. We notice in the section of reference books sets of Millais' "Mammals of Great Britain and Ireland" and Thorburn's "British Mammals".

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A part-time lecturer in the Biology Department at the Plymouth and Devonport Technical College—The Secretary for Education, Education Offices, Rowe Street, Plymouth (July 23). A lecturer in mathematics at the Portsmouth Municipal College—The Registrar (July 29). A resident engineer in the Public Works Department, Hydro-Electric Branch, of the Government of the Punjab—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (Aug. 4). An assistant teacher of mechanical engineering and an assistant teacher in the Nautical College at the Central Technical School, Byrom Street, Liverpool—The Director of Education, 14 Sir Thomas Street, Liverpool (Aug. 8). A full-time secretary to the Museums Association—The Secretary, Museums Association, 39B Alfred Place, South Kensington, London (Aug. 10). A junior assistant in the Directorate of Ballistics Research, Research Department, Woolwich, S.E.18.—The Chief Superintendent. A physics laboratory assistant at the Radium Therapy Department, Duke of York Home, Bradford.

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Inheritance of Acquired Characters

IN making my final reply to Prof. Haldane, whose letter appeared in NATURE of July 2, I am actuated mainly by two motives, namely: (1) to try to dispel the mist of mental confusion in which Prof. Haldane is enveloped with regard to 'selection', and (2) to prove to readers of NATURE the baselessness of Prof. Haldane's attempts to discredit the evidence for the inheritance of habit given in my Royal Institution discourse.

I think that my first object can best be attained by referring to a somewhat similar controversy which I conducted some years ago with Prof. Julian Huxley, for whom, as a zoologist, I have a great respect, although I differ widely from some of his conclusions. I then stated the case for the inheritance of habit somewhat as follows: the ordinary routine experiment practised by Mendelians of crossing the races of domestic animals, such as mice and guinea-pigs, is one which requires no particular skill to carry out. If continued to all eternity it would throw no light whatever on the inheritance of habit: to test this, a special form of experiment is necessary, infinitely more difficult to carry out than the Mendelian one and requiring far more time for its execution. We must discover a species of animal sufficiently plastic in its constitution to respond within the period of its lifetime to a change in environment by some observable change in structure or behaviour: we must then breed from the altered individuals and examine whether some trace of the alteration is transmitted to the next generation, in spite of the fact that this generation has been returned to the typical environment. But Prof. Haldane objects that if we do this we are 'selecting'; yet what else can we do? The question at issue is whether an acquired habit is inherited. How can we test this except by breeding from animals which have acquired the habit? Perhaps Prof. Haldane means that not all of the individuals exposed to the new environment respond equally to it, and that those which do respond owe their power to something queer 'turning up' by accident in their constitution. It is in general true that whenever we expose animals to any set of new conditions we do not get a uniform response on the part of all, but a series of responses graded in intensity. This has been noticed by all workers in this field. Long ago Kammerer observed that only his most vigorous salamanders responded adequately to the colour of the background. This variation in response, however, is not due to mysterious 'genes' turning up, but solely to differences in vigour.

Coming now to my second object, I maintain that Prof. Haldane's assertion that all that Dürken obtained was gained by the selection of a race of green pupæ from a mixed population is without foundation. The 'green pupæ' are merely the end terms in a graded series of pigment reduction which occurs as a reaction to orange light, and the population is not mixed. The critical question is whether this reaction affects the reactions of their descendants—and this Dürken has proved up to the hilt. From 33 to 50 per cent of the next generation retain the lack of pigment in spite of an exposure to ordinary daylight. As I mentioned in my previous letter, Dürken in one of his later experiments obtained practically a 100 per cent response from a population exposed to an orange light, but this is rare. To all those, however, who wish to follow up this subject further, I recommend a perusal of the relevant passages in Dürken's book, "Grundriss der Entwicklungsmechanik". They will there find the questions of 'mixed populations' and 'selection' considered and decided in the negative, and they will be in a position to judge of the exact value of Prof. Haldane's statements.

We now come to the experiments of Metalnikoff. In my Royal Institution discourse I quoted from a review of Metalnikoff's work in a French scientific journal. Since then, however, we have taken up seriously the question of repeating Metalnikoff's experiments in my laboratory: we have obtained all Metalnikoff's publications, including the book in which he describes his experiments not only with the cholera bacillus but also with a number of other bacilli, and there is not a shadow of a doubt that Metalnikoff did not breed from the survivors of the individuals inoculated with the bacillus but from those immunised with the vaccine. Refreshing my memory the other day, I find that in one culture in the tenth generation of immunised insects 77 per cent of the individuals inoculated with the bacillus survived.

Here I should like to put on record my deep feelings of gratitude to Dr. Ledingham and his colleagues of the Lister Institute who have helped us by supplying standardised cultures of bacilli every time we wish to make an experiment. So far as I could discover, Dr. Ledingham and his colleagues were the only people in London who knew of and appreciated Metalnikoff's work. Whether we shall succeed in obtaining the same results as Metalnikoff remains to be seen.

I now come to Prof. Haldane's comments upon Prof. Heslop Harrison's experiments with the sawfly *Pontania salicis*. He suggested in his discourse that Harrison's strain of sawflies had become contaminated with a strain adapted to the new willow: that these individuals survived, and that so a false appearance of the artificial production of a new habit was created. To this I replied that the "new willow" was a rare hybrid; and that the idea of the sawflies becoming contaminated with a strain adapted to this willow was mere hypothesis. It must have been obvious to all readers that I had obtained these facts from Prof. Harrison, but in his letter Prof. Haldane directly challenges them, which seems a rash proceeding, considering that Prof. Harrison occupies a chair of botany and is unrivalled for his knowledge of the systematics and ecology of the British flora. Prof. Haldane asserts that the so-called rare hybrid is economically important and is cultivated in 69 vice-counties, whereas the unimportant original host-plant only grew in 34 vice-counties. I referred the matter to Prof. Harrison, and received from him a reply which disposes completely of Prof. Haldane's objections.

As I gave a list of eminent authorities who had become converted to Lamarckism, Prof. Haldane quotes against me the Royal Society motto, "Nullius in verba". As I am a fellow of that Society of twenty-seven years' standing, this was a superfluous attention on the part of Prof. Haldane. Of course, I accept it. Opinions *qua* opinions prove nothing, but this is not a fair way of stating the case. In a subject of the vast extent of zoology, the life-long efforts of one investigator can only enable him to cultivate *in detail* one limited part of the field, and yet it is precisely on this *detailed* study that the solution of all the major problems of the science depend. In my discourse I referred to three types of such detailed studies, namely, systematics, embryology, and palæontology. Nineteenth century morphology was only suggestive, not

demonstrative, because the comparisons on which it rested were of too sketchy and remote a character and the gaps bridged by hypothesis were too wide, and so morphology was led in many cases to wild and ridiculous conclusions. But the opinion of an expert in systematics is not to be dismissed as mere "verba". It is really a deduction from thousands of relevant facts which the critic has neither the time nor experience to be able to consider.

Prof. Haldane concludes with a disquisition on the subject of mutations, into which I will not follow him. As I said in my previous letter, it would have been an easy matter to have gone over the whole of his discourse and applied destructive criticism to every part of it, but I determined to confine myself to meeting his objections to the evidence adduced by me. But I shall conclude by placing on record my view of the nature of mutations and trusting to the future to vindicate it.

Johannsen, who invented the term 'gene', later publicly expressed his regret that he had ever done so, and defined mutations (or genes) as "superficial disturbances of the chromosomes". They have nothing to do with the characters of the natural races of animals (or plants). With this opinion I fully agree. Mutations begin differently and are inherited differently from true racial characters. This is the opinion of the best systematists whom I know, and surely in the long run the opinion of those who really understand what species, sub-species, and biological races are will ultimately prevail.

E. W. MACBRIDE.

43 Elm Park Gardens,
Chelsea, S.W.10,
July 2.

PROF. J. B. S. HALDANE, in his reply (NATURE, July 2) to Prof. E. W. MacBride's letter, once more returns to the subject of my experiments with the sawfly *Pontania salicis* and its transference from the foodplant *Salix Andersoniana* to *S. rubra*. As this portion of his letter is misleading, and might appear convincing to anyone not acquainted with the facts, it seems that a statement from me is necessary.

Actually, owing to Prof. Haldane's lack of knowledge of the geographical distribution of the two willows in question, not one of his remarks is relevant to the subject. It still remains a fact that *S. rubra* is a rare hybrid between *S. purpurea* and *S. viminalis*, and to challenge this on the ground that Druce records it from sixty-nine vice-counties shows a lack of appreciation of the basis of such a list, and of the numbers of individuals which represent such a hybrid in Nature. Moreover, the introduction of a reference to the value of *S. rubra* as an osier only makes matters worse; osiers are not cultivated here.

Again, when Prof. Haldane quotes Druce as recording *Salix Andersoniana* from thirty-four vice-counties, scientific accuracy should have caused him to state that these thirty-four (except for an outlier in Glamorgan) lie north of a line drawn across the country from N.E. Yorks to Lancashire. The probability of *S. Andersoniana* coming into contact with osier beds is thus very remote. Further, his statements imply that he does not realise that, in those northern and Scottish counties where both plants occur, the favoured habitats of *S. Andersoniana* differ widely from those of *S. viminalis*, *S. purpurea*, and, consequently, of their hybrid. In Durham, for example, *S. Andersoniana* is a plant which grows in profusion on the sea banks on the magnesian limestone and then jumps to subalpine areas well inland, whilst *S. viminalis*, *S. purpurea*, and *S. rubra* occupy the intervening zone. Very rarely indeed do *S. Andersoniana* and *S. rubra* overlap; in fact, in spite of very careful exploration to settle this very point, I cannot point to one locality which they possess in common!

Prof. Haldane ought to have realised that before I commenced the experiments I should take the elementary precautions of making sure (1) that the small patch of *S. rubra* selected for the work was free from *Pontania* galls, (2) that no other species of willows near carried the same species, and (3) that the colony of *S. Andersoniana* from which the transference was made was in a district remote from contact with *S. rubra*.

Filtration of Plant Viruses

THE preparation of graded collodion membranes has been greatly improved of recent years by W. J. Elford, who has developed a technique with which he can produce membranes of highly uniform structure and easily determinable average pore size. These he has used in an investigation of the probable sizes of bacteriophage and various animal viruses. We have examined a number of plant viruses with membranes prepared according to Elford's methods and with his generous help and advice; and a short statement of some of our experiences and results may be of interest in themselves and of value to others.

First as to the method of preparation of the membranes. In our hands it has not proved easy to obtain consistent results. The eventual pore size is dependent on the rate of evaporation from the surface of the liquid and is also enormously affected by the presence of traces of water; and very small local or general differences in atmospheric humidity, slight currents of air, and the like affect the final product to a surprising extent. There may be marked difference of pore size between the central area of a membrane and the portions lying nearer the rim. Such difficulties are not insuperable, but the most painstaking attention to detail is essential, and at present we find it advisable to standardise every membrane individually before use. Standardisation leaves room for some degree of latitude in the data, and, leaving aside theoretical considerations as to the applicability of the formula used to membranes of this structure, in our hands repeated standardisation of the same individual membrane has shown a progressive diminution in average pore size. These difficulties are gradually disappearing, but we mention them as a warning of the necessity of checking one's results with the greatest care.

The virus material we have used consists of juice extracted from diseased plants. This juice is very complex and may contain tannins, resins, and other readily precipitated materials which do not occur in animal tissues. As a consequence there is a rapid clogging of the pores, especially of the finer membranes, in spite of very thorough preliminary clarification by passage first through paper pulp and then through a coarse ($0{\cdot}6\mu$ or $0{\cdot}7\mu$) membrane. With some plants, for example, tomatoes, especially if more than a very few weeks old, this plugging is so thorough as to make the results quite useless as a guide to the size of the particles. With tobacco and certain other plants it is much less serious, but it is always present to some extent. To this is perhaps to be attributed the fact that we do not get a sharp endpoint. We do not find that the virus passes undiminished in quantity through the series of membranes down to a definite pore size, at which it no longer passes; there is a progressive reduction in amount all the way down. To take one example (where the quantity of virus

present was estimated by the number of spots developing on the leaves of *N. glutinosa*), after passage of paper pulp the number of spots was 407 per leaf; after $0{\cdot}8\mu$ membrane, the number was 220; after $0{\cdot}49\mu$, 38; after $0{\cdot}25\mu$ it was 6, and after $0{\cdot}1\mu$ or less, there were no spots. It may be necessary to remove this clogging material before passage of the membranes, and experiments are in progress for this purpose.

With all qualifications made, the results obtained are of interest and significance. As is the case with animal viruses, we find that the plant viruses differ greatly in size among themselves. The virus of tobacco mosaic (Johnson No. 1) passes the $0{\cdot}51\mu$ membrane, though in reduced quantity (only 4 plants infected out of 8), and passes the $0{\cdot}154\mu$ easily. The virus of yellow tobacco mosaic (Johnson No. 6) is of the same size, passing $0{\cdot}051\mu$ (2 plants positive of 8). Aucuba mosaic virus passes $0{\cdot}120\mu$ and $0{\cdot}112\mu$ but does not pass $0{\cdot}10\mu$, $0{\cdot}06\mu$, or $0{\cdot}051\mu$. The virus of a *Hyoscyamus* disease found by Dr. Marion Hamilton passes $0{\cdot}30\mu$ but not $0{\cdot}234\mu$ or any smaller membrane: and this is a point of some interest since (as she shows in a paper now in the press) this virus does not pass through a L.3. Pasteur-Chamberland porcelain candle, although its pore size is about $2{\cdot}5\mu$.

By Elford's method of calculation, these figures would indicate a particle size of $15\mu\mu$ for the tobacco and yellow mosaic viruses, about 40-$50\mu\mu$ for aucuba mosaic, and $150\mu\mu$ for the *Hyoscyamus* virus. The value found for tobacco mosaic comes midway between Duggar's estimate of 30-40mμ and the recent estimate of 5mμ by Waugh and Vinson.

It is possible by the use of these membranes to separate two viruses occurring together in nature in the same plant. Dr. Hamilton's *Hyoscyamus* virus was passed through a series of membranes. It passed $0{\cdot}64\mu$ and $0{\cdot}30\mu$ with characters unchanged; after passage through $0{\cdot}234\mu$, $0{\cdot}209\mu$, and $0{\cdot}120\mu$ the disease produced was of different type, and further investigation has shown that the virus passing the smaller membranes is entirely different in its properties from the other larger virus it accompanied, and it is possible to separate the two by other methods than filtration.

Constitution of Tantalum and Niobium

THESE two elements of the vanadium group have properties very unfavourable to mass-spectrum analysis and all attempts previously reported have been completely unsuccessful. I have now been able to obtain their mass lines, owing to the kindness of Dr. P. Kronenberg of Berlin, who has prepared for me specimens of the pentafluorides. These solids are slightly volatile but their great chemical activity makes them troublesome to deal with. If, however, they are volatilised in the discharge tube itself, it is possible to obtain, at least intermittently, a discharge which contains the metallic ions. Under these conditions the data are not complete, but one result is beyond doubt, and this is, that notwithstanding their fractional chemical atomic weights, both elements are essentially simple.

Tantalum, which was investigated first, gave a strong line at 181 followed by a diminishing series 200, 219 . . . due to TaF, TaF_2 . . . Neither the expected isotope 183 nor any other could be detected even to one-fiftieth of the main line. The packing fraction of tantalum was estimated from the position of the line 200 among the mercury group to be -4. Owing to certain experimental difficulties, this is only to be regarded as a rough provisional value, but it eliminates any possibility of an abnormally high mass. Correcting to the chemical scale, this value gives

$$\text{Atomic weight of tantalum} = 180{\cdot}89 \pm 0{\cdot}07.$$

Niobium behaved in exactly the same way, giving a single line at 93 and fluorides at 102, 121 . . . It has not been possible to measure the packing fraction of niobium with accuracy, but direct comparison of the line 93 with line 85 (SiF_3) suggests a large negative value, about -8. This gives on the chemical scale

$$\text{Atomic weight of niobium} = 92{\cdot}90 \pm 0{\cdot}05.$$

The atomic weights of these elements given by chemical methods have always been regarded as unsatisfactory, and these results suggest that the present international values, 181·4 and 93·3, are considerably too high.

Vibrations in Solid Rods

IN connexion with the study of vibrating metal rods, a method of investigation has been devised which promises to lead to a number of new and interesting results. The experiment consists in tapping a rod at one end with a small hammer, and then making visible the train of waves which occur as a result of the impact. This is accomplished in the following manner.

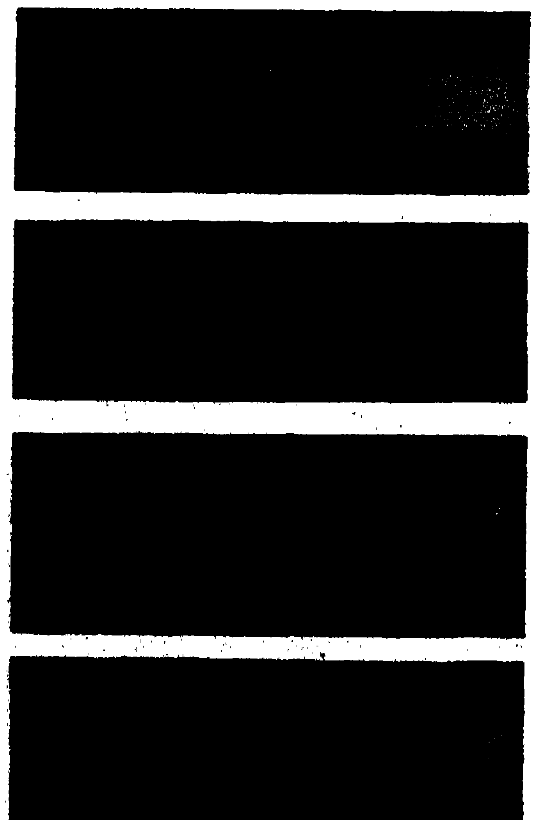

FIG. 1.

To the end of the rod opposite that which is tapped is cemented a piece of piezo-electric crystal, for example, quartz or tourmaline, which converts the vibrations at that point to an alternating voltage.

This voltage is amplified and impressed on a cathode ray oscillograph, which has in connexion with it a properly synchronised time-axis device. The hammer is driven by a synchronous motor and strikes the end of the rod ten times a second. By proper adjustment throughout, each train of waves occurs on the oscillograph screen exactly superposed on the preceding train, so that a steady picture is obtained representative of the periodic displacements of the end of the rod with time. This graph, as it really is, may be photographed if desired.

It has been found that in most cases the waves are quite complex, being combinations of longitudinal, flexural, and possibly other modes of vibration. In order to separate these component frequencies, the voltage from the amplifier may be passed through a tuned circuit and the selected frequency then impressed on the oscillograph. It is thus possible to pick out vibrations of different types.

In Fig. 1 are shown several examples of waves which occur in duralumin rods when they are struck with a hammer. The fourth curve shows the predominating frequency present in the wave immediately above it, this analysis being obtained with the use of the tuned circuit previously mentioned.

By measuring the decrement of any desired wave, the coefficient of solid viscosity corresponding to that frequency may be calculated, and it is believed that considerably greater accuracy may be obtained in this way than has been possible with previous, more indirect methods. From the fourth curve in Fig. 1, which corresponds to the fundamental mode of longitudinal vibration for a certain duralumin rod, the logarithmic decrement was found to be 0·016, giving a value for the coefficient of solid viscosity of $4 \cdot 6 \times 10^4$. Although this rod was of duralumin, it is interesting to note that in 1922 Dr. R. W. Boyle [1] suggested that when the coefficient was accurately determined for steel (in many respects similar to duralumin), its order would probably be not greater than 10^5. The variation of this coefficient with frequency and amplitude of vibration remains to be determined, but when this matter is examined in greater detail, it is probable that a clearer understanding of the nature of solid viscosity, including hysteresis, may be forthcoming.

Mean Lives of the Lowest Metastable States in Neutral Oxygen, and Intensities of Lines Arising therefrom

Transitions from the lowest metastable levels in the OI spectrum are of interest as occurring in nebular and auroral spectra. The red lines $^3P_{2,1} - {}^1D_2$ (λλ6300, 6364), which have been produced in the laboratory by Hopfield,[1] have been identified by Paschen [2] as occurring in the spectra of some of the nebulæ, and by Sommer [3] as occurring in the spectrum of the night sky, while the line $^1D_2 - {}^1S_0$ (λ5577) is the well-known auroral green line first identified by McLennan. A theoretical calculation of the intensities of such transitions and the mean lives of the metastable states is therefore of interest.

These 'forbidden' transitions are evidently due to quadripole radiation, for the Zeeman effect in the auroral green line has been shown by Frerichs and Campbell [4] to be in agreement with the supposition of quadripole radiation, but inconsistent with the hypothesis of perturbed dipole radiation. In a forthcoming paper in the *Proceedings of the Royal Society*, I have made the corresponding calculations for OIII with reference to nebular lines, on the assumption of quadripole radiation.[5] The final results are expressed in terms of integrals of radial wave functions, thus depending only on the central field of force adopted, and these integrals can be calculated from a comparison of calculated and observed separations between the levels. Now, Heisenberg [6] has shown recently that the wave equation for the lowest levels of an atom in which there are n electrons outside closed shells only differs, in first approximation, from that of an atom in which there are n 'holes' (that is, a closed shell is incomplete by n electrons) in that a different central field of force must be adopted. This enables the method outlined above for OIII to be applied immediately to the case in hand, thus yielding the following results for the $2p^4$ terms in OI:

Line.	Relative Intensity (per atom).
$^3P_2 - {}^1D_2$ (λ6300)	3
$^3P_1 - {}^1D_2$ (λ6364)	1
$^3P_0 - {}^1D_2$ (λ6391)	4×10^{-4}
$^1D_2 - {}^1S_0$ (λ5577)	1
$^3P_2 - {}^1S_0$ (not observed)	10^{-7}
$^3P_1 - {}^1S_0$,,	2×10^{-3}
$^3P_0 - {}^1S_0$,,	0

Relative intensity of $^1D_2 - {}^1S_0$ to $^3P_2 - {}^1D_2 = 1400 : 1$
Mean life of $^1S_0$ state = 0·02 sec.
,, ,, $^1D_2$,, = 100 sec.

The results are, of course, only approximate, the figures for $^1D_2 - {}^1S_0$ and the mean life of the $^1S_0$ state being less accurate than the others. The only direct comparison with observation is in the relative intensity of lines with $^1D_2$ as initial state. The relative intensity of $^3P_{2,1} - {}^1D_2$ is about 4 : 1 according to Hopfield,[1] while for the nebula N.G.C. 7027 the ratio is about 5 : 2 according to Wright.[2] The line $^3P_0 - {}^1D_2$ (λ6391) is not observed in the nebulæ, but was weakly observed in the laboratory according to Paschen.[2] These results are in satisfactory agreement with the above. In a subsequent paper, however, Paschen [7] gives the relative intensity of $^3P_{2,1,0} - {}^1D_2$ as 5 : 3 : 1. If this were really the case, it would, of course, be in serious disagreement with the theory.

The figures for the mean lives throw some light on conditions in the nebulæ and the auroral regions. If it becomes definitely established that the red lines (λλ6300, 6364) occur in the auroral spectrum, the observed relative intensity of λ5577 to λ6300, combined with the above calculated relative intensity *per atom*, would furnish the relative number of atoms in the $^1S_0$ and $^1D_2$ states, which would be of interest in connexion with possible processes of excitation in the upper atmosphere.

I wish to thank Mr. M. F. Crawford for valuable discussion of the experimental data.

Layer-chain Structures of Thallium Di-Alkyl Halides

DURING the last year we have been studying the crystal structures of a series of compounds R_2TlX, which prove to be of some interest in view of the recent work on the rotation of molecules in crystals. The dimethyl thallium halides are tetragonal and the others orthorhombic, pseudo-tetragonal, and all show

a sodium chloride-like structure. Layers of TlX parallel to the *ab* plane are spaced out at distances depending on the length of the alkyl chains, which are attached to the thallium ions perpendicularly to these layers. The *a* and *b* cell dimensions are almost independent of the alkyl group and vary between 4·29 A. (chloride) and 4·76 A. (iodide). These spacings, which, except in the case of the iodide, are much lower than the values 4·85 A. (Müller) [1] and 4·76 A. (Bernal) [2] found for the distance between rotating chains, are in agreement with other indications that the chains in these compounds do not rotate.

There is evidence that the chains are not of the usual zigzag pattern, but are like Müller and Shearer's [3] suggested type 3, and the two covalencies of the central thallium atom in the chain are at 180°.

We have also studied the double refraction of these compounds, which combine the characteristics of both chain and layer structures. The following table shows that the sign of the double refraction may be either positive or negative according as the influence of the chain or layer character is the greater (cf. Bernal's observation, loc. cit., of negative double refraction in an alkyl ammonium chloride).

Sign of Double Refraction

X	$TlMe_2X$	$TlEt_2X$	$TlPr_2X$
I	–	–	–
Br	–	+	–
Cl	+	+	+

The variations can be satisfactorily explained by a simple extension of the method of Wooster,[4] by taking into account the relative importance of the various atoms in their contribution to the refraction.

A detailed account is in preparation.

A Metagalactic Cloud between Perseus and Pegasus

During the course of an investigation concerning the occurrence of bright metagalactic clusters, I have found between the constellations Perseus and Pegasus a number of clusters of anagalactic nebulæ which seem to form subsystems of an extended metagalactic cloud. This cosmical unit can be traced in Herschel's G.C. and is very conspicuous in the N.G.C. and I.C. material. On the whole, the supersystem is composed of fifteen or nineteen larger and smaller metagalactic clusters, situated between $\alpha = 23^h$, $\delta = +20°$ and $\alpha = 3^h\ 20^m$, $\delta = +48°$. All the subsystems are arranged in a zone reminding one of a region of the galaxy. The well-known Perseus cluster, discovered by M. Wolf, is involved on the north-following boundary, and the Pisces group (E. P. Hubble) near the central region of the cloud. A connexion between the metagalactic cloud in question and the Pegasus cluster is suggested.

450 N.G.C. objects are situated in the general field of the cloud, and the main bulk of these objects seem to be physical members of the cloud. The density of nebulæ in this part of the sky is remarkable. Thus we count 117 N.G.C. objects in the central region, but only 8 and 3 respectively in equal large areas, situated north and south of the said region. Translating the literal symbols of magnitudes given in N.G.C. into numerical values of total magnitudes, we obtain for 312 nebulæ, obviously belonging to the cloud, a frequency-curve of total magnitudes remarkably similar to the corresponding curve for the objects in the bright Virgo cloud, discovered and studied by H. Shapley. Thus the curve also shows the 'hump' in its ascending branch, earlier found by W. Baade in the case of the Ursa Major cluster.

The distance of the bright metagalactic supercluster (or cloud of galaxies) can be assigned the preliminary value of 10×10^6 light-years, the extension and depth of the cloud to about 30×10^6 light-years in accordance with the distances found for the known clusters of faint nebulæ involved in the metagalactic cloud here considered.

Energy of Dissociation of Nitrogen

In Nature of June 11, page 870, A. K. Datta gives the energy of dissociation of nitrogen as deduced from his measurements of the absorption spectrum of nitrous oxide.

The value − 18·1 appears to have been used for the heat of formation of the latter gas. This value is so suspect that a redetermination has been made in this department,[1] and similar work is in progress at the National Physical Laboratory.[2] Using the value[1] − 20·6, Datta's figure becomes $9{\cdot}0_0$ volts or 208 kilocalories.

The following table includes the more recent values obtained by various methods, and shows that the energy of dissociation of nitrogen is now comparatively well known:

Birge . . .	9·04 ± 0·2 volts	Nature, 122, 842; 1928 *T. Faraday Soc.*, 25, 713; 1929
Kaplan . .	9·0 volts	*Proc. Nat. Acad.*, 15, 226; 1929
Tate and Lozier	8·4 ± 0·5 volts	*Phys. Rev.*, 39, 224; 1932
Datta (corrected)	9·0 volts	Nature, 129, 870; 1932

Fatuoids or False Wild Oats

Mr. E. T. Jones's observations [1] are, as he remarks, highly important in their bearing on the problem of the origin of fatuoids or false wild oats. The conclusions to be drawn from these observations are, however, in my opinion, precisely opposite to those drawn by Mr. Jones. His data, showing that two or more genes are concerned in the production of the fatuoid complex in diploid × tetraploid oat hybrids surely support my assumption that the fatuoid complex of hexaploids is determined by a number of linked genes. Therefore, for fatuoids to arise by gene mutation, as he considers they do, it is necessary to assume mutation occurring simultaneously in all these genes—a rather improbable assumption. The change in dominance, stressed by Mr. Jones, has in other cases been shown to be directly attributable to polyploidy.

As for the absence of crossing-over in fatuoids, this is a characteristic of chromosome aberrations in

general, now very widely established. I must confess inability to see how it can support the gene mutation theory of the origin of fatuoids, but on the chromosome aberration theory it is expected, since chromosomes *B* and *C* are not complete homologues. They are considered to be homologous along parts of their length, but not in the region bearing the fatuoid genes. Hence, complete linkage or absence of crossing-over is expected *in this region*.

In a paper [2] on the analogous speltoid mutations of wheat, I stated that the formulæ for fatuoids and speltoids there presented, and quoted now by Mr. Jones, were provisional and would probably have to be modified. Five years' further cyto-genetic work, with greatly improved cytological technique, has demonstrated the need for modification, but not for any fundamental changes in the original hypotheses and formulæ. Instead of duplication of whole chromosomes, it is now clear that only parts of chromosomes are duplicated in some mutant strains. The hypothesis that fatuoids arise through chromosome aberrations is, I consider, now so well established for most strains I have studied (including strains of Series *A*) that it appears to me unnecessary at present to resort to the alternative gene mutation hypothesis for those cases in which the evidence of aberration is not yet so clear.

It is, however, impossible here to summarise adequately the voluminous data upon which this opinion is based. They will be assembled for publication after the present season's work is completed. The object of the present note is to answer Mr. Jones's criticisms by indicating the very different interpretation which it is possible to place upon his observations. The observations themselves are certainly very important, for their bearing not only on this problem but also on the wider problem of the origin of cultivated oats.

[1] NATURE, 129, 617, April 23, 1932.
[2] *J. Genetics*, 20; 1928.

IN a letter recently contributed to these columns,[1] Mr. J. Philp makes certain statements and arrives at certain conclusions in respect of the subject-matter of a communication made by me to this journal [2] which require consideration.

In reading through Mr. Philp's letter it appears to me that he has not clearly apprehended the facts stated in my communication. From my *descriptive* statement that "Segregates have appeared in this cross [*A. barbata* × *A. brevis*] in which the basal articulation and basal pubescence characters of the *A. barbata* parent occur in association with the awn and grain-apex of *A. brevis* type . . ." he concludes that I maintain that grain-apex, as well as awn, is linked with the fatuoid complex, although in an earlier part of the same paragraph I definitely refer to the fatuoid complex as consisting of the characters *articulation, basal pubescence*, and *awn*. I have expressed no view as to whether the grain-apex is or is not linked with the fatuoid complex. The cross-over types in question, so far as the fatuoid problem is concerned, relate to the appearance of a weak awn (of *A. brevis* type) in association with a horse-shoe shaped base and dense basal pubescence (a combination of characters not hitherto recorded); and conversely, the twisted geniculate awn (of *A. barbata* type) in association with a 'cultivated' type of base.

The other misapprehension, and a very fundamental one, relates to a statement (a presumption on Mr. Philp's part) that my observations are based upon a triploid hybrid. In the second paragraph of my communication it is clearly indicated that the cross-over types under consideration are F_3 segregates possessing the diploid chromosome number.

As Mr. Philp's letter is based almost entirely upon these two main issues, his criticisms and conclusions require no further comment.

Prof. C. L. Huskins puts forward the view that it is possible to explain the observed cross-over types as evidence in support of the chromosome aberration hypothesis.

The cross-over types in question exhibit a breakup of the fatuoid complex into two parts. We have, therefore, on the basis of the present evidence, to examine the case for the probability or improbability of simultaneous mutations occurring in these two 'units'. On the basis of the modified gene-mutation hypothesis, the mutations are considered to occur not in the *B* chromosome but in *C*. This is a point of importance when making comparisons of the expectations of crossing-over, or of gene mutations, in Series-*A* hexaploid fatuoids with the 'diploid' cross-over types of the diploid-tetraploid cross. In the latter, the cross-over affects both the *B* and *C* chromosomes. The necessity for assuming that the occurrence of simultaneous mutation in both 'units' of the gene complex in Series-*A* fatuoids depends, therefore, upon whether the linkage in the corresponding epistatic genes in the *C* chromosome is of the same degree as that between the genes of the *B* chromosome, which are fundamental in the determination of the fatuoid characteristics; and whether the epistatic genes in *C* are numerically similar to those in *B*. There is evidence, however, that all mutations occurring in *C* are not of the same degree of complexity, and as examples of the divergent mutant types thus produced, I may mention the already recorded strongly awned Types *A*, *B*, and *C*, and the fatuoid of Golden Rain.[3] From these observations it may be inferred that simultaneous mutation does take place, but not always in the same degree. On its extent, therefore, depends the appearance of fatuoids, sub-fatuoids, semi-fatuoids, or simply strongly awned types, and their relative frequency must depend upon the extent to which one gene or set of genes mutates in relation to the others. Probability, therefore, is not so very remote.

With regard to the homology and genic identity of the *B* and *C* chromosomes, that is, assuming for the moment that we are dealing with a case of whole chromosome aberration as originally postulated by Prof. Huskins, I know of no positive evidence which proves that the *B* and *C* chromosomes carry identical genes throughout the whole of their length, excepting, of course, those which determine the fatuoid complex. There is, however, on the contrary, evidence to show that in some oat varieties genes affecting spikelet number are present and also genes affecting the morphological character of the awn.[3] As Prof. Huskins has himself put forward the view that the *B* and *C* chromosomes have had a separate specific origin, their identity in gene constitution is on this account scarcely to be expected. On the basis of the chromosome aberration formulæ, it has to be assumed that the *B* and *C* chromosomes are identical and interchangeable without any apparent phenotypical changes other than those appertaining to the fatuoid complex. If, however, Prof. Huskins wishes to maintain, as now appears to be the case, that in most strains what we have is not whole chromosome aberration but a duplication of only parts of the chromosome, then surely some fundamental modification of the formulæ is necessary. This, in his letter, he does not permit. As, however, the critical details of the application of this modified interpretation of the chromosome aberration hypothesis have not yet been

published, to comment upon this aspect of the problem would be purely hypothetical.

Genetical data showing the inadequacy of the chromosome aberration hypothesis to explain Series-*A* fatuoid phenomena have already been published.[3] Recently, on the basis of cytological investigations of material supplied by Prof. Huskins, Nishiyama [4] has corroborated my conclusions in respect of Series-*A* fatuoids, namely, that they arise by mutations occurring in the *C* chromosome.

The validity of the chromosome aberration hypothesis as such does not necessarily arise in these discussions; the point at issue is its applicability as an explanation of the origin and behaviour of Series-*A* fatuoids, sub-fatuoids, and semi-fatuoid types which show regular and simple Mendelian segregation and possess normal ($2n = 42$) chromosome numbers.

A theoretical case for opposite conclusions can very probably be made out, based upon the assumption of some form of chromosome duplication, but until the occurrence of the latter is substantiated, there are no convincing reasons why we should depart from the principle of complex gene mutation as first postulated by Nilsson-Ehle.[5]

Inheritance of Fluorescence in Rye-Grass

I AM engaged on the cytology and genetics of perennial rye-grass (*Lolium perenne* L.) and Italian rye-grass (*L. multiflorum* Lam.). It is commonly believed that many plants intermediate between these two species are a result of hybridisation, and it was the object of the work to investigate this hybridism. In the course of the investigations, the inheritance of fluorescence of roots under ultra-violet light[1] has been studied. The fluorescent character which is found in Italian rye-grass and strains of 'false' perennial but not in true perennial rye-grass offered an opportunity for rapid classification of types.

Twenty-eight parent plants were tested for fluorescence after allowing tillers to grow roots on filter paper. Sixteen of these were 'non-fluorescent' and twelve were 'fluorescent'. These plants were self-pollinated by using cellophane bags, and the work was carried out under controlled conditions in the glasshouse. The seedlings resulting from the self-pollination were examined for fluorescence. Of 1459 seedlings tested from the 'non-fluorescent' plants, all except one (probably a contamination) were 'non-fluorescent'. Nine of the 'fluorescent' plants gave 100 per cent 'fluorescent' seedlings, the total number tested from these plants being 885. The remaining three 'fluorescent' plants produced both 'fluorescent' and 'non-fluorescent' seedlings. One of these gave 191 'fluorescent' and 65 'non-fluorescent' (a ratio of 2·94 : 1), another 126 and 40 (a ratio of 3·15 : 1), and a third 8 'fluorescent' and one 'non-fluorescent'. Insufficient seeds to give a significant result were obtained from this plant. The first two results, however, appear to indicate that fluorescence depends on a single Mendelian factor, and that the two parent plants are heterozygous for this factor.

The relationship between fluorescence and some botanical characters of the plants is of interest. The flowering glumes of the 'non-fluorescent' plants were awnless and the leaves conduplicate in the bud. The flowering glumes of the plants which produced 100 per cent 'fluorescent' seedlings were awned and the leaves convolute in the bud, although, as is usual in *L. multiflorum*, the basal flowering glumes of the lower spikelets were often awnless. The three parent plants which produced both 'fluorescent' and 'non-fluorescent' seedlings differed from one another in awn characters. One was awnless, in the second there were a few flowering glumes with very short awns, while in the third some of the flowering glumes produced either short or well-developed awns. They were similar, however, in that in each case the leaves in the bud were conduplicate.

This work is being continued.

A New Method for Mitochondria

I HAVE recently found that quinone (parabenzoquinone) has an intense fixative action upon mitochondria. It is best to treat tissues for an hour with quinone dissolved in saline first, and then to transfer them to any fixative one may choose. I have found this much preferable to using quinone-saline alone or mixing it with any other fixative. The quinone may be at any concentration from 0·05 per cent for delicate tissues (such as kidney) to 0·5 per cent for liver. Plenty of fluid should be used. The saline should be roughly isotonic with the blood of the animal used, but if the quinone is used at 0·5 per cent, it is as well to make the saline 0·1 per cent less concentrated than usual, so as to avoid having the fluid hypertonic. Surprisingly enough, Carnoy's fluid is one of the best fixatives to use after quinone. I have used the formula without chloroform.

It is remarkable that one hour's treatment with such a weak solution as 0·05 per cent of quinone should render the mitochondria insoluble in the fixative which is regarded as the most destructive of them. Bouin's fluid is also excellent after quinone-saline. One may stain with iron hæmatoxylin, or by Altmann's or Benda's method. In using Altmann's method, a convenient differentiator is one part of absolute alcohol saturated with picric acid to seven parts of 30 per cent alcohol, used cold. If one uses Carnoy's fluid and follows with Altmann's method, one may fix one's tissue in the morning and have finished slides of mitochondria in the evening. No special mordantage is required for subsequent staining in Benda's alizarin and crystal violet, which gives good results after Carnoy's fluid.

The technique has been worked out mostly with the liver of the newt and the liver and kidney of the guinea-pig. No advantage has been found in substituting other quinones for parabenzoquinone.

Full details of the technique, with an account of the research leading up to it, will be published in the *Quarterly Journal of Microscopical Science*.

I wish to thank Prof. E. S. Goodrich and Dr. H. M. Carleton for helpful criticism of my slides, and Mr. C. E. J. Crawford for chemical advice.

Research Items

Indian Village Godlings.—In an account of the cult of Bāro Bhāiyā, a form of 'demon worship' prevalent in Eastern Bengal (*J. and Proc. Asiatic Society of Bengal*, N.S., vol. 26, No. 1), Mr. Chintaharan Chakravarti points out that no trace of the religious rites of the village folk of India, often very interesting, is found in any scriptural text, though the people retain palpable traces of undoubtedly ancient rites. In the cult of Bāro Bhāiyā, or the Twelve Brothers, as observed in Kotālīpādā in the district of Faridpur, the objects of worship are twelve brothers and their sister or mother. It is known also popularly as the cult of Vanadurgā (the mother of the twelve brothers) or Niśānātha. The brothers are described as demons and terrible in appearance. Any displeasure on their part brings disease and calamity. Vanadurgā has been described as a tree goddess, as her worship takes place under a tree and she has no separate image. There is no fixed time for the worship of these deities; but it usually takes place on Tuesdays and Saturdays and in the day-time. Generally no images are made; but there is an effigy of one of the brothers in a house in the village of Unaśiā. At Kotālīpādā the worship is performed at the base of a big Aśvattha tree, the place being known as Niśāi-kholā, or the place of worship of Niśāi. There is no provision for daily worship as in the temples. The rites of worship follow those laid down in the scriptures with regard to worship in general, except that the heads of the sacrificed animals are not taken back, but are left in the hollow of a tree. The mantras used are all in Sanskrit, and the whole worship has been made to conform to the Tantra form, the deities being given Sivaite implements and attributes, showing how a purely popular cult has been affiliated to Aryandom.

Fortifications at Tell el-Ajjūl.—Lieut.-Col. N. P. Clarke offers a reconstruction of the defences of Tell el-Ajjūl, Southern Palestine, so far as revealed by excavation to date, in *Ancient Egypt*, pt. 1, 1932. On the south-west side the tell is protected by the Wady Ghazzeh; on the remaining three sides by the Great Fosse, from which the earth was thrown out on the hill to form a slope of 35°; while the slope of the counterscarp is 1 in 4. The dominance of the site over the neighbourhood and its strength were due entirely to artificial works. On the north-east the ground was undulating and probably afforded cover to an attacking enemy. As might be expected, there appears to have been a work in this direction to deny this ground to an enemy. A pit has been discovered, the earth from which, contrary to normal practice, has been thrown *outwards* to form a bank. This was a self-contained outpost, the great depth of which gave perfect cover from archery. A tunnel leads from near the main entrance on the north-east side to the work, which holds, possibly, one hundred men. A sunken road also leads from the tell to the pit. A similar pit, which was probably also connected with the tell by a tunnel, lies several hundred yards to the north. These belong to the earliest system of defence, and there is evidence to suggest that they are of the copper age (3500–3000 B.C.) or shortly after. The northern trenched enclosure includes the pit outpost and must be later. A different system of trenches runs off the north-east corner; but instead of the irregular lines of the pits, the trenches run in long straight lines. They strengthen the entrance of the tell itself by outflanking any attack on the gates.

The Trunk of a Mammoth.—Some eight years ago a Tungus hunter found a well-preserved mammoth's trunk in the Bolshaya Baraniha River in Siberia, the first proboscis-tip to have been seen since the days of the palæolithic age (Science Service, Washington, D.C.). After various wanderings, the proboscis-tip reached the Museum in Leningrad, and it has now been described by Dr. G. Flerof. In general, there is a resemblance to the trunk-tip of the Indian elephant, but the 'lip' is much longer and wider than that of any modern elephant and gives the entire tip a bilobed appearance. Its adaptation is towards the efficient plucking of large bunches of grass or moss, at which it would be more adept than Indian or African elephants, which feed largely upon the leaves of trees and shrubs. An interesting point, the report states, is that European cave drawings sometimes represent the mammoth as having a bilobed trunk-tip, and the recent discovery of the frozen specimen shows again how keen was the perception of the artists of the old stone age, and how accurate were their drawings.

Bibliography of the Sardines.—The sardine is of enormous commercial importance in both Europe and America. But throughout their entire existence the sardine fishing, curing, and canning industries have always suffered from disconcerting fluctuations in the stocks of the various sardine species. On both sides of the Atlantic much research has therefore been undertaken in an as yet more or less unsuccessful attempt to elucidate the life histories of these fishes and to understand the causes underlying their erratic habits. A vast and scattered literature has therefore grown up around them. In order to facilitate reference to all the published works on *Sardina pilchardus* (Europe), *S. melanosticta* (Japan), *S. ocellata* (South Africa), *S. sajax* (west coast of South America), and *S. caerulea* (west coast of North America), a bibliography has been compiled and is now published as *Fish Bulletin* No. 36 of the Bureau of Commercial Fisheries, California. With few exceptions, the compiler, or her associates, has consulted every paper or publication listed, and a brief summary of the contents of each is appended immediately following the title. The usual system of listing the authors alphabetically and the papers of each author chronologically has been adopted. This carefully compiled and very full bibliography should prove of immense benefit to all students of the sardine in the spheres of both natural history and of commerce. Copies are offered free of charge to interested persons and in exchange for the publications of other bodies engaged in marine research. Address: California State Fisheries Laboratory, Terminal Island, California.

Indian Fungi.—Dr. E. J. Butler and Dr. G. R. Bisby have recently published a book which attempts to collect together our knowledge of the fungi of India (The Imperial Council for Agricultural Research, Scientific Monograph No. 1: "The Fungi of India". Government of India Central Publication Branch, Calcutta, 1931, pp. 237, 11*s*.). The authors have consulted more than five hundred scientific papers, and have compiled a descriptive list which should help the student of mycology in the large area under review. The introduction is perhaps the most interesting part for the general student. Comparisons of the fungus floras of India and Europe are made, and show that more than twenty-three per cent of the total number of species are also represented in Europe. This is more than the proportion of phanerogams, for only six per cent of the number of species of flowering

plants occur also in Europe. There are other interesting comparisons of distribution which should interest the ecologist as well as the student of mycology. An extensive list of synonyms is given and will go far towards clearing up many difficulties of nomenclature.

Twisted Trees.—Recent observations of trees the trunks of which have a clockwise or counter-clockwise twist appear to show that this is not produced either by the wind or by any reaction to the movement of the sun. Mr. F. Knorr (*J. Heredity*, vol. 23, No. 2) has made a number of further observations on conifers in California. In 1926, search disclosed 486 twisted trees, in 44 per cent of which the twist was clockwise, 56 per cent the reverse. The following year, with still larger numbers belonging to six species, 27 per cent of the trees were found to be twisted, 52 per cent of them clockwise. In later years it was found that only part of the species in a particular area would show twisting. In the giant redwood and in certain deciduous trees, secondary growths showed the same twist as the parent trees. Examination of conifer seedlings showed that the twisting begins with the woody thickening both in stem and root, while in older trees the branches and twigs show the same twist as the main trunk, although the intensity of twist may vary to some extent. These observations all suggest that twisting of the wood may be a genetic character, and if this is the case, the habit of western lumbermen in leaving twisted trees for seeding purposes because they are of less economic value will be very unfortunate in its effects.

Microscopic Determination of Ore Minerals.—The optical and microchemical study of opaque minerals is now reaching a mature stage in its development. The most recent work on the subject in English (*U.S. Geol. Surv., Bull.* 825, 1931, pp. 204) has been written by M. N. Short, who has himself been occupied with the investigation of improved methods during the last four years. From a research point of view, the book is noteworthy because, for the first time, full determinative tables are given incorporating the effects of polarised light on polished surfaces of ore minerals. A far-reaching and critical study of qualitative microchemical tests for elements forms the basis of another and equally useful set of determinative tables. A combination of these two methods with the etching processes devised by Davy and Farnham, Murdoch, and others brings the whole technique up to the level of reliability attained by the better known petrographic methods involving the use of transmitted light. The work concludes with a list of specific tests for minerals, the latter being arranged alphabetically. It is obtainable from the Superintendent of Documents, Washington, D.C., at a cost of 60 cents.

Boring for Oil in Egypt.—The third section of the Report on "Boring for Oil in Egypt" (Cairo: Government Press, 1931) deals with the eastern desert and adjoining islands. Mr. T. Sutton Bowman gives a full and detailed account of his investigations of the samples from various wells drilled in this territory, and the report is of note as being one of the few lengthy expositions on the use of sedimentary petrography ('heavy' minerals, etc.) in oilfield (subsurface) problems, published outside America. The specialist in this subject will profit by reading Mr. Bowman's account of his methods and findings, and while some of the former are open to criticism, there is little doubt that this region has provided yet another case of the value of intensive petrological work in competent hands. The stratigrapher will find that the problem of the Nubian Sandstone has been re-attacked, and, although admittedly the evidence is at present of local significance and based on work which is incomplete, the sharp petrographic distinction established between the Cenomanian on one hand, and the Turonian and Santonian and true Nubian Sandstone on the other, is indicative of at least a promising means of analysing this composite lithology in other regions of Egypt.

Greenland Weather.—The weather of Greenland has importance in the institution of a great circle flying route between Great Britain and North America, and was investigated by the recent British Arctic Air-Route Expedition. Some results are given in a paper by Mr. S. T. A. Mirrlees in the *Geographical Journal* for July. During summer, visibility on the east coast was good when once the low fog belt over the pack ice was left behind, and during winter, apart from the short hours of daylight, it was fairly good. Winds on the east coast were light in summer, but gales were very frequent in winter and of great violence. They were, however, local and might possibly be avoided if choice of landing places were available. The observations from the ice cap station are, however, the most important and cover a period of about eight months. Poor visibility showed a frequency of 44 per cent, but probably drifting snow accounted for fully half of these occasions, and since the drift layer is shallow, it would not affect aviation. Strong northerly winds were frequent and calms rare, but gales were less common than on the coast. The average temperature of the air on the ice cap varied from 2° F. in September to - 33° in February, and the variation of temperature was great from day to day and depended on the direction and force of the wind. Inversion of temperature at heights of 1000-1500 ft. was found to be common, and the lowest temperature recorded at those heights was - 14° F., but there are no records for June, July, October, and November. Cloudiness at the ice cap station was small. Flight-Lieut. D'Aeth concludes that a summer flying route over Greenland would be entirely practicable, but that winter flying would be difficult and necessitate an efficient ground organisation.

Structure of Atomic Nuclei.—Now that neutrons have been detected as probable products of the artificial disintegration of light elements, it will be necessary to accommodate them in some way in the scheme of nuclear structures. An attempt at this has been made by F. Perrin (*J. Physique*, May, p. 96, S.). In his first scheme, the particles employed for the light elements are helium nuclei (α), neutrons (ω) and protons (π). The scheme explains nicely the strong emission of neutrons, without protons, in the artificial disintegration of beryllium, the structure of which becomes $2\alpha\ 1\omega$, and is otherwise fairly satisfactory, except in the case of nitrogen, which, written as $3\alpha\ 1\omega\ 1\pi$, should apparently be capable of giving neutrons as well as protons, whereas the former are not emitted. Largely on this account, a second scheme, which is highly suggestive, has also been proposed, in which the protons are supposed linked up with neutrons to give 'demihelions' (η), particles of mass 2 and unit charge, which are in fact known now through the discovery of the heavy 'hydrogen' isotope spectroscopically. On this scheme beryllium remains the same as before, but nitrogen becomes $3\alpha\ 1\eta$. The important implication of this second scheme is that the particles produced in artificial disintegration which have been generally supposed to be protons may actually be demihelions. The experimental evidence already extant should be adequate to decide this point, but it is noted that it could at least account for certain features of Blackett's photographs of the artificial disintegration of nitrogen. Perrin also gives

schemes for the nuclear structure of the elements from neon to potassium, analogous to his second scheme for the lighter elements, but with the modification that the maximum number of α-particles which could occur on purely numerical grounds is not employed, to obtain agreement with the results of disintegration experiments. It is interesting to note that there is some indication from this of why potassium (41) should have a natural radioactivity.

The Bleaching of Cellulose Materials.—In 1927, Clibbens and Ridge, of the Shirley Institute, carried out some important work on the action of chlorous bleach liquors on cotton, and revealed the surprising fact that in such cases the degradation of the cellulose was most rapid at a *p*H value of about 7, that is, at the neutral point. Subsequent work by Kauffmann, Weiss, and others, along different lines, has led to the same conclusions, although none of the theories advanced in explanation is entirely satisfactory, since they ignore the effects of variations in the concentration of cellulose. The problem has now been attacked from the point of view of the bleaching of wood cellulose by F. H. Yorston, of the Canadian Forest Products Laboratory (*Proc. of the Canadian Pulp and Paper Assoc.*, p. 31; 1932), who has found that an experimental bleaching mixture may be buffered to a *p*H value of 8·8-9·2 by addition of light magnesia, increase in acidity by neutralisation of the free lime by carbon dioxide being thereby avoided. In addition, it was possible to follow the rate of reduction, at *p*H 9, of hypochlorite by pulps which had already consumed various amounts of bleach, and to show that this reaction is monomolecular with respect to hypochlorite. It is concluded that the proportion of those substances present in the pulp in relatively high concentrations (for example, celluloses and pentosans) is probably little changed by the action of the hypochlorite, especially if allowances are made for the effect of the oxidation of soluble lignins on the apparent rate of reduction of hypochlorite and for the autodecomposition of the hypochlorite itself. An additional observation of interest is the superior colour of pulps bleached in an alkaline medium.

Astronomical Topics

Comets.—It is now established that there was a nebulous object near Newman's comet on the evenings of June 25 and 29. *U.A.I.Circ.* 392 contains a letter from Dr. Schmitt stating that he observed the object visually on June 29 with the Algiers equatorial, and also found it on his plates; he then examined the two exposures made on June 25, and found two images that indicated nearly the same motion as that of Newman's comet, which was registered on the same plate. On the first four days of July, observers at Bergedorf, Neubabelsberg, Heidelberg, Norwood, Yerkes failed to find any companions to Newman's comet, but on July 6 and 7, M. Delporte photographed two companion bodies at Uccle. Computations by Dr. M. Davidson make it unlikely that either of these is identical with the object of June 25 and 29.

A plausible conjecture is that Newman's comet has been expelling a series of vaporous masses, which have remained visible for a few days and then dissipated. The following table gives the distances of the three objects from Newman's comet:—First Object, June 25, E.100·43^{sec}, N.11′ 44·8″; June 29, E.114·42^{sec}, N.7′ 29·9″: Second Object, July 6, E.49·17^{sec}, S.3′ 34·9″; July 7, E.47·09^{sec}, S.1′ 45·4″: Third Object, July 6, W.65^{sec}, N.7′; July 7, W.68^{sec}, N.5′. It will be recalled that the great comet of 1882 expelled several portions. A sketch by C. L. Prince on Oct. 23 showed 4 nuclei (see Chambers' "The Story of the Comets", page 152, which also records that "on one occasion the comet seems to have thrown off a mass of matter which became, and for several days was observed as, a distinct comet").

Harvard Cards No. 224, 225, 227 give the following positions of comet 1932 *g* (Geddes). They are for the equinox of 1932·0. The observers at Cordoba were Dr. Bobone and Mr. Tretter; at La Plata, M. Dartayet. The magnitude was 9.

U.T.	R.A.	S.Decl.	Place.
June 25·9666	10h 43m 13·5s	81° 43′ 38″	La Plata.
27·0366	10 55 16·7	80 53 25	Cordoba.
27·9847	11 4 30·4	80 7 46	Cordoba.
29·0740	11 13 28·3	79 14 40	La Plata.

An erroneous position was given in *Card* 226; it is corrected in *Card* 227.

Hydrogen Content of the Stars.—Sir Arthur Eddington pointed out some years ago that the discordance between the calculated and observed brightness of the stars (the calculated one being about ten times too bright) could be removed by supposing a larger proportion of hydrogen in the stars than at that time seemed probable. He now gives reasons for believing that the proportion of hydrogen is actually large enough to remove the discrepancy (*Mon. Not. R.A.S.*, April). He shows that there are two solutions for the percentage of hydrogen, one 33 per cent., the other 99·5 per cent. He regards the smaller value as more probable, but does not absolutely rule out the larger one; five cases are worked out: the sun, Capella, Krueger 60, Algol, V Puppis. The agreement is close except in the case of the last star; it is suggested that the proportion of hydrogen may be greater in very massive stars.

Sir Arthur notes that a paper by Dr. B. Strömgren, which he did not receive until his own was nearly finished, deals with the same problem and reaches results in very good agreement with his. The existence of the second solution with the very high percentage of hydrogen was noticed by both investigators. Incidentally, Sir Arthur notes that he has changed his adopted value of the sun's absolute bolometric magnitude from 4·85 to 4·60.

A Hebrew Zodiac.—Mr. Moses B. Cotsworth, the well-known advocate of calendar reform, reproduces in his Pamphlet *W*, issued last year, a photograph of a zodiac, executed in mosaic work, which was discovered in 1929 under the ancient synagogue of Beth Alpha, in the valley of Jezreel; the date is conjectured to be the reign of the Emperor Justin, A.D. 518–527. Several of the figures depart considerably from the usual types. The Lion has its head towards the Virgin, the Scorpion towards the Archer, the Scales are in a man's hand (possibly to correct the anomaly that the Scales, being an inanimate object, break the circle of living things). The Hebrew names of the constellations are inserted, and several of them are distinctly legible in the reproduction: Shor the Bull, Ariyah the Lion, Bethulah the Virgin, Aqrab the Scorpion, Qesheth the Bow; the others are indistinct. Mr. Cotsworth states that a similar zodiac has since been discovered near Jericho. The late Mr. E. W. Maunder, in his "Astronomy of the Bible", collected several passages in the Old Testament that might be allusions to the signs of the zodiac; but this is the first distinctly Hebrew zodiac that has come under the notice of the writer of this note.

Annual Conference of the Museums Association

THE forty-third Annual Conference of the Museums Association was held at Birmingham on June 27–July 2, by invitation of the Lord Mayor and Corporation. This is the first time that the Association has visited the City. The University authorities very kindly placed lecture and office accommodation in Mason College, Edmund Street, at the disposal of the delegates, and here some two hundred members of the Association met under the presidency of Sir Henry Miers.

Owing to the prevailing financial conditions, the number of delegates was somewhat smaller than usual, but the Conference was noteworthy in that the social side was reduced to a minimum, and the numerous papers provoked animated, if not always appropriate, discussion.

In his presidential address, Sir Henry Miers gave an encouraging account of the past year's work. With the assistance of the Carnegie United Kingdom Trustees, grants have been made to certain municipal museums for the reorganisation of their collections, and short training courses for curators were held in London and Edinburgh. With the generous co-operation of the Carnegie Corporation of New York, surveys of museums in Canada and Africa were carried out by Sir Henry Miers and Mr. S. F. Markham, in the Mediterranean by the honorary treasurer and honorary secretary of the Association, and of the museums of Montreal by Dr. Cyril Fox, director of the National Museum of Wales. As a result of these surveys, directories of museums in Canada and Africa are in preparation which will contain data hitherto impossible to obtain even from the statistical departments of the appropriate governments.

Other matters of importance concerning museums which Sir Henry dealt with were co-operation between the national and provincial museums, and the expressed desire on the part of the national museums to assist so far as possible the small museums; the Board of Education pamphlet on "Museums and the Schools"; the work of the federations and the recent formation of a new federation, the South-Western Group of Museums and Art Galleries; co-operation with the British Broadcasting Corporation; and the improved status of the curator which is likely to result from the adoption of the diploma scheme. Sir Henry also commented on the increased usefulness of the *Museums Journal*, and reported that the membership of the Association had increased during the year from 516 to nearly 800.

At the conclusion of the address, the honorary treasurer (Alderman Charles Squire) presented Sir Henry with two bronze pieces of sculpture by Allan Howes, as a mark of the Association's appreciation of his services as president during the last four years.

Following the presidential address, Dr. G. F. Hill, director and principal librarian of the British Museum, opened a discussion on "Co-operation between National and Provincial Museums". He deplored the splitting up of collections and their subsequent distribution to different centres, as well as the retention locally of unique or historical specimens which fit properly into the series of our great national museums but obviously are out of place, unsafe, and lack true appreciation in the local museum. He also dealt with loan collections and the presentation of duplicates or casts and electrotypes to smaller museums by the larger institutions.

Subsequent speakers from the London museums elaborated these points, and their views appeared to meet with approval from their provincial colleagues. The remainder of the morning was occupied by Miss M. H. Keating's description of a travelling exhibition which she has prepared to illustrate child welfare work, and later in the day the delegates were able to inspect part of Miss Keating's exhibition.

Wednesday provided a varied programme of great interest. Dr. Alexander Scott described the work and methods of the British Museum laboratory in cleaning and restoring metal objects, and the results obtained, as illustrated by lantern-slides, aroused the enthusiasm of the audience and provoked numerous inquiries. Mr. S. L. Davison, of Port Sunlight, described the objects and methods of the Regional Federations of Museums, basing his remarks on his experience with the Lancashire and Cheshire Federation. "Modern Methods of Examining Pictures" was the subject of a delightful and practical exposition by Prof. A. P. Laurie, who made difficulties seem easy and constantly captured the admiration of his hearers by his wide knowledge of the history of pictures and artists. In the afternoon, Dr. L. J. Spencer explained how he illuminated the cases and specimens in the Mineral Department of the British Museum, and thus provoked a discussion of primary importance to the delegates. From the consideration of the lighting of museum cases to that of the illumination of a child's mind is no mean step, but the audience accomplished the transition safely and pleasantly under the guidance of Miss M. Champness, who described her work in the Newbury Museum.

From the subsequent discussion it appears that most curators are agreed that the handling of specimens by the child is of primary importance, while the 'once upon a time' method of telling a story, the provision of seats for the small listeners, and, if possible, the use of a special room away from adult interference, all contribute to the success of the instructional classes.

Most of Thursday morning was devoted to the annual business meeting, but the Association welcomed Mr. R. A. Rendall, of the B.B.C., who inaugurated a discussion on broadcasting and museums. Mr. Rendall outlined the educational policy of the Corporation, and hoped that the art galleries and museums might assist the broadcast of talks by arranging cognate exhibits, or by installing a loud-speaker in the institution for the benefit of organised discussion groups.

The morning of the last day of the Conference was devoted to a summary, by Mr. G. H. Hill, of publicity methods and extension work as at present practised by museums, and to Mr. D. Payler's description of his work in the Birmingham Museum in preparing economic and other exhibits. Dr. Cyril Fox, as chairman of the Education Committee, outlined the newly prepared scheme for a diploma to be awarded to curators after examination. Space does not permit the explanation here of the detailed proposals, but the scheme found favour, as it is definitely practicable and is based on a high enough standard to ensure the recognition of the diploma as a sound educational and curatorial qualification.

An official visit was paid by the Conference to the Museum and Art Gallery, where the delegates enjoyed the magnificent art collection and the pleasing habitat groups of birds and mammals under the guidance of Mr. S. C. Kaines Smith, the keeper, and Mr. Donald Payler, respectively. An unusually large trade exhibition was also staged in the Art Gallery.

Chemical Societies and Co-operation

IN his presidential address to the Society of Chemical Industry at Nottingham on July 13 under the title "Ourselves and Kindred Societies", Prof. G. T. Morgan discussed various aspects of the problem of re-union or co-operation among societies concerned with the furtherance of the professional and scientific welfare of chemists. The original territorial organisation of the Society of Chemical Industry in local sections holding their own meetings and other activities has in recent years been supplemented by the inception of subject groups, commencing with the Chemical Engineering Group in 1918.

Two such groups, the Food Group and the Plastics Group, have been formed during the past year, and this development alone is one which induces consideration of the relations of the Society with certain specialist societies and the possibility of such fusions or federations as was witnessed in 1882, when the Newcastle Chemical Society threw in its lot with the Society of Chemical Industry, and again this year, between the Food Group and the Society of the Food Industry.

An analysis of fourteen out of the sixteen separate societies concerned with the scientific and professional interests of chemists shows that the societies in 1930 had a total membership of 23,605 and a combined income from subscriptions of £46,557. Ignoring the fact that many individuals were members of several societies, the average annual subscription is thus about £2, the expenditure of which is divided as follows: 32·5 per cent for scientific literature, 6·5 per cent on social amenities, 6 per cent on library facilities, and 55 per cent on administration. This latter high proportion is attributed to the reluctance of chemists to assume such functions, and while paying tribute to the efficiency of administration of the societies generally, Prof. Morgan suggested that an important means of reducing this proportion of expenditure would be found in the societies drawing closer together and centralising or simplifying office appointments as losses from the staffs occurred through retirement, resignation, or other causes.

So far as the publication of scientific literature is concerned, the main burden is shared by the Chemical Society and the Society of Chemical Industry, and the formation of the Bureau of Chemical Abstracts already represents a measure of co-operation between the two Societies which, by eliminating duplication, adoption of a single format and index, etc., has enabled them to deal with the increasing volume of literature which requires abstracting. Attempts to organise an Anglo-American scheme have so far fallen through, but if the fourteen societies could collaborate in technical publication and pool their financial resources, there appears to be every prospect of the Bureau being able to deal effectively with the steadily increasing number of original memoirs in all branches of chemistry, unembarrassed by financial anxiety.

Following this step of co-operation in abstracting, Prof. Morgan suggested that the publication of joint in place of individual transactions would be a further economy. The steps recently taken by the Faraday Society and the Chemical Society for publishing ordinary contributions to the Faraday Society and physico-chemical papers of the Chemical Society as a new joint journal is an example that might well be followed. Similarly, the possibility of a joint chemical newspaper which would replace the more ephemeral part of *Chemistry and Industry* might also be well worth exploring. This journal would be able to present a wide survey of current topics of personal interest to English-speaking chemists, as well as including progress reports and summaries of scientific researches, and affording a suitable medium for the publication of the jubilee lectures or the lectures now arranged by the Institute of Chemistry on modern developments in the main branches of chemistry.

Improvement of library facilities, research facilities, and vocational education in chemistry are other matters that might be expected to follow the reunion or rationalisation of the profession. Effective action can, however, only be expected when, as Prof. Morgan pointed out, the members of the individual societies face the problem from the point of view of the well-being of the profession as a whole and not of the interests of an individual society.

Sunset Glows and the Andean Eruptions

ATTENTION was directed in NATURE of June 25, p. 932, to a report from Johannesburg of sunset afterglows in South Africa following the eruptions in the Andes last April. Two other correspondents have been kind enough to send further extracts from letters from the same place. Mr. A. Stanley Pye-Smith, 51 Wickham Road, Beckenham, Kent, sends the following extract from a letter dated May 3: "We are having very wonderful sunrises and sunsets, as a result of the volcanic dust from South America. The sky glows red long after the sun is visible, while there are no clouds at all to catch the light, as far as one can see. It is a pleasant change to have prolonged light in this latitude where darkness falls so quickly." Miss Cecilia F. O'Connor, 402 Milton Road, Cambridge, has sent extracts from a letter, dated May 4, received from her brother, Mr. E. R. O'Connor, Germiston, Transvaal, which give more precise details, stating that "at sunset the colours are magnificent, but it is about an hour later when they are best. Normally at that time it is pitch dark. But now the western sky is lit a flaming red light to the zenith—as though there were a huge volcano belching out volumes of fiery smoke. The red light is so powerful that everything catches a reflected tint, but yet you can see stars shining through, even to the west! What clouds there are, are etched in flame, and, towards the zenith, the red shades through purple to the ink blue of night." The same writer in a further letter, dated May 18, describes the sunsets as appearing to get finer, possibly because of the unsettled weather.

A letter, dated May 20, since received from Dr. E. Kidson, director of the Meteorological Office, Wellington, New Zealand, suggests that the volcanic dust had travelled on with the prevailing westerlies to New Zealand early in that month; it is probable therefore that the complete circuit of the southern temperate zone has long since been completed. Dr. Kidson describes the sunset afterglows that began about the end of the first week in May as very beautiful, ranging in colour from pale pink to yellowish pink in the western sky, the appearance showing a certain amount of structure suggestive of thin high smoke. Several reports of unusual manifestations of halo or corona have been received by his Department.

A particularly interesting point to which Dr. Kidson directs attention is that daily determinations of the intensity of the solar radiation at noon, made with the aid of an Ångström pyrheliometer, showed a sudden decrease of about ten per cent on May 5 and a slight recovery since. As an effect of this kind is likely to be general over the region affected by volcanic dust at high levels, it appears probable that the excess of solar radiation now being received by the earth's surface over the northern as compared with the southern hemisphere, on account of the season, is distinctly greater than usual. Although some effect on the weather is probable, it would be unsafe to refer abnormal weather at a particular place to this source, and there are not enough meteorological observatories at present to allow of a comparison between average weather conditions in the two hemispheres before and since the eruptions, in order to trace their effects.

E. V. N.

The Laboratory for Fresh Water Biological Research on Windermere

In Great Britain, research on fresh water biological problems has, for many years, suffered from the lack of adequate laboratory facilities—a curious fact since so much valuable pioneer work has been done in the British Isles, particularly on the lakes. The opening, last September, of a laboratory under the control of the Fresh Water Biological Association of the British Empire has removed this drawback, and investigators wishing to pursue the various branches of fresh water research can now be assured of obtaining the requisite facilities.

The laboratory is situated in Wray Castle, about three miles from Ambleside and on the north-west shore of Windermere. The lake reaches its maximum depth, just over seventy metres, about a quarter of a mile from the boat-house, and different types of inflowing streams and of shore lines are within a convenient distance. There is also a large number of streams and of smaller bodies of standing water within a short distance of the laboratory, these including examples of very diverse types, while almost the whole range of British fresh water habitats can be found within a distance of fifteen miles. There is thus abundant scope for biologists interested in plants or animals of special groups or in their habitat conditions.

The laboratory is equipped for most of the usual types of biological research. It contains ample facilities for microscopical and for experimental work, both purely physiological and also chemical. Gas for heating purposes is provided from a petrol-air installation. There is a large range of basement cellars which are used for aquaria or for storage purposes, while dark rooms are also available. The usual equipment for plankton investigation is provided, and for this and other forms of lake work a motor launch is available, as well as a smaller boat. This launch is a twenty-four-foot sea-going pinnace, fitted with gears so that very low speeds can be maintained for dredging operations. It also has a derrick and a winch driven by the motor for lifting heavy apparatus. The launch is provided with electric light and navigation lights for night work.

Persons working in the laboratory can obtain a variety of accommodation in Ambleside, and simple accommodation is available in the Castle itself, rooms having now been fitted up for this purpose. Inquiries about working places and research facilities may be made to the Naturalist-in-charge, Wray Castle, Ambleside, Westmoreland, or to the Honorary Director, Dr. W. H. Pearsall, The University, Leeds.

The Neutron

A group of three important papers on the production and properties of neutrons has appeared in the June number of the *Proceedings* of the Royal Society. The first, by J. Chadwick, is an account of his own experiments and a general discussion of the problems involved.

The experiments are in principle quite simple. Beryllium or boron is exposed to the α-particles of polonium, and the resulting penetrating radiation, probably a mixture of γ-rays with neutrons, examined with an electrical particle counter. The neutron has the property, otherwise only associated with radiation quanta, of being recorded by the secondary ionising action of some particle with which it has collided—in this case usually, if not invariably, the nucleus of an atom. Apart from the use of one of the new forms of electrical counters, the main point of the experiments seems to be that a very strong preparation of polonium is required.

Amongst the interesting questions which are touched upon in Dr. Chadwick's survey are the effective collision area which various nuclei offer to a neutron and the allied problem of the nature of the interaction. Dr. Chadwick finds by direct experiment that both for light and heavy nuclei the effective area is not much different from the usually quoted values for the size of the nucleus, and since experiments with lead indicate that neutrons are scattered about equally well in all directions, he suggests that the interaction may occur well inside the nucleus, which is in accord with the very limited region throughout which a neutron would be expected to have an appreciable field.

The other papers, by N. Feather and P. I. Dee, are concerned with the application of the Wilson cloud chamber to the problem. Dr. Feather has obtained a number of photographs of the collisions between neutrons and nitrogen nuclei, in which, on account of its negligible interaction with electrons, the neutron itself does not give a trail. The collisions appear to be of several types. In some, presumably elastic, there appears only the short, heavily ionised trail of the fast nitrogen nucleus which has been set in motion. The inelastic collisions were of two main types, in the first of which the neutron is captured and an α-particle liberated, whilst in the second the neutron is not captured but probably a proton liberated.

Mr. Dee's contribution is a search for visible evidence of the interaction of neutrons with the electrons of molecules in the air, using a most carefully adjusted Wilson chamber. This was not found, and the quantitative formulation of his results shows that the probability of interaction of a neutron with an electron, with the production of a recoil electron track, is less than one per cent of the probability of similar interaction with a nitrogen nucleus. The ionisation along the path of a neutron is given as less than one ion pair in three metres of air.

University and Educational Intelligence

Aberdeen.—The University Court has decided that in future the professor of surgery shall devote the greater part of his time to the duties of the chair, and that his private practice will be limited to cases seen and treated in Aberdeen—with rare exceptions. It is understood that preference will be given to those candidates of wide experience of clinical surgery and acknowledged power of teaching who, by their special training and record, have given evidence of their capacity for and interest in research. The appointment to the chair is made by the Crown on the recommendation of His Majesty's Secretary of State for Scotland.

THE following appointments have been made at Armstrong College, Newcastle: Dr. H. L. Riley to be professor of inorganic and physical chemistry; Prof. G. R. Clemo to be director of the Department of Chemistry.

A CHELSEA Polytechnic Old Students' Association is to be inaugurated at a meeting to be held on Nov. 4, on the occasion of the opening of the Polytechnic extension by the Parliamentary Secretary to the Board of Education, Mr. H. Ramsbotham, M.P. Old students wishing to be present at the meeting, or who desire particulars of the Association, should address communications to the Honorary Secretary, Chelsea Polytechnic Old Students' Association, Manresa Road, Chelsea, S.W.3.

DR. C. B. MARSON has been appointed head of the Chemistry Department of the Hull Municipal Technical College. Dr. Marson received his early training as an analytical chemist with Capt. J. A. Foster of Hull, and was for some time in the laboratories of the British Thomson-Houston Company at Rugby. After War service, he took a course in fuel and metallurgy at the University of Leeds, leading up to the B.Sc. degree, and for two years held the gas research fellowship of the Institution of Gas Engineers, working on the influence of inorganic constituents on the properties of coke. He was then appointed on the staff of the Joint Research Committee of the University of Leeds and the Institution of Gas Engineers, from which he proceeded to the position of chief chemist to the Northern Coke Research Committee.

SCHOOL buildings obviously condition the efficiency of school work just as factory buildings condition industrial efficiency in ways that admit of exact measurement, and the methods of investigation which the National Institute of Industrial Psychology has applied with notable success in the latter field are now being applied, on the initiative of the National Union of Teachers, in the former. The N.U.T. has issued a pamphlet containing a report, presented at a recent conference of local education authorities, on the progress of the enterprise. The problems dealt with include lighting, ventilation, heating, seating, staff rooms, workshops, playgrounds, cloakrooms, and blackboards, but the report is concerned chiefly with lighting. Exact measurements have demonstrated the supreme importance of good illumination, owing to its twofold influence in decreasing the time required for perception and in decreasing nervous and ocular strain, with consequent improvement in both quantity and quality of work. The value of window cleaning (so justly emphasised in a less enlightened age by that underrated educationist, Dr. Squeers) assumes a new importance when exhibited in graphs and percentages, and surprisingly good results are shown to be obtainable by attention to the amount of light reflected from furniture and walls. Some of the diagrams used are reproduced from "Seeing", by M. Luckeish, director of the Lighting Research Laboratory, Cleveland, U.S.A.

A SCIENTIFIC basis for national development was the aim of Senator Morrill, the promoter of the remarkable movement which, seventy years ago, brought into existence the 'land-grant' universities and colleges of the United States of America. In a summary—published as *Bulletin* No. 20, 1931, of the Office of Education, Washington—of an exhaustive report on these institutions, it is claimed that this aim has been achieved, and that they not only have added enormously to the nation's wealth, but also have helped to develop a new concept: government by science. By humanising scientific knowledge, they have, it is said, immeasurably improved the social life of millions of citizens who otherwise would tend to isolation from more favoured groups. The aggregate amount of their annual budgets exceeds one hundred million dollars, and their student enrolment exceeds three hundred thousand. Obviously they must have been and still are a potent factor in American culture, but as for the claim that they have achieved Morrill's object, this cannot easily be reconciled with Prof. John Dewey's contention in "Philosophy and Civilisation" (reviewed in NATURE of March 5) that the "disorder, confusion, and insecurity" characteristic of American social life are due to "our half-way and accidental use of science". In the same bulletin are summarised the results of another important national survey, that of negro colleges and universities, and a description is given of the purpose and organisation of three others now under way, those of secondary education, the education of teachers, and school finance.

Calendar of Geographical Exploration

July 24, 1862.—Central Australia

J. M. Stuart reached the coast of north Australia at the mouth of the Adelaide River near Port Darwin, thus achieving his aim of a land journey from south to north of the continent. Stuart's explorations began in 1858 in the country north of Lake Gairdner; in 1860 he discovered the Alberga and Finke Rivers and the MacDonnell range of mountains.

July 26, 1529.—Discovery of Peru

Francisco Pizarro was appointed governor of the newly discovered regions in Peru (New Castile). Pizarro had accompanied Balboa in the discovery of the Pacific and had there heard of the gold of Peru. In 1524 he had sailed from Panama and after three years of hardship reached the River San Juan. From that river one of his officers, Bartolomé Ruiz, set out in a small ship, crossed the equator, and sighted Peru. He brought back glowing reports of its gold and silver, and this led Pizarro to return to Spain to obtain help from the Emperor, Charles V. He started his return journey from San Lucar in 1530 and at the beginning of 1531 was *en route* for Cajamarca. By the end of 1533, Pizarro, like Cortes, sent out numerous exploring parties, the marches of which opened up much of the interior of South America.

July 27, 1767.—Discovery of Tahiti

Capt. Samuel Wallis left Tahiti (Otaheite), which he had discovered and where he made a long stay, sending an exploring party to the interior which reported on its great fertility. Various other small islands were discovered by Wallis on this voyage, which lasted from 1766 until 1768.

July 30, 1774.—South Russia and Siberia

P. S. Pallas returned to St. Petersburg after a journey which had lasted since June 21, 1768. He first investigated South Russia and the Caspian region. Later he wintered at Tobolsk, and then carried out researches into the morphology of the Altai Mountains and the region of the Upper Irtish. In 1772 he crossed Lake Baikal and explored the Upper Amur, and in the following year worked in the region of the Lower Volga. His observations helped to elucidate the problem of the origin of mountain ranges; he also collected much information about the natural history and economic conditions of the regions he studied.

Societies and Academies

LONDON

Mineralogical Society, June 7.—**J. E. Drugman** and **Max H. Hey**: Legrandite, a new zinc arsenate. A yellow transparent mineral on a single specimen of blende proved to be a new zinc arsenate. Chemical, optical, goniometric, and X-ray measurements were made, and the name legrandite is proposed for the new mineral, the formula of which is $Zn_{14}(AsO_4)_9OH.12H_2O$.—**W. F. P. McLintock**: The metamorphism produced by the combustion of hydrocarbons in the Tertiary sediments of south-west Persia. At various localities in south-west Persia, the escape and combustion of gas or oil have resulted in the brecciation, partial fusion, and crystallisation of calcareous marls with the formation of crystalline rocks consisting of pyroxene (diopside, ægirine-augite, and ægirine), wollastonite, pseudo-wollastonite, bytownite, melilite, and leucite, with glass, recrystallised calcite, and anhydrite. In the field, the rocks resemble vesicular igneous types, but microscopic examination and chemical analyses, accounts of which are given, prove them in all cases to be metamorphosed sediments.—**F. A. Bannister**: The determination of minerals in platinum concentrates from the Transvaal by X-ray methods (with chemical analyses and syntheses by **M. H. Hey**). X-ray rotation photographs have been used to distinguish and select for chemical analysis the various platinum- and palladium-bearing minerals present in the concentrates of Bushveld platinum ore. The name cooperite is retained for PtS, tetragonal, space-group D_{4h}^9. The face-centred unit cell with edges $a=4{\cdot}91$, $c=6{\cdot}10$ A., contains 4PtS. The atomic co-ordinates for platinum in this cell are $\frac{1}{4}\,\frac{1}{4}\,0$; $\frac{3}{4}\,\frac{3}{4}\,0$; $\frac{1}{4}\,\frac{3}{4}\,\frac{1}{2}$; $\frac{3}{4}\,\frac{1}{4}\,\frac{1}{2}$, and for sulphur: $0\,0\,\frac{1}{4}$; $0\,0\,\frac{3}{4}$; $\frac{1}{2}\,\frac{1}{2}\,\frac{1}{4}$; $\frac{1}{2}\,\frac{1}{2}\,\frac{3}{4}$. The structure is a simple type of fourfold co-ordination built up from plane PtS_4 groups and tetrahedral SPt_4 groups, the Pt-S distance being 2·32 A. Synthetic PtS has been prepared and is identical with the mineral cooperite. Laurite (RuS_2) occurs in small pyritohedral-cubic crystals and has the pyrite structure with unit-cell edge $a=5{\cdot}59$ A. The third mineral, $PtPdS_2$, containing about five per cent Ni, is also tetragonal with unit-cell edges $a=6{\cdot}37$, $c=6{\cdot}58$ A. The unit cell contains $4PtPdS_2$ and the space group is D_{4h}^1. The name braggite is proposed for this mineral as being the first discovered by X-ray methods.—**John Parry, Alpheus F. Williams**, and **F. E. Wright**: Bultfonteinite, a new fluorine-bearing hydrous calcium silicate from South Africa. This new mineral was found in the Bultfontein and Dutoitspan diamond mines at Kimberley and in the Jagersfontein mine in Orange River Colony. It forms pale pink globular aggregates of radiating needles, and has much the appearance of natrolite. Analysis gives the formula $2Ca(OH,F)_2.SiO_2$. From the manner in which the mineral is decomposed by water and by dilute acids, a formula written as $Ca(OH)_2SiO_2.Ca(OH,F)_2$ is suggested. Goniometric and optical examination of the minute crystals shows them to be triclinic, but much complicated by polysynthetic twinning. The mineral is related to afwillite with the addition of $Ca(OH)_2$ and CaF_2, and the nearest ally is custerite $[CaO.Ca(OH,F)_2,SiO_2]$.

Geological Society, June 16.—**L. R. Wager**: Geological work in East Greenland during the British Arctic Air-Route Expedition, 1930–31. The winter base of the expedition was in the Angmagsalik district and most of the geological work was carried out there and also in the course of two journeys. The first journey was northwards for 300 miles along the coast to Kangerdlugsuak, and the second along the edge of the ice-cap to Mount Forel. The Angmagsalik district consists of gneisses and schists for which the name Metamorphic Complex is used, since the Archæan age of these rocks cannot be proved. The coastal zone between the ice-cap and the sea north of Angmagsalik consists of high mountains and includes Mount Forel, the highest mountain within the arctic. These mountains have been cut from a raised peneplain which passes without interruption from the Metamorphic Complex to the Tertiary basalts and plutonic intrusions. The peneplain has a gentle dip to the south-east or east-south-east, and to this is due the general trend of the coast and of one group of valleys and fjords. The inland ice has recently receded, and its present action may be studied side by side with its effects on the recently uncovered mountainous surface.

Physical Society, July 8.—**J. J. Manley**: On the determination of refractivity temperature coefficients for liquids. Attention is directed chiefly to the problems of measuring with precision the changes in the refractivity of a liquid for small alterations in temperature. An elaborated Jamin interferometer is described, with auxiliary apparatus necessary for setting up and maintaining differences in the temperature of the two interferometer tubes. Further, there is given a plan for measuring by means of platinum resistance thermometers differences in the temperatures of the two tubes.—**N. W. McLachlan**: (1) The axial sound-pressure due to diaphragms with nodal lines. A formula is found for the axial sound-pressure due to a disc having a nodal circle, and vibrating in an infinite rigid plane. Beyond a certain axial distance, when the nodal circle occurs at $r=a/\sqrt{2}$ the pressure vanishes owing to interference caused by the inner and outer portions of the disc vibrating in opposite phase. The case of n nodal circles of arbitrary radii is treated by an approximate method. A rigid disc is imagined to be severed around each nodal circle, whilst contiguous annuli vibrate with equal amplitudes in opposite phase. Finally the pressure on the axis of a conical shell having nodal circles is treated as in the previous case. When the semi-apical angle of the cone is $\frac{1}{2}\pi$ and there are no nodal circles, the formula reduces to that for a rigid disc.—(2) The accession to inertia of flexible discs vibrating in a fluid. Formulæ are obtained for the velocity-potential at the surface of a free-edge disc vibrating with nodal lines in a fluid. These formulæ are used to ascertain the accession to inertia due to the fluid when the disc is set in an infinite rigid plane. The equivalent mass and the mass coefficient of the disc vibrating *in vacuo* are also found; and the influence of the fluid on the frequency of vibration with (*a*) one nodal circle, (*b*) one nodal diameter, (*c*) stationary centre, is evaluated.—**A. J. Bradley** and **A. H. Jay**: A method for deducing accurate values of the lattice spacing from X-ray powder photographs taken by the Debye-Scherrer method. The usual circular type of camera is employed; and there are two stages in the procedure, (*a*) the calibration process, (*b*) the extrapolation process.—**G. Millington**: Ionisation charts of the upper atmosphere. Prof. Chapman's theory of the ionisation of the upper atmosphere by solar radiation has been applied to construct a set of charts giving contour lines of equal ionic density over the surface of the earth. A simple approximate method of solving the fundamental differential equation of the theory by a rapid arithmetical process is described.—**A. S. Rao**: Further investigations of the arc spectrum of arsenic. By photographing the spectrum of arsenic by the method of the hollow cathode discharge in helium and in neon about a hundred new lines have been recorded. The analysis of As I published by previous investigators has been considerably altered

and extended. New levels have been added and the higher members of the chief groups of the series of *ms* terms have been identified. A mean value of 85,000 cm.$^{-1}$ has been suggested for the deepest term $4p\ ^4S_2$ which leads to a first ionisation potential of approximately 10·5 volts for arsenic.

EDINBURGH

Royal Society of Edinburgh, June 6.—**L. M. Davies**: The genera *Dictyoconoides* Nuttall, *Lockhartia* nov., and *Rotalia* Lamarck. The original types of Carter's *Dictyoconoides* [*Conulites*] *cooki*, which have recently been found after having been lost for nearly thirty years, are described and figured; also the original types of Lamarck's *Rotalia trochidiformis*, from the Defrance collection at Caen. The characters and relationships of these species are discussed; and a certain number of other species, hitherto referred to *Dictyoconoides*, are removed to a new genus *Lockhartia*.—**E. B. Bailey** and **J. Weir**: Submarine faulting of Kimmeridgian date. During Kimmeridgian times a submarine fault scarp was maintained by intermittent movement of the sea floor of the Helmsdale district of East Sutherland. Unconsolidated Mesozoic rocks on the upthrow side of the fault dissipated without yielding boulders, but Old Red Sandstone exposed in the fault scarp furnished repeated landslips, carrying boulders that in exceptional cases measured 100 feet in length. Earthquakes were frequent, for the landslips are almost always spread out into graded boulder beds in a manner indicating co-operation of tunamis ('tidal waves'). The Helmsdale movement can be brought into relation with the general history of contemporary Britain, more particularly with the fissuring of Kimmeridgian at Ethie on the Moray Firth and the development of the Camasunary fault in Skye.—**T. Johnson**: The Tertiary plants of Ireland and Scotland: a comparative account—(1) Thallophyta to Gymnospermæ. The paper deals with collections of fossil plants from the north-east of Ireland, including those found at various depths (780-930 ft.) in the core of a bore made at Washing Bay at the south-west corner of Lough Neagh, and with collections of more or less contemporaneous plants from the Hebrides, including a small collection from the Isle of Canna and another from a site discovered by Mr. I. A. Inglis in the Isle of Skye.—**Mary H. Latham**: Scottish Carboniferous Ostracoda. The specimens come from one hundred and forty different localities in the Carboniferous of Scotland and England. Most of the species appear to have quite a long range, few of them being restricted to one horizon, although some occur only in the Upper Limestone Series of the Scottish Carboniferous and others are confined to the Lower Limestone Series.—**Ian M. Robertson**: A study of the tyrosinase of potato tubers. With *p*-cresol as substrate, the tyrosinase present in potato tubers produces a bright orange-red colour. The kinetics of the reaction have been studied by treating tuber sections with aqueous solutions of *p*-cresol in caustic soda and measuring the colour changes by means of Lovibond colour standards. The course of the reaction is monomolecular, with initial and final linear periods. The activity of the enzyme is independent of such factors as soil and environmental conditions of growth, season, and storage, but is dependent upon tuber maturity, disease, and variety. The test has been applied successfully towards the determination of the variety of healthy, mature tubers.

PARIS

Academy of Sciences (vol. 194, pp. 1993-2092), June 6.—**G. Urbain**: An attempt at a co-ordinative theory of the constitution of organic compounds.—**C. Camichel, P. Dupin**, and **M. Teissié-Solier**: The non-turbulent regime beyond the criterion of alternate vortices.—**Lucien Daniel**: New researches on the descent of certain grafted Compositæ.—**Ehresmann**: The integral invariants and the topology of ruled projective space.—**D. V. Jonesco**: Certain curves which generalise conics.—**Rud. Fueter**: Hermite forms, Picard group, and the theory of quaternion ideals.—**M. Ghermanesco**: The problem of Riquier.—**Arnaud Denjoy**: The characteristics of the torus.—**Alex. Froda**: The vertical measurability of functions of real variables.—**J. Le Roux**: The differential invariants of groups of relativity.—**J. Haag**: The general theory of the elastic suspension of pendulums.—**G. Siadbei**: The measurement of the resistance opposed by a viscous medium to the movement of bodies.—**J. Rossignol**: The problem concerning cylindrical vortices of finite section.—**André Douillet**: An apparatus with elastic coupling for measuring and recording graphically rotation couples.—**Émile Belot**: The original and present orientation of the orbits of the minor planets and of Jupiter in relation with the causes of the primitive eccentricities.—**D. Eginitis**: An error of Posidonius and its influence on the discovery of America.—**L. Néel**: The magnetic susceptibility of sulphur vapour. The diatomic molecule of sulphur is paramagnetic, and its properties are clearly different from those given by the theory applicable to oxygen.—**J. Lecomte**: An attempt at the co-ordination of the infra-red absorption bands of some hydrocarbons with nucleus.—**Maurice Curie** and **Jean Saddy**: Phosphorescent sulphides. Extinguishing action of the metals of the iron group. Traces of cobalt or iron reduce or prevent the phosphorescence of zinc sulphide. Lead is without influence.—**Marcel Cau**: The interpretation of a magneto-optical effect.—**Jacques de Lassus Saint-Genies**: A partial solution of integral photography.—**W. Broniewski** and **K. Wesolowski**: The gold-silver alloys as a type of continuous solid solutions. A study of 15 physical properties of gold-silver alloys as a function of the composition of the alloy. The results are given graphically.—**A. Michel-Lévy** and **H. Muraour**: Certain substances modifying the double refraction of the nitrocelluloses.—**F. Bourion** and **Mlle. O. Hun**: The cryoscopic study of ether and acetone in solutions of potassium chloride.—**Desmaroux** and **Mathieu**: Remarks on the structure of films of nitrocellulose with high nitrogen content.—**Paul Renaud**: A mineral india-rubber. Phosphorus chloronitrides of the constitution $(PNCl_2)_n$ on heating in sealed tubes to 270° C. polymerise, giving rise to substances possessing some of the properties of india-rubber.—**G. Darzens** and **André Lévy**: A new synthesis of eudaline (methylisopropylnaphthalene).—**A. Hodaghian** and **R. Levaillant**: The action of lithium hydride on benzoyl chloride. The main primary product is probably benzaldehyde, but this is polymerised, giving benzyl benzoate as the main product.—**Marcel Godchot** and **Max Mousseron**: 2-Aminocyclopentanol and its resolution into its optical antipodes.—**Lucien Semichon** and **Michel Flanzy**: The application of chromic acid oxidation to some diacids.—**L. Palfray, S. Sabetay**, and **Mlle. Denise Sontag**: α-Vinylnaphthalene and the polyvinylnaphthalenic resins.—**Charles Dufraisse** and **Robert Vieillefosse**: The application of the anti-oxygen effect to the problem of fighting fire. The extinction of charcoal in the presence of oxygen. The vapours of carbon tetrachloride or phosphorus oxychloride have a real anti-oxygen effect on burning charcoal.—**Georges Laude**: The synthesis of cyanic acid and of urea by the ammoniacal oxidation of carbonaceous substances. A modification of the methods previously described, giving higher yields of urea and cyanic acid.—**R. Bureau**: Goniometric

researches on atmospherics.—**Pierre Gavaudan**: The identity of the metachromatic vacuome and of the leucosine of the Monadineæ and Chrysomonadineæ.—**A. Damiens** and **Mlle. S. Blaignan**: Normal bromine in plants: edible plants and fruits. Bromine is a normal constituent of plants, the amount in 100 grams of dry material varying between 0·17 and 2·02 mgm. The amount in the fruits is less.—**Ph. Joyet-Lavergne**: The rôle of the chondriome in the manifestations of cytoplasmic sexualisation.—**A. Magnan** and **A. Sainte-Laguë**: Flight by wing beats at a fixed point.—**Philippe Fabre**: The exciting efficacy of condenser discharges below the rheobase.—**Mme. Phisalix**: The reciprocal vaccinating action of the poisons of the bee and *Vipera aspis*.—**R. Legroux**, **Kemal-Djemil**, and **Mme. Colette Jéramec**: The immunisation of guinea-pigs against glanders.—**J. Lignières**: Paradoxical phenomena of the immunising property of the aphthous virus. A local aphthous lesion does not always confer immunity.

Economic Problems of Native Communities

THE East African group of British colonies and dependencies has, during the last few years, had to endure a series of Government commissions, all undertaken with great pains and conducted by able chairmen. One of their main objects has been to determine the course of the political evolution of these regions, and the net results have been alternately to excite and depress the political aspirations of the resident European and Asiatic community, but the reflex effect on the more sophisticated section of the overwhelming black population cannot have been to its advantage.

The commissions culminated in a prolonged inquiry carried out by a Joint Committee of both Houses of Parliament sitting in London and presided over by the late Lord Stanley of Alderley, and after his lamented death, by Lord Onslow. This was a momentous business; it went on for some months and issued a monumental and well-balanced report. But inquiry was not yet to cease, for arising out of this Joint Committee is the report by Lord Moyne which is now before us; * one on railway economics, one on the financial position of Tanganyika Territory, and the Morris-Carter Land Commission are yet to come as sequelæ of the Joint Committee.

After the considerable expenditure of public funds involved by these extensive inquiries, it was pleasing to hear the Secretary of State for the Colonies recently declare, at the annual East African dinner, that inquiry had been overdone and would henceforth cease. Lord Moyne's report is, however, an admirable document; it is short, and it goes to the heart of things, namely, the economic position of the Colony. The old country, the heart of reserves of centuries of capital accumulation, has been shaken to its foundations during the last two years; the marvel therefore is that the colonies, all dependent on the production of raw materials which have slumped below cost of production, can have survived at all.

The main objects of Lord Moyne's inquiry were to ascertain the contribution made to taxation by the different racial communities, to review railway freights and import duties, and thus discover the extent to which each community in the colony benefits or suffers. Further, to ascertain as nearly as possible the amount of public money expended on natives and non-natives, and to what extent financial responsibility should be conferred on

* Report by the Financial Commissioner (Lord Moyne) on Certain Questions in Kenya. (Cmd. 4093.) Pp. vi+122. (London: H.M. Stationery Office, 1932.) 2s.

Native Councils. Lastly, to consider the general and economic situation in Kenya.

Lord Moyne approached his inquiry in an unbiased fashion, and conducted his mission with great rapidity; he has produced a document which it is impossible to controvert, and which should do much to dissipate a cloud of misinformation which has of late tended to obscure the situation.

Lord Moyne deals in detail with the incidence of the Hut and Poll Tax, which has up to now been the somewhat rough-and-ready way by which the native population of the country has made its contribution to the revenue. He puts his finger on the weak points of this system, and demonstrates how increasingly difficult it has become, particularly in some of the more remote districts, for natives to obtain the cash since the great slump in the values of produce occurred. He goes on to demonstrate how this fall in values has crippled the purchasing power of the natives, and so trade, generally, has greatly declined. The inequality, the inelasticity of this form of taxation, its lack of relation to prices of raw material, produced a considerable impression upon his financial mind, and he, moreover, pertinently remarks that "natives pay their tax not out of a fixed income but by means of additional production in the Reserves or alternately they may choose to earn the money by work in settled areas". For these reserves Lord Moyne recommends that the hut tax should eventually be replaced by a cultivation tax, that the poll tax should be a fixed sum, and in addition, there should be a live stock tax. There is much to be said for these proposals, but he does not appear to have considered fully the great increase of fiscal machinery these changes will involve when dealing with vast numbers of small cultivated plots. He next analyses the railway rates policy, and comes to the conclusion that their incidence is generally fair as between the racial communities. The same conclusion is also arrived at with regard to the incidence of import duties.

Perhaps the most difficult part of Lord Moyne's survey was the attempt to assess the amount of money expended in the interests of each community; and the impossibility of carrying out this aim with a great degree of accuracy is freely acknowledged. It is pointed out that the costs of various services, such as, for example, military and police, must be shown under general heads, for they benefit all communities. The plan of making two arbitrary divisions was thus adopted, namely, divisible and indivisible services. Even when this has been done, contrasts between racial standards of life make the measure of equality of sacrifice in taxation even more difficult of assessment. Lord Moyne frankly admits that he has formed the opinion that "in the development of the undivided services in Kenya there has been a bias towards the conveniences of a civilisation in which the native so far shares little of the direct advantages". But he goes on to make it clear that there is no suggestion that the European community has taken unfair advantage of their opportunity; it was, however, only to be expected when on one side we find a well-organised, politically-minded body of Europeans and on the other a mass of Africans only faintly articulate and with a weak representation on the Legislative Council. But after considering every factor in the case, as Lord Moyne realises, it is not even then easy to assess a fair proportion of expenditure for each section.

In 1931 each European contributed nearly £29 to the revenue of the Colony and each native contributed 5 shillings; the individual gap is immense. The aggregate contributed by some 17,285 Europeans is £665,780 and that contributed by some 2,950,000 natives is £791,100, and the amount spent directly on the European community is about £171,250 and on the African £332,000. The difficulty of comparison is due to the fact that the bare standard of service necessary for Europeans can bear little relation to that necessary for Africans.

The greatest problem at present in all African countries is to raise the culture level of the native; it was rising slowly up to the occurrence of the world-wide depression, and was mainly due to the progress of the activities resultant on white settlement; and when prices rally this progress will be resumed. A rise in the culture stage of the native, however, cannot be delayed, and it is essential to educate him to the widest extent in the practical art of life, so that he may obtain a better yield from his land and conserve and improve its agricultural value, instead of ruining it as he is doing at present. If this can be achieved, we shall fully justify our presence in Africa. At the same time, with the progress of the prosperity of the village the native cannot fail to develop sociologically. The African to-day is avid for education, but too often confines himself to a desire to read and write.

In order to ensure a definite provision for steady progress in education, agricultural training, and medical hygiene, we find the recommendation that one-half of the revenue obtained from native direct taxation should be placed each year in what is termed a Native Betterment Fund, to be adminis-

tered by a special committee, with which natives are to be closely associated, and also representatives of the European colonists. This, if carried into effect, is a proposal which will be welcomed by native opinion and do much to demonstrate the solicitude of Government to give the natives a fair deal. The Kenya politicians may, however, plead that it is unconstitutional, as it will operate independently of the Legislative Council.

The proposal to found a Native Marketing Advisory Council is also one that is long overdue, for the victimisation of natives by Asiatic traders has for years past been a matter of concern.

Space forbids reference to many points of interest, but it is evident that, quite apart from its special reference to one Colony, Lord Moyne's report carries many lessons which are applicable to other dependencies of a similar class, for it demonstrates the importance of far-sighted discrimination in regard to local financial demands, and the necessity of firmer control than that which successive governors have, owing to political exigencies, been able to exercise in the past. C. W. H.

Recovery: A Scientific Programme

Recovery: the Second Effort. By Sir Arthur Salter. Pp. xvi + 306. (London: G. Bell and Sons, Ltd., 1932.) 10*s.* 6*d.* net.

THERE could be few more startling contrasts than that between the pedantic platitudes of the naval and military experts of the Disarmament Conference, their endless splitting of hairs, and the balanced and comprehensive survey of the events during the last thirteen years that have been mainly responsible for the present critical world position which Sir Arthur Salter gives us in his book "Recovery". Alike in his analysis and summing up of the various special problems of currency, finance, reparations and war debts, tariffs, industrial organisation, Government control and security, on which his experience as a high official of the League of Nations, as first general secretary to the Reparations Commission, and active participant in most of the international negotiations and acts in the first effort at post-war recovery render him an expert authority of the highest standing, Sir Arthur writes with a vision and a sense of values which only emphasises the narrow-mindedness and inadequacy of the military and naval experts. We have been accustomed in Britain to admit such experts to positions of high administration and authority from which the scientific expert is rigidly excluded. When allowance has been made for Government pressure or for the absence of adequate instruction or definite policy from the Conference itself, the proceedings of the experts at the Disarmament Conference make a dismal record which may well endanger the future use of the expert in administration, in spite of the striking success which under appropriate conditions has attended the work of the expert committees of the League in health, finance, economics, transit and communications, etc.

The masterly diagnosis which Sir Arthur gives us of the causes of the world depression conveys the emphatic impression that the main cause of our present critical position is not monetary, economic, or political, but the persistent attempt to handle world problems on national and sectional lines—the same effort which, unless public opinion realises the danger in time, threatens to defeat the purpose of the Disarmament Conference. The whole book is an antidote to such small-mindedness. Writing with an essentially scientific outlook, Sir Arthur conveys not only a sense of perspective in viewing the complex reactions of the financial, industrial, economic, and political factors involved in the field of monetary policy, credit, commercial policy, economic organisation, government, and peace, but also gives us trenchant and constructive criticism which leads him to prescriptions for recovery and for a 'New World Order' set out in his concluding chapter.

To this chapter the majority of readers will turn most eagerly, and it should accordingly be noted that Sir Arthur reaches his conclusions as a result of impartial analysis of the relevant factors and a determined attempt to disentangle them from prejudice. Only in this way can we arrive at a satisfactory basis for adequate action, and this method of procedure will at once be recognised as fundamentally that of science.

Characteristic of the book is its note of confidence. Difficult as is our task, the problem facing us is, as Sir Arthur rightly reminds us, capable of human solution. "Never was Nature so prodigal in her gifts; never was man so well equipped in skill and scientific resources to utilise them." Or again, "We are, if we could but grapple with our fate, the most fortunate of the generations of men. In a single lifetime science has given us more power over Nature, and extended further the range of vision of the exploring mind, than in all recorded history. Now, and now only, our material resources, technical knowledge, and industrial skill are enough to afford to every man of the world's teeming population comfort, adequate

leisure, and access to everything in our rich heritage of civilisation that he has the personal quality to enjoy." This is the spirit in which the triumphs of science and of statesmanship alike have been achieved, and the book was worth reading if only for the reminder it gives us that by bringing to our task courage and magnanimity we shall assuredly find the wisdom to control our specialised activities and the waywardness of our sectional and selfish interests. The difficulties and problems created by defects in human organisation, planning, and direction, or from weakness in our financial and distributive systems, are essentially remediable evils and removable causes, requiring only for their elimination an effort of searching analysis and constructive reform in our western world comparable in boldness and determination with that which is now being witnessed in Russia, with however different a goal or method.

It is in this spirit that Sir Arthur is led to his constructive proposals. Accordingly, he sees the need for central institutions to put the credit and borrowing capacity of selected classes of those needing capital on the soundest foundation. Such institutions would be able to secure, far more economically and efficiently, the necessary experts to examine the technical merits of any proposed scheme. Suitable mechanism is also required to secure that any political factors involved should be examined by some agency of the League of Nations, to prevent any repetition of the discreditable borrowings of 1926–28, with their dangers to world peace.

Discussing commercial policy and tariffs, Sir Arthur Salter points out the fallacy of most of the so-called scientific tariffs and the way in which they tend to direct energy and attention from the improvement of industrial efficiency to the corruption of governments. The only scientific tariff, in Sir Arthur's view, is that offered temporarily and conditionally by a strong and competent government to stimulate and assist reorganisation of an industry. This authoritative comment indicates the wisdom of the policy advocated by Capt. Macmillan in regard to the functions of the Tariff Commission, and is an emphatic warning of the dangers attending the unregulated introduction of a tariff system. The dislocation and gradual stoppage of international trade is a danger to the world second only to the menace of world peace which the consequent disintegration into separate units and groups presents.

Part of the support for a tariff policy in Britain has come from those who recognise the need for a more deliberate and collective planning of our economic life; and the existence of such support, which is likely to be conditional on an increasingly better planning for real public and social benefit, constitutes some hope of reform. For similar reasons, Sir Arthur, while frankly recognising certain dangers inherent in the growth of large industrial organisations, sees in them the means of securing the necessary planning of supply over the whole range of an industry, and so securing stabilisation as no national agreement could do except behind prohibitive tariffs. International agreements and cartels and National Economic Councils can in fact constitute a basis upon which a World Economic Council could effectively discuss, upon a world range, questions of finance and control of output, resulting in definite industrial planning through the world, and in addition, by cutting across national frontiers, they create interests and forces which will tend to counteract the competitive nationalism which is the world's chief danger.

These National Economic Councils are themselves a significant development of the last decade, and although at present largely experimental, may ultimately prove of great value in the machinery of government, which almost everywhere is now proving inadequate to the tasks which it has assumed. Sir Arthur's natural sympathy with *laissez faire* emphasises the policy of economic planning and radical reconstruction to which he is driven by facts and not by inclination. Only by such a policy can he see the mechanism of central direction and restraint sufficiently strengthened to control the specialised activities of men and the individual energy whether of persons or organised sections which threatens to destroy and not extend the common weal. Delegation of national government authority along such lines, drawing into the public service the great private institutions which represent the organised activities of the country, including chambers of commerce, banking institutions, industrial, professional, and labour organisations, and simultaneously the integration of the national organisation thus developed into an organ of world policy through the League of Nations, is the way in which Sir Arthur visualises government as becoming once more equal to its task. The whole framework, first and last, is based upon peace, upon the firm establishment of the collective system in the confidence of the world, until in the new world order the causes from which wars originate are eliminated.

Here is a programme worthy of earnest consideration by scientific workers individually and

through their professional and industrial organisations. Sir Arthur Salter has given us as it were a world map on which the broad lines of advance, the practical routes, are plainly marked. The details have yet to be filled in if mankind is to advance towards recovery, and that advance depends not more on the contribution of statesmen than of scientific workers and other individual sections of the community. To that task of systematic and scientific exploration each must bring their contribution in a spirit of adventure, of courage, of magnanimity which, for the moment, so many in this apprehensive world seem to have abandoned.

Some Extinct Horned Mammals

Department of the Interior : U.S. Geological Survey. Monograph 55 : The Titanotheres of Ancient Wyoming, Dakota and Nebraska. By Henry Fairfield Osborn. Vol. 1. Pp. xxiv + 701 + plates 1-42. Vol. 2. Pp. xi + 703-953 + plates 43-236. (Washington, D.C.: Government Printing Office, 1929.) 9 dollars.

THE Titanotheres are a group of odd-toed hoofed mammals which lived during the early part of the Tertiary epoch about the fortieth parallel of latitude in North America and Asia, and occasionally strayed into eastern Europe. They are peculiar in their low-crowned molar teeth, which never became sufficiently deepened to be useful for feeding on dry vegetation. They are also unique among odd-toed hoofed mammals in having the forefoot almost like that of the even-toed hippopotamus, with only a slight tendency towards the greatest weight on the third toe. So far as known, they first appeared at the end of the Lower Eocene period, when they were small hornless dwellers in swamps, evidently feeding on succulent vegetation. They became extinct at the end of the Lower Oligocene period, when most of them had grown to be as large as rhinoceroses or even as small elephants, adapted to live on hard ground, with prehensile lips for browsing, and with a pair of horns, supported by bony cores, on the top of the prominent nose. The fossil remains of these large forms were found first, and hence the name given to the group.

As the Titanotheres completed their evolution in so short a period of geological time, and as they are now represented in museums by the remains of very numerous individuals of many genera and species, they are of extreme interest to the palæontologist. They are also of value to the geologist as marking successive layers in the early Tertiary rocks where they happen to occur. Science is therefore much indebted to the United States Geological Survey and to Prof. Osborn for the two handsome volumes in which these extinct mammals are most exhaustively described and discussed from every point of view. The monograph was planned many years ago by the late Prof. O. C. Marsh, who supervised the drawing of numerous plates which are now reproduced and used as effective illustrations. Prof. Osborn, with the aid of his colleagues in the American Museum of Natural History, has been engaged on it since the beginning of the year 1900. The result is the most elaborate work ever devoted to a group of vertebrate fossils.

All the known genera and species are described in detail in systematic order, with full references to the literature of the subject, and beautiful drawings and outline sketches of the fossils on which they are founded. The systematic descriptions are then supplemented by a valuable chapter on the probable muscular anatomy of the Titanotheres by Prof. W. K. Gregory, who also discusses the mechanics of locomotion both in these mammals and in the other odd-toed families. The central feature of the monograph, therefore, is a well-arranged collection of facts, which will always remain available for reference, however much opinions may differ as to their interpretation.

Nearly half of the monograph is devoted to general questions and the interpretation of the facts, which have already been dealt with by Prof. Osborn in preliminary papers during the progress of the work. These chapters are a little difficult to appreciate, on account of the literary style, frequent repetitions, and lack of conciseness; but they bring together a remarkable mass of material for which both geologists and palæontologists will be grateful. The numerous diagrammatic illustrations are especially helpful.

One preliminary chapter gives an elaborate account of the various American Eocene and Oligocene formations in which remains of Titanotheres occur, and concludes with a series of photographs of localities in which collections have been made. Another chapter discusses mammalian palæontology in general. Other chapters deal with various aspects of the evolution of the Titanotheres and their allies, and the possible ways in which they may have been exterminated at the time when they attained their maximum development and apparently maximum strength. It is especially interesting to notice that there seem to

have been several parallel groups all evolving in the same direction but at different rates—a phenomenon which is now becoming familiar to those who trace the distribution of extinct animals through successive geological formations.

When the monograph had been completed, the exploring party of the American Museum of Natural History in Mongolia made the first great collection of remains of Titanotheres from Asia. Prof. Osborn has therefore added a very interesting appendix on this discovery. It appears that most of the genera found in Asia are identical with those already recognised in North America, but they are represented by species which are about twice as large as those already met with in America. There is also a new genus, *Embolotherium*, comprising some of the largest Titanotheres known, in which the two immense horns are fused into a battering-ram. This animal was one of the latest members of the race, existing at the end of Lower Oligocene time; and when it became extinct, its place was taken in the Gobi region by the gigantic *Baluchitherium*, which belonged to the rhinoceros group.

Prof. Osborn's stimulating monograph, indeed, leads us to hope that it is only the first of a series which the United States Geological Survey will publish, when other groups of American fossil vertebrates have been studied in equal detail from our present point of view. A. S. W.

Domestic Science

(1) *Everyday Domestic Science and Hygiene.* By I. C. Joslin and P. M. Taylor. Pp. viii + 532. (London: Macmillan and Co., Ltd., 1932.) 6*s.*; Part 1, 3*s.*: Part 2, 3*s.* 6*d.*

(2) *Household Physics.* By Walter G. Whitman. (The Wiley Technical Series for Vocational and Industrial Schools.) Second edition, revised. Pp. vii + 502. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1932.) 16*s.* 6*d.* net.

(1) THE first of these books has been written with the object of providing a scientific foundation for a school course in household science and human physiology up to the standard of the General Schools Examination. The general plan of the book is excellent. The elements of physics and chemistry are first dealt with, and the pupils' interest in the subject is well maintained both by the experimental work and by the numerous examples showing the application of the principles to domestic work. A knowledge of food values is essential for the proper planning of meals, and the authors have shown their appreciation of this fact by their very thorough treatment of this section of the subject. The source, preparation, and methods of cooking of the chief substances used as foods are described and many experiments are given. A chapter on micro-organisms well emphasises the necessity for cleanliness in the preparation and storage of foods—a subject which in Great Britain has, up to the present time, received far too little attention. Human physiology, personal hygiene, and first-aid are treated so far as "they may be studied appropriately in a general science course for girls".

The authors do not give any indication of either the number of periods a week or the number of years required to complete the course satisfactorily. An examination of the book would indicate that three periods a week, one devoted to practical work and two to class work, for three years, would enable the work to be done in such a way as to secure the maximum value in educational training and a good knowledge of the subject. The book is one of the best dealing with this subject that has appeared in recent years; the sequence of practical work and class work is excellent, and the most recent developments are included. Among such may be mentioned the 'Regulo' device for controlling the temperature of the modern gas oven, the principles underlying the working of the household refrigerator, and the importance of vitamins in foods.

(2) The second of these books aims at presenting physics adapted for girls both in general and in home economics courses. The method is almost entirely instructional as distinct from educational, and every device used in the home, from electric lamps to 'talking picture' projection, and from carpet sweepers to twelve-cylinder motor cars, that depends in any way upon physics, is fully described. Most of the subjects are treated in far too great detail; for example, it is not necessary, for an intelligent understanding of the working of electric home appliances, to have a knowledge of magnetic fields around a solenoid or of the principles underlying the use of 'step-up' transformers. It is difficult to justify the inclusion of descriptions of such instruments as compound microscopes in a household physics course. The illustrations are numerous and excellent, and the subject matter is dealt with in a very interesting way. The book is one that would appeal to all mechanically minded boys, and would be a welcome addition to any boys' school library.

It will be noticed that though both the books have about the same number and size of pages and are equally well produced, the price of the first is 6*s.* and of the second 16*s.* 6*d.* J. H. S.

Short Reviews

(1) *Fortschritte der Biochemie.* Teil 2 (1924–1931). Von Prof. Dr. Felix Haurowitz. (Wissenschaftliche Forschungsberichte, Naturwissenschaftliche Reihe, herausgegeben von Dr. Raphael Ed. Liesegang, Band 26.) Pp. x + 152. (Dresden und Leipzig: Theodor Steinkopff, 1932.) 11 gold marks.

(2) *Les problèmes de la biochimie moderne.* Par Prof. G. Florence et Dr. J. Enselme. Pp. 312. (Paris: G. Doin et Cie, 1932.) 45 francs.

(1) THIS small book is a comprehensive review of biochemical literature during the period 1924–1931; it is a continuation of Part I. (1914–1924). An index mentions 900 authors, and more than one thousand papers must have been referred to, so that little of importance has escaped. The size of the book has imposed considerable brevity (wave mechanics are treated in a single page); hence it is scarcely a continuation of older textbooks, as the preface seems to suggest, but rather a valuable guide to the recent literature, which every biochemist should possess. There is even a useful final section on methods. Robinson on p. 14 should be Robison, and on p. 28 we are referred to a formula on p. 00 which does not seem to have been included anywhere.

(2) The title suggests a resemblance to the preceding, but a study of the contents reveals considerable differences. The French authors include older work and often little that is recent. Thus the section on muscle metabolism does not extend beyond 1928, and seems actually based on the junior author's M.D. thesis of 1924; it is consequently completely out of date. The sections on hæmin and chlorophyll are likewise antiquated. The range is smaller than that of the German book, and even those topics which have been selected are often treated inadequately, for example, the sterols. The section on carbohydrates is among the more satisfactory. Sometimes there is considerable detail; thus the (old) method of preparing glutathion (still a dipeptide) is described at great length, and the mathematical theory of Svedberg's ultracentrifuge is included, so that the book has its occasional uses. It is marred by numerous misprints. There is not only disregard for the spelling of proper names (Lotter-Maser; Deloye and Scherrer in the text, Debye and Sherrer in the index); such mistakes are merely inartistic to foreign eyes, but when it comes to Year instead of Goodyear, and the page of the journal is also wrongly quoted, these mistakes become distinctly inconvenient. G. B.

Across the Gobi Desert. By Sven Hedin. Pp. xxii + 402 + 67 plates. (London: George Routledge and Sons, Ltd., 1931.) 25*s.* net.

THIS volume is the English edition of the account, originally published in Sweden, of Dr. Sven Hedin's great expedition to the Gobi Desert, or rather of the first stage, which in the winter of 1927–1928 brought him to Urumchi. The author considers this the greatest expedition of his life; and it was certainly a marvel of organisation and equipment. Unfortunately, it was impossible to carry out one part of the programme. At Urumchi the governor of the Province of Sikiang refused to allow the eight German airmen to fly over the inaccessible parts of the desert and they had to return home. In other branches of investigation, but especially in geology, geography, and archæology, the expedition has achieved some remarkable results, of which the scope is outlined in this book.

In the summer of 1928 Dr. Sven Hedin returned to Sweden to raise funds for the continuance of the work, and the expedition then became a joint Sino-Swedish undertaking with a staff of Chinese scientific workers and students collaborating with the European members. The author speaks in high terms of praise of his Chinese colleagues, both in regard to their scientific work for the expedition and in reference to his personal relations with them. Although it may be inferred that there have been difficulties in his dealings with the Chinese, Dr. Sven Hedin has no criticisms to offer; and indeed in so far as he might be cited as a witness on the question of friction between Europeans and the Chinese authorities, he would seem to suggest that in some cases at least the Europeans rather than the Chinese are to blame. He is, of course, referring only to matters in which the interests of science are affected.

The interval which has elapsed before the publication of the English edition of his book has enabled the author to add chapters dealing with the discoveries which have confirmed the fact of the diversion of Lop Nor Lake to its ancient bed after five hundred years, and to give its exact position as determined by members of the expedition in April 1931.

An Introduction to the Mathematics of Map Projections. By R. K. Melluish. Pp. viii + 145. (Cambridge: At the University Press, 1931.) 8*s.* 6*d.* net.

THIS book, in the earlier chapters, traces the history of projection, and presents an account of the general theory, together with deductions. Then follows a chapter on the theory of the indicatrix and the method of comparing one projection with another; next the question of finite measurements and the errors of finite representation. The last chapter is concerned with the selection, from mathematical considerations, of the best projection for a given country. The work is both useful and interesting, although not a complete treatment, even on the mathematical aspect of this subject. The title must not be taken to mean that the mathematics are therein explained. The reader will soon discover that it is assumed he has a fair knowledge of calculus to enable him to work out many details. The author has made no concessions to weaker mathematicians.

The book is "the outcome of a mathematical essay on maps written at Cambridge in 1922". The author was later influenced by Mr. A. R. Hinks, and by the late Mr. A. E. Young's work on the "Minimum Error".

In view of the interest which has recently been manifested in this subject of map projections, it is fortunate that a book dealing "comprehensively with the theories that underlie their construction" should have appeared. To the geographer with a mathematical bias this carefully prepared book will be especially welcome. J. E. C.

Properties and Mechanics of Materials. By Prof. P. G. Laurson and Prof. W. J. Cox. Pp. x + 353. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1931.) 17*s.* 6*d.* net.

Written for students of American universities and based on American standards and specifications, this book, within these limitations, constitutes a useful introduction to the subject, in that it combines an account of the stresses to which materials are subjected in constructional work with the description of the materials themselves. It is mainly of the nature of a preliminary survey, with the emphasis properly laid on fundamental principles, which it is desirable that the student should grasp thoroughly before allowing his attention to be diverted to specialised problems. The English engineering student will find in it a number of terms, units, and methods with which he may not be altogether familiar, but it will be useful to him in widening the range of his knowledge and giving him an insight into trans-Atlantic standards and practice. At the same time, the references to the conditions governing such characteristic American structures as the multi-story building, or 'sky-scraper', are by no means prominent, and one looks in vain for information on the subject of foundations. There is a list of references for further reading, but it is entirely American; no British or European standard books are quoted. B. C.

Hydraulics: a Textbook covering the Syllabuses of the B.Sc. (Eng.), A.M.Inst.C.E. and A.M.I.Mech.E. Examinations in this Subject. By E. H. Lewitt. (Pitman's Engineering Degree Series.) Fourth edition. Pp. xii + 372. (London: Sir Isaac Pitman and Sons, Ltd., 1932.) 10*s.* 6*d.* net.

This is a textbook which has been compiled for the specific purpose of covering the examination syllabuses of certain universities and professional bodies. It is, therefore, somewhat narrow and rigid in its treatment of the subject, but that it is popular with engineering students is evident from the fact that the work is now in its fourth edition. Indeed, as an examination textbook, it is admirably clear and concise. But as a general review of the subject it is, perhaps unavoidably, a little lacking in breadth. The chapter on flow through open channels, for example, gives the Chezy formula with Bazin's values for the coefficient, but takes no note of the elaborate, and more generally recognised, expressions of Ganguillet and Kutter, or those of Hazen and Williams, Manning, Barnes, and others. The present edition of the book has been enlarged to include new material on the viscous resistance of a fluid, and the sections on hydraulic machines have been considerably amplified. On page 174, the author is mistaken in attributing to the late Lord Kelvin the explanation of scouring at river bends: it is to his brother, the late Prof. James Thomson, that the credit is due. B. C.

(1) *Operational Methods in Mathematical Physics.* By Dr. Harold Jeffreys. (Cambridge Tracts in Mathematics and Mathematical Physics, No. 23.) Second edition. Pp. viii + 119. (Cambridge: At the University Press, 1931.) 6*s.* 6*d.* net.
(2) *Cartesian Tensors.* By Dr. Harold Jeffreys. Pp. vii + 93. (Cambridge: At the University Press, 1931.) 5*s.* net.

(1) A new edition of this really useful book is to be welcomed. The author has returned to Heaviside's notation of p for the operator, a distinct improvement. The chapter on Bessel functions has been rewritten and illustrated with reference to submarine cable telegraphy.

(2) While vector algebra demands the learning of a new notation, the tensor method is only a concise way of writing a notation which is already familiar. Special simplifications are introduced by the use of rectangular Cartesian co-ordinates, and tensor algebra is then a simple and useful tool for obtaining general theorems in a concise manner. In this excellent little book the notation is explained and illustrated by applications to geometry, dynamics, elasticity, and hydrodynamics.

The Archæology of Cornwall and Scilly. By Dr. H. O'Neill Hencken. (The County Archæologies.) Pp. xvii + 340 + 12 plates. (London: Methuen and Co., Ltd., 1932.) 10*s.* 6*d.* net.

Dr. Hencken's volume on Cornwall and Scilly, while following the plan of the series, is somewhat broader in its method of treatment. For this, the material is in part responsible. It was inevitable that such topics as the Cornish megalithic monuments and the burial chambers of Scilly, the position of Cornwall in prehistoric trade, its tin mining industry, and the relation of its legendary history to its archæology after the Roman evacuation should call for discussion on broad comparative lines. As a result, the book, while no less valuable to the archæologist than its predecessors, is even more attractive to the general reader.

Zoologie biologique. Par Prof. Étienne Rabaud. Fascicule 1: *Morphologie générale et système nerveux.* Pp. xxi + 223. (Paris: Gauthier-Villars et Cie, 1932.) 45 francs.

This is the first of three volumes which deal respectively with general morphology in relation to the nervous system, nutrition, and reproduction. The first volume approaches the problem of general morphology by describing the fundamental structure of all animal forms in terms of the integument, organs of locomotion, and the body cavities.

The relation of the organism to the environment is approached by the study of the peripheral nervous system, with special attention to the nerve endings of ordinary and special sensation. The author has succeeded in introducing many of the conceptions of modern physiology into morphology.

Theories of Hearing*

By Prof. H. HARTRIDGE, F.R.S.

RIVALRY still exists between the theories of hearing, because the small size, the delicacy, and the inaccessibility of the internal ear make direct observation and experimentation wellnigh impossible. Among the rival theories are the telephone theory, the modified telephone theory of Boring, the modified telephone theory of Watt, the volley theory of Wever and Bray, the pattern theory of Ewald, the stationary wave theory, and the resonance theory. At the present day, controversy principally centres round the resonance theory and some form of telephone theory.

THE TELEPHONE THEORY

According to the telephone theory, the ear behaves like a microphone. Variations of air pressure in the ears, at the frequencies of sound emitted by the source, are followed by the passage of impulses up the auditory nerve fibres to the brain. Like the electric currents in a telephone wire, these nerve impulses are controlled by the frequencies, intensities, and the phases of the incoming sound waves. The temporal lobe of the brain, on receiving these nerve impulses, interprets suitably the changes in pitch and quality which are heard, and assigns them to the musical instruments which are being employed.

The telephone theory encounters the following difficulty: experiment shows that the ear can hear frequencies up to about 15,000 vibrations per second. A telephone circuit transmitting these high frequencies would undergo 15,000 fluctuations in voltage per second. The ear, if it were behaving like a telephone, should therefore send up the fibres of the auditory nerve 15,000 impulses per second. But experiment shows that the highest frequency at which mammalian nerve fibres can transmit impulses is about 1000 per second. A modification of the telephone theory, called 'the volley' theory, meets this difficulty by assuming that a suitable co-ordinating mechanism exists in the internal ear. By means of this mechanism the auditory nerve fibres are divided into groups and each group in turn is called on to transmit an impulse. If there were 15 such groups, a frequency of 15,000 vibrations per second could be conveyed to the brain by nerve fibres which individually can only convey 1000 vibrations per second.

THE RESONANCE THEORY

According to the resonance theory, the ear contains a number of tuned structures, the natural periods of vibration of which correspond to the range of audible frequencies. Separate nerve fibres connect the sensory organs on these 'resonators' with different parts of the temporal lobe of the brain. In consequence, when sounds of one frequency are received, and one group of resonators vibrates, the sense organs of these resonators are stimulated and their nerve fibres convey impulses to one part of the temporal lobe. Sound waves of other frequencies will cause different groups of resonators to vibrate, and different parts of the temporal lobe will thus receive nerve impulses.

The resonance theory encounters the following difficulty: the vibrating structures in the ear have lengths of roughly half a millimetre, and the lowest audible frequency is approximately 20 vibrations per second. It is at first sight difficult to see how it is possible for such very short structures to perform vibrations in resonance to such low frequencies.

The formula for the fundamental frequency of vibration of a stretched string is as follows:

$$\text{frequency} = \frac{1}{2\ \text{length}} \times \sqrt{\frac{\text{tension}}{\text{mass per unit length}}}.$$

If, therefore, tension is suitably decreased at the same time as length, then frequency remains the same. It is therefore possible to have a fibre 0·5 mm. in length possessing a natural frequency of 20 vibrations per second, provided that the tension has a suitable value. The vibrating structures of the ear satisfy the required conditions.

EXPERIMENTAL EVIDENCE IN FAVOUR OF RESONANCE

Much experimental work has accumulated during the last few years which is in favour of the resonance hypothesis and against the telephone hypothesis.

(1) When by surgical interference a limited part of the internal ear is damaged, not only does deafness over a narrow range of frequencies result, but also the frequencies concerned correspond with the part of the internal ear which has been damaged. That is to say, if the damaged fibres are short, then high notes are involved; if, on the other hand, the damaged fibres are long, then low notes are involved.

(2) Boilermakers, in course of time, acquire deafness to high notes. Microscopic examination after death shows that the short fibres of the internal ear have been pathologically affected. Also, when animals are subjected for considerable periods of time to loud sustained musical tones, they become deaf to the musical tone to which they have been subjected. A microscopic examination of their internal ears after death shows that the fibres affected correspond approximately in length to the frequency of the tone to which the experimental deafness has been produced.

(3) When a musical tone, transmitted by a telephone circuit, is suddenly changed in phase by a half-cycle, the voltage fluctuations in the circuit continue almost without interruption.

When a musical tone, which is causing a tuned structure to perform resonant vibrations, is suddenly changed in phase by a half-cycle, the

* Friday evening discourse at the Royal Institution, delivered on April 29.

vibrations of the tuned structure are first arrested and are then re-established. On performing a similar experiment with the human ear, just after the change of phase the musical note is heard to undergo a short interruption, that is, the ear behaves as if it contained resonators, and unlike a telephone.

(4) When a musical tone is interrupted for short periods of time, similar interruptions can be identified in a telephone circuit which is excited by the sound. When a musical tone, which is causing a tuned structure to perform resonant vibrations, is interrupted for a short period of time, the vibrations of the tuned circuit are found to continue with only a small diminution in amplitude. On performing a similar experiment with the ear, it is found that short interruptions cannot be detected; hence the ear behaves as if it contained resonators, and unlike a telephone.

(5) When two musical tones differing considerably in frequency, for example, 200 v. per sec. and 250 v. per sec., are sounded simultaneously into a telephone, the voltage fluctuations in its circuit are found to correspond to a single frequency of 225 v. per sec. with periodic increases and decreases of amplitude (beats) occurring 50 times a second. When the above two tones are caused to set up vibrations in a graduated series of resonators, two separate groups of resonators are found to be set into vibration, one corresponding to 200 v. per sec., the other corresponding to 250 v. per sec. A careful examination of the groups shows that neither of them is exhibiting appreciable beats. On performing the experiments with the ear, the two separate tones of 200 v. per sec. and 250 v. per sec. are heard and no beats are to be observed; hence the ear behaves as if it contained resonators, and unlike a telephone.

(6) When two musical tones having frequencies in the ratio of 1 to 3 are sounded simultaneously, the voltage fluctuations in a telephone circuit excited by them are found to be greatly affected by the relative phases between the two tones. In one phase relationship a single sharp peak curve is produced. In another phase relationship a double hump curve is produced. When the above two tones are caused to set up vibrations in a graduated series of resonators, two groups of resonators are found to be set into vibration, one group for each tone. The careful examination of the groups shows that neither their frequency nor amplitude is affected appreciably by changing the relative phases of the two tones. On performing the experiment with the ear, it is found that changing the relative phases of the tones has no effect on the sounds which are produced; that is, the ear behaves in accordance with the resonance theory and contrary to the telephone theory.

(7) It is well known that resonators exhibit the properties of selectivity (sharpness of resonance) and persistence, and that both these properties are related to the frictional losses to which the resonators are subject. In consequence of this, when different degrees of selectivity are multiplied by corresponding degrees of persistence a constant value is obtained, as is shown in the following table:

S (selectivity).	P (persistence).	$S \times P$.
1·5	40	60
2·0	30	60
3·0	20	60
4·0	15	60
6·0	10	60

(Selectivity in the above table is the percentage difference of frequency causing one-tenth the amplitude of that caused by the intune frequency at the same energy level. Persistence is the number of vibrations which correspond to the time required for the amplitude to be reduced to one-tenth its initial value.)

Now, the selectivity of a graduated series of resonators can be ascertained experimentally by finding the smallest difference of frequency which causes beats owing to the overlap of the two vibrating groups of resonators. The persistence of a series of resonators can be ascertained experimentally by finding the duration of the longest interruption in the incoming sound energy which produces no observable decrease in amplitude. Both these methods of research are applicable to the ear, and the table below gives the values I obtained. The last column shows that their product gives a reasonably constant value, as should be the case if the ear resonators are of the kind familiar to the physicist.

Tone.	S.	P.	$S \times P$.

REPLIES TO OBJECTIONS TO THE RESONANCE THEORY

(1) In a piano the wires are all separated from one another and are therefore free to vibrate individually. It is not difficult therefore to picture a small group of wires, or even a single wire, being set into resonant vibration. In the internal ear, on the other hand, the resonating fibres are seen under the microscope to be attached sideways to one another. How is it that these attachments do not impede or even stop resonant vibrations, or at the very least produce an irregular jangling?

In replying to this question, two points require emphasis; first, that when a group of resonators is being set into vibration by incoming sounds, those above and those below the frequency of the resonator which is strictly in tune with that of the sound are performing what are aptly called 'forced vibrations'. They do not perform vibrations at their own natural frequency, but vibrate at the frequency of the incoming sound energy. Thus, suppose a group of wires of a piano to be set into resonant vibration by a strong source having a frequency of 200 vibrations per second. Then, a stroboscopic examination of the vibrating wires should show that those on one side of the intune resonator are all moving towards or away from the observer at the same time.

Secondly, the number of fibres of the internal ear set into forced vibration by a pure source of sound is much more numerous than is usually supposed. If, having ascertained the fibre strictly 'in tune' with the musical tone, we count sixty fibres above it in pitch, on examining this fibre we should find *that it is performing vibrations* with an amplitude which is approximately one-tenth the amplitude of the 'intune' fibre. The sixtieth fibre below the intune one is also performing vibrations with an amplitude of one-tenth the intune one. Since so many fibres are affected, the difference in amplitude between one fibre and its next-door neighbours is very small; calculations show that they nowhere exceed 5 or 6 per cent. The attachments of the fibres to one another should therefore not markedly impede their vibration, and are therefore not incompatible with the resonance theory.

(2) So long as the incoming vibrational energy continues, resonators continue to vibrate; when this energy ceases, they gradually come to rest in an exponential manner. If the ear contained resonators, on the cessation of a musical tone we ought to be able to hear a gradual diminution of loudness. Everyday experience shows us, however, that silence appears to follow the cessation of musical tones almost immediately, and this is incompatible with the resonance theory. The explanation of this objection is as follows: If we know the threshold of stimulation of the sense organs attached to the fibres in the internal ear, and if we know the degree of persistence of the ear, we can readily calculate the time taken for the vibrations of the fibres to be reduced until 'silence' is reached. The values thus obtained for notes of medium loudness are given in the following table:

Tone.	Time in Seconds for Termination of Hearing.
128	0·057
256	0·036
512	0·021
1024	0·012

We see that these times are very short. Even for a tone of 128 vibrations a second, the time of the termination of hearing is less than one-seventeenth of a second. Our experiences, therefore, are not incompatible with the resonance theory.

(3) Pathological changes in the internal ear are sometimes found to produce deafness to one or more groups of frequencies. Whereas most tones, both high and low, are heard in a normal manner, there is deafness to certain intermediate ranges of frequency. It is often found that a frequency inside this range can be correctly perceived if its intensity be much increased. This finding is held to be incompatible to the resonance theory, on the following grounds: Suppose a certain number of fibres of the internal ear to be destroyed, then it is clear that the ear will be deaf to tones corresponding in frequency to the damaged fibres. If now a tone of sufficient intensity be sounded, which corresponds in frequency to the centre of the damaged region, normal fibres at the edges of the deaf region should be caused to perform vibrations. Provided that the stimulating tone be loud enough, the forced vibrations should have sufficient amplitude to stimulate their respective sensory end organs. The individual should now hear one or more musical tones which correspond to the frequencies of these normal fibres. But experiment shows that what he does hear is a tone which corresponds to the frequency of the tone which is being sounded.

An example may make matters clearer. Suppose a man to be deaf to frequencies of from 200 to 240 vibrations per second, owing to complete destruction of the fibres which correspond to this region. Then on sounding a tone of 220 vibrations a second of ordinary intensity, nothing is heard by the affected ear. On sufficiently increasing the intensity of the sound, however, there should be, according to the resonance theory, forced vibrations on the part of the normal fibres just below 200 vibrations per second and just above 240 vibrations per second, and therefore the individual should hear two musical tones corresponding to these frequencies. Experiment shows, however, that what he does hear is a single musical tone corresponding to 200 vibrations per second, a result which, it is claimed, is incompatible with the resonance theory.

The reply to this objection is that its supposed pathological basis is unsound. Regions of deafness are not due to clean-cut destruction of certain fibres leaving neighbouring fibres intact, but rather to localised adhesions and exudates interfering with the normal vibrations of the fibres. In consequence, a tone of normal intensity sets the affected fibres into such feeble vibration that their sense organs receive insufficient stimulation. A more intense tone, on the other hand, may cause sufficient amplitude of vibration for the stimulating tone to be recognised. The behaviour of an individual with islands of deafness is not, therefore, incompatible with the resonance theory.

(4) It is found by experiment that a dog in which a limited number of fibres of the internal ear has been destroyed by a drill, exhibits afterwards deafness to a very small range of frequencies. Now, according to the resonance theory, many fibres are affected by a single frequency, and therefore deafness to a considerable range of frequencies should occur. Since this is not found to be the case, this experimental result is claimed to be incompatible with the resonance theory.

The reply to this objection is as follows: Suppose the part of the internal ear affected by the drill to be one millimetre in width. Then it is found by calculation that approximately 350 fibres would be destroyed. Now, we have evidence that one musical tone affects approximately 200 fibres, so that it is clear that the deaf region would correspond to the difference between these two values, namely, 150 fibres only. These would correspond to a piece of the cochlear 0·4 mm. in length, a length which is less than half that affected by the drill. The experimental finding that the deaf region is narrower than the destroyed region is in agreement with the resonance theory.

(5) In recent experimental investigations on the auditory nerves, Wever and Bray have detected

electric currents which correspond in frequency and phase to the sound waves falling on the ear. This would be the case if the auditory nerve were behaving like a telephone circuit, and if the internal ear was acting like a microphone. This evidence, which is in favour of the telephone theory, is at variance with the resonance theory. Now, Adrian, who has recently repeated Wever and Bray's experiment, found that freezing or crushing the auditory nerve, or putting novocaine on it, did not stop the effect, which cannot, therefore, be due to the passage of nerve impulses along it.

It would seem that the phenomenon, interesting as it is, has nothing directly to do with the behaviour of the internal ear, so far as normal hearing is concerned. There would appear to be no justification at the present time in claiming these experiments as being in agreement with, or in contradiction to, the various theories of hearing.

(6) According to the resonance theory, a great many fibres are set into vibration by a single pure tone, and fibres at the edges of the group differ from the centre one, which is 'in tune' with the incoming vibrations, by roughly a semitone. Why, then, do we not hear a dissonant noise when a single frequency falls on our ears? Gray has answered this objection by supposing that in some way the sense organs attached to the fibres are able to detect the fibre which is performing the maximum amplitude of vibration; and that the brain, receiving impulses of a special kind up the nerves connected with this fibre, is able selectively to receive the frequency corresponding to this fibre and to ignore the impulses from all the other more outlying fibres which are set into vibration by the tone.

Not only is it extremely difficult to see how a suitable physiological mechanism could be devised to do this, but also it would place the ear in a completely different category from that of vision and touch. In vision, we meet a corresponding phenomenon, for a point source of light stimulates not one cone sense organ of the retina but many cones. This effect causes no confusion. We always have seen point sources (for example, stars) that way. We presumably shall continue to do so all our lives. So with hearing. Single pure tones have always set a certain number of fibres into vibration; it is an effect to which we are accustomed. It would seem entirely unnecessary to invoke a special, and unusual, type of mechanism to deal with the phenomenon.

CONCLUSION

When, fourteen years ago, Wrightson published his book, the telephone theory received at his hands an impetus which was just what it required. The resonance theory had fallen into disrepute, the telephone was replacing it, and people were hesitating between the two. Unfortunately for the telephone theory, it was not long before criticisms of Wrightson's book began to accumulate. So serious were these criticisms that Wrightson's views had to be wholly abandoned. Since then, evidence has been accumulating in favour of the resonance theory. Objections to it appear in many cases to be based on erroneous ideas with regard to resonators and sense organs. It would seem, at the present time, that the resonance theory accounts satisfactorily for all the phenomena of hearing, and that no other theory does this.

Royal Society of Canada

ANNUAL MEETING IN OTTAWA

ON May 26–28 the Royal Society of Canada met in the new building of the Canadian National Research Council in Ottawa. Several features of the meeting arose out of the fact that the Society was celebrating its jubilee. Learned societies of Great Britain, France, and the United States sent delegates. The presidential address by Sir Robert Falconer, on the evening of May 26, was an eloquent and instructive survey of the remarkable progress of the intellectual life of Canada during the past half-century, as reflected in the proceedings of its Royal Society and, in fact, dominated by the fellows of the Society. This address and a series of detailed histories of the progress in special fields are assembled in an anniversary volume, entitled "Fifty Years' Retrospect". At the same evening meeting, delegates were received, a diploma was presented to the Prime Minister, Mr. Bennett, and the various medals were awarded, namely: the Flavelle Medal to Dr. J. S. Plaskett for his contributions to astronomy, the Lorne Pierce Medal to Dr. Archibald MacMechan for achievements in literature, and the Tyrrel Medal to Dr. Pierre-Georges Roy for his historical researches.

A new function of the Society appeared in the announcement by the Council of the award of ten fellowships endowed by the Carnegie Institution.

At the meetings of Section 1 (French Literature and History) twenty papers were read, and of Section 2 (English Literature and History) twenty-five papers were read.

The presidential address to Section 3 (Physics, Mathematics, Astronomy, and Chemistry) was delivered by Prof. A. Norman Shaw, who gave an interesting account of the developments in physics during the last fifty years. He paid tribute to the work done by physicists in Canada, dwelling especially on the contributions made at McGill by the late Prof. H. L. Callendar, Lord Rutherford, and by Prof. J. C. McLennan in Toronto. After reviewing the work in physics of the past and present fellows of the Section, he concluded his interesting address with a plea for closer co-operation between science and government with the words: "We await Governments which will devote their major expenditures of effort, time, and money in studying and directing the efficient harvesting and even

distribution of the knowledge and power which Science places at their disposal ".

More than a hundred papers were presented to Section 3, which split up into the three divisions of physics, chemistry, and mathematics (including astronomy) in order to get through the programme during the meeting. In the physics division, interesting papers were given by Prof. L. V. King on " New Singular Solutions of Maxwell's Equations and Applications to the Calculation of Radiation Fields of Wireless Antennæ ", in which he demonstrated that the exact theory of radiating antennæ could be given. Prof. J. A. Gray gave several papers on the scattering of β-rays. His results indicated that the range of β-rays from radium-E are much greater than the values found by other observers, the range in aluminium and lead being about the same. The loss of energy in the scattering increased with increase in angle of scattering, but could not be accounted for by penetration of the nucleus. The loss in energy, amounting to 20 per cent, went off in the form of radiation which was not X-rays. Dr. R. W. Boyle presented a number of papers by the members of the Canadian National Physical Laboratory on various topics. In a paper on the passage of ultra-sonic waves through thin plates of glass, the experimental results showed that Rayleigh's theory is inadequate. C. D. Niven spoke on heat insulation of fibre boards, G. C. Laurence on a new type of γ-ray ionisation chamber for radium calibration, and L. E. Howlett on " Some Theoretical Considerations on the Intensities of Raman Lines ". Prof. A. N. Shaw described a new theorem by which all the thermodynamical relations involving first and second derivatives of the different variables for a simple substance can be rapidly deduced.

There were several papers on applied geophysics, amongst which Prof. L. Gilchrist's application of geophysical methods to the determination of stake resistances of earth contacts associated with power transmission lines and Prof. L. V. King's mathematical investigation on potential problems in semi-infinite stratified media were of interest. Dr. G. M. Henderson and S. Bateson spoke on a quantitative study of pleochroic haloes. Prof. A. S. Eve gave an interesting account of proposed experiments on the Kennelly-Heaviside layer during the total solar eclipse of Aug. 31 this year, when observations will be made to detect a possible eclipse of particles emitted by the sun. Dr. H. T. Henderson added some remarks on the work being undertaken in England on the determination of the height of the K-H layer. The secretary of the Section, Mr. J. Patterson, presented a paper on " A Source of Error in Measuring Radiation on a Horizontal Surface ", and Mr. Andrew Thomson a paper on the results of an analysis of 171 pilot balloon observations taken in the central Pacific from the research yacht *Carnegie*, from which the trade and anti-trade wind circulation in the Pacific was deduced. Prof. H. A. McTaggart gave an account of a study of Brownian movement in thin films of various substances on water or aqueous solutions.

Among the numerous papers on spectroscopy, Prof. J. K. Robertson gave an account of the change in the type of spectra, from the spark to the arc spectrum, with the presence of continuous bands when thallium vapour at different temperatures is excited with the electrodeless discharge. Damped and continuous waves were used and different effects obtained. Prof. J. C. McLennan and his co-workers presented several papers. A definite change in the scattering of light was observed at the critical point in liquid helium. In association with H. D. Smith, the Raman effect in liquid and solid carbon dioxide was found to give four frequency changes which were the same as those found in the gaseous state. The absorption spectrum in the band spectrum of xenon was investigated, and in another paper the wavelengths of some copper lines in the extreme ultraviolet were accurately measured with a Fabry-Perot interferometer and a spectrograph. Prof. J. S. Foster described the mounting for a thirty-foot grating spectrograph for observing the flash spectrum during the coming solar eclipse. A paper on the Stark effect in the red region of the xenon spectrum, by J. F. Heard, indicated a Stark displacement in 89 lines.

Among the dozen papers in the mathematics and astronomy division, Prof. S. Beatty spoke on geometric characterisation of lineal transformations; S. A. Lischinsky and W. J. Webber on the representation of almost all positive integers in the form plus square; and Dr. J. Synge on variational principles and dissipative systems. Dr. W. E. Harper gave a paper on the wave-lengths of *A*-type stars and also one on the orbits of four spectroscopic binaries.

More than forty papers were presented in the chemistry division. Of the several papers presented by Prof. O. Maass and his students, two dealt with the absolute density of dry cellulose and the sorption of sodium hydroxide on cellulose and on wood. Another paper, by A. R. Williams, Prof. O. Maass, and Prof. F. M. G. Johnson, described the results of the measurement of the heats of solution of sulphur in carbon disulphide over a large range of concentration, from which an estimate of the total surface energy of sulphur was made. Energy transfer between complex gas molecules and solid surfaces was dealt with by E. W. R. Steacie and H. A. Reeve. Dr. R. H. Clark presented several papers on the separation of rare earth elements. Prof. H. E. Bigelow read a paper on the production of *p*-nitrobenzaldehyde by sodium arsenite, in which the results were materially different from those obtained when other reducing agents were used.

Prof. C. A. Chant was elected president of the Section for the 1933 meeting, and Mr. John Patterson continues as secretary.

Section 4 (Geology) received twenty-four papers, several of which were read by title. The papers actually presented evoked interesting discussion at the well-attended meetings. An important report by the National Committee on Stratigraphical Nomenclature was presented by F. I. Alcock. A

series of papers on batholiths was a prominent feature of the meeting, the contributors being S. J. Schofield, F. A. Kerr, H. C. Gunning, Prof. J. S. De Lury, and J. F. Wright. A new theory of the source of the siliceous solutions from which asbestos is produced was put forward by H. C. Cooke in a paper on their silica content. G. A. Young reviewed fifty years of geological investigation of the Canadian Shield, stressing the changes which have taken place and may yet take place in the fundamental ideas regarding this branch of geology.* The president-elect of the section is Prof. E. L. Bruce.

In Section 5 (Biological Sciences) ninety-six papers were read, part of the time in divided session. In his presidential address, Prof. J. B. Collip reviewed the work carried out under his direction on the œstrogenic substances and the anterior pituitary-like substance of the human placenta. Various aspects of this work were later discussed in detail by some of his collaborators. The interrelation of calcium metabolism with the parathyroid glands and with irradiated ergosterol was the subject of a series of papers by other members of the same department and also by Prof. N. B. Taylor. Prof. C. H. Best discussed the possibility of preventing fatty degeneration of the liver in diabetic animals by administration of choline, and presented a series of papers by Dr. D. A. Scott on the chemistry of insulin. Prof. J. G. FitzGerald read papers from his laboratory in the field of immunology. Important papers were also read by Prof. S. E. Whitnall on the causes of exophthalmos, and by Prof. B. P. Babkin on the liberation of a hormone from the nerve-endings of the chorda tympani.

The life of reindeer and other mammals in relation to segregation, sexual isolation, and evolution of species was discussed by Prof. Seymour Hadwen. Prof. A. Willey described a new species, *Nebaliella Caboti*, the first of the genus recorded from the North Atlantic, and showed that another form, *Epineballia pugettensis*, is distinguished generically from *Nebalia* by the structure of the male. Prof. E. M. Walker presented several papers, amongst which may be mentioned one by F. P. Ide on the effect of the temperature gradient of a stream upon the insect fauna, and another by himself on prognathism and hypognathism in insects. One food chain of the sea, from diatoms to fish through copepods, was demonstrated in a paper by C. W. Lowe, presented by Prof. A. H. R. Buller.

The botanical papers were varied and interesting. Those dealing with morphology, including a correlation of resin cyst production in hemlock, in response to wounding with seasonal growth; an account of the origin of rays in Gymnosperms in relation to taxonomy (both papers by M. W. Bannans); and an account of the organisation of the young sporophyte of *Isoetes*, based on anatomy, in comparison with that of other Pteridophytes (by W. K. W. Baldwin) were presented by Prof. R. B. Thomson. Prof. Marie Victorin recorded several examples of the transformation of the concrescent carpels of *Aralia nudicaulis* into five simple leaves or leaflets. Dealing with fungology were several papers from Prof. Thomson's laboratory on the subject of rusts and other fungi, and a very interesting account of hyphal fusions and their significance by Prof. A. H. R. Buller. Plant physiology included some important papers by Prof. G. H. Duff and Dorothy Forward, on respiratory metabolism and sugar changes in wheat leaves kept in the dark, and on the influence of this on their reaction to rust infection. Prof. F. E. Lloyd criticised M. Kruck's revival of the theory that the door of the trap of *Utricularia* is an irritable mechanism. An intensive study of the water balance of certain Canadian trees throughout the year and its bearing on problems of tree physiology was given in a paper by R. D. Gibbs. Dealing with cytology and genetics were papers by Prof. C. L. Huskins, adducing evidence of the homology between somatic mitosis and germinal meiosis, which indicated that the latter is brought about through retardation of the splitting of the chromonemata during the last premeiotic division. Taxonomy and ecology were represented in a series of papers by Prof. Marie Victorin and his associates. Of especial interest was the account of ecological modifications in the riparian flora of the St. Lawrence River, due to exceptional low water levels, and of the spread and adaptability (for example, to growth in deep water) of the introduced species *Butomus umbellatus*. Prof. J. G. FitzGerald was elected president of the Section.

The president of the Society for the ensuing year is Prof. Francis E. Lloyd, Macdonald professor of botany in McGill University.

Obituary

Prof. G. Baldwin Brown

We regret to record the death of Emeritus Prof. Gerard Baldwin Brown, which took place at Edinburgh on July 12, at the age of eighty-two years. Born in London on Oct. 31, 1849, he was educated at Uppingham and Oriel College, Oxford—of which later he became a fellow—obtaining a second class in Honour Moderations and a first class in Literæ Humaniores in 1873. His success in winning the Chancellor's prize for an essay on "The Short Period during which Art has remained at its Zenith in Different Countries" was an early indication of the bent of his mind, a bent which was further strengthened by his election as a fellow of Brasenose College, where he was brought into touch with Pater. He left Oxford to take up painting in London, and was afterwards appointed the first Watson-Gordon professor of fine art in the University of Edinburgh, at the early age of thirty-one. This chair he held for fifty years, retiring at the end of the academic year 1930, a period equalled only twice in the annals of the University.

Baldwin Brown's early essay in the history of art while he was still at Oxford had indicated that his

approach to art was archæological and historical rather than purely æsthetic; and interest in that line of inquiry grew as his life-work developed. His earliest book was "From Schola to Cathedral", a study of early Christian architecture. His outstanding and most enduring work is "The Arts in Early England", a monumental effort and an established authority, in five completed volumes and part of a sixth, published at intervals between 1903 and 1930, which displays a wide knowledge of the facts and indefatigable industry. In it, as in a smaller but comparable work, "The Arts and Crafts of our Teutonic Forefathers", he stressed—unduly, many archæologists would now say—the contribution of the Teutonic races in the artistic origins of Britain and North and Central Europe generally. The knowledge of æsthetic principles and theory which Baldwin Brown brought to bear on the archæological problem in his larger work was also used to advantage when dealing with palæolithic art in "The Art of the Cave Dweller" (1928), his Munro Lecture, a book for the preparation of which he had visited the caves of France and Spain, though then nearly eighty years of age, and in which the large number of illustrations, many of them of the less known examples of cave art, was used with striking effect in demonstrating with precision, from what to most archæologists was a new point of view, the æsthetic qualities of palæolithic painting and engraving, as well as the intentions and achievement of the artist.

In addition to the books already mentioned, Baldwin Brown was the author of "Anglo-Saxon Architecture", "The Life of Anglo-Saxon England in relation to the Arts", "The Care of Ancient Monuments", and a number of books on individual painters or matters of artistic technique. He was a fellow of the British Academy, of the Finnish Archæological Society, of the Yorkshire Philosophical Society, an associate of the Royal Institute of British Architects, and hon. LL.D. and D.Litt. of the University of Edinburgh.

We regret to announce the following deaths:

Prof. Fran Jesenko, professor of botany in the University of Ljubljana, Yugoslavia, known for his work on the genetics of wheat and rye, on July 14, aged fifty-seven years.

Prof. Graham Lusk, For.Mem.R.S., professor of physiology in Cornell Medical College, New York, a distinguished worker on the physiology of nutrition, on July 18, aged sixty-six years.

News and Views

A Century of Medicine

The Right Hon. Lord Dawson of Penn delivered his presidential address at the centenary meeting of the British Medical Association on July 26, taking as his subject "A Hundred Years and After". Lord Dawson traced the art of healing from the Egyptian Imhōtep (*circa* 3000 B.C.), through the well-known Greek era, to the Christian era, where at the beginning there was a retrogression, Christianity at that time delaying rather than promoting medical progress. The greater part of Lord Dawson's address, however, was devoted to the directions along which medical knowledge has grown during the last hundred years. The Reform Bill of 1832 forced masses of the population to dwell in towns, with the result that the prevailing conditions, due to lack of knowledge of public health and sanitation, caused misery, ill-health, and discontent. During the year of the Association's birth, there was a cholera epidemic raging over England and Wales, during which the number of deaths exceeded 50,000. At that time the idea prevailed that epidemic diseases were visitations beyond our ken and control. Even then, however, great minds were working: Virchow in cellular pathology, Bernard in physiology, Bright in medicine, and Chadwick in sanitation.

Medicine and the Basic Sciences

The dawn of the new era in medicine occurred, however, in 1857, with Pasteur's discoveries. These were soon followed by those of Lister, and thus began a quick succession of discoveries by men well known in the history of science and medicine. To-day there is a stronger link with medicine and the pure sciences. Physics and chemistry, with physiology, have taken pride of place in their services to medical knowledge. Radiology has the discoveries of Röntgen and others as its basis. Chemistry has afforded incalculable aid to therapeutics. The value of the scientific investigations of the seven known vitamins to medicine need scarcely be emphasised. Hormones and virus diseases are now of great importance to the study of physiology and pathology. The kinship between medicine and education was also emphasised by Lord Dawson. Still closer co-operation is required in the quest for knowledge. The Medical Research Council is doing a great service in supporting and directing efforts, wherever they come from, and it maintains contact between workers and between the institutions to which they belong. "There is, however, need for further co-ordination among bodies which represent varied aspects of medical knowledge such as the basic sciences, medicine, surgery, obstetrics, education, and administration."

Progress of Rational Medicine

Sir Charles Hastings, founder of the British Medical Association, was a native of Worcester, and part of the centenary meetings of the Association took the form of a visit to Worcester on July 24 and a commemorative service in the Cathedral, with a sermon by Dr. E. W. Barnes, Bishop of Birmingham. Dr. Barnes's text was "Honour a physician with the honour due unto him" (*Ecclesiasticus*, xxxviii. 1). Modern science and medicine began with the publication by Copernicus of his heliocentric astronomy and the production by Vesalius of his work on the anatomy of the human body. Nearly four centuries have

passed since then, and the human mind, freed from the shackles of medieval authority, has advanced at an ever-increasing rate. Great progress has been made in medicine and science, and the "new biology exhilarates by its possibilities"; advance along present lines gives visions of a great measure of immunity from disease and a finer race of men than the earth has yet known. Progress depends, however, in medicine as in science, on the unprejudiced search for truth, on original investigation. During the nineteenth century, conditions became increasingly favourable for medical research, until now it is well organised and receives State support. But what of the future? Dr. Barnes fears that we are not yet safe from religious reaction. New aspects of truth often bewilder and arouse instinctive opposition, which in turn invokes religious sanctions. Pseudo-religious prejudice opposes eugenic measures, as dissection and vaccination were opposed in the past, and faith cures may be associated with impatience of the sufferer with half-won knowledge. Social leaders, religious teachers, scientific workers, and medical men must join in emphasising that man has been endowed with his rational powers in order that he may discover the truth. Science is dynamic, and our faith, likewise, is the more inspiring because it also is dynamic.

British Medical Journal

THE issue of the *British Medical Journal* for July 23 is a special number commemorative of the centenary of the British Medical Association, which has been celebrated during the past week in London. Sir Humphry Rolleston contributes a review on "Changes in the Medical Profession and Advances in Medicine during Fifty Years", and Sir D'Arcy Power, in "A Century of British Surgery", describes the progress of surgery. The history of the Association is surveyed in a special article entitled "The First Hundred Years", with portraits of Ernest Hart and Sir Dawson Williams, prominent among the editors of the *British Medical Journal*. A notice is also devoted to Sir Charles Hastings, the founder of the Association, and the Association's headquarters in Tavistock Square, London, are described, with a coloured plate illustrating the imposing Great Hall.

Park Wood, Ruislip

ON July 23, the Earl of Crawford and Balcarres, who is chairman of the Council for the Preservation of Rural England, declared Park Wood, Ruislip, in Middlesex, a sylvan area of 237 acres, and the property of King's College, Cambridge, as dedicated for public use, in perpetuity. It has been acquired through the assistance of the Middlesex County Council, coupled with that of the Ruislip-Northwood Urban District Council. Complementary to the above is the gift by the College of the ancient manor house, its farm buildings, old-world gardens, and lofty and impressively timbered barn, one of the largest in the country, which accommodated nearly three hundred persons at the ceremony. Lord Crawford expressed the hope that the woodlands might always remain as such, and be truly English in character. The kindly agencies of Nature would sanctify them through their flora and fauna, and in particular there was the inspiration of bird life. Congratulations were extended to the provost and fellows of King's College on the happy arrangement effected.

THE Bursar of King's College, during his speech, recalled the original connexion of the College—extending over five centuries—with this Middlesex parish. It dated, in fact, from 1461, when Henry VI. granted to the provost, Robert Wodelark, and the scholars of the College, "the Manor of Ruyslepe . . . and all lands belonging". The king had, in 1440–41, entrusted to three commissioners his authority to proceed in the matter of a college which he proposed to found, and had indeed lived to see the magnificent chapel of King's completed. It was a sister foundation to that at Eton. In the nineteenth and twentieth centuries many changes have been experienced by the College, as trustees, whilst 'town-planning' schemes and urbanisation have cast their burden of responsibility. The Bursar disclosed that, so late as 1906, an offer of no less than £48,000 was made by a syndicate for the establishment of a racecourse; the offer was withstood, however, by the casting vote of the provost of that time.

Early Man in America

A FURTHER detailed research report on the discoveries of flint implements said to be associated with fossil remains of Pleistocene mammals in Nebraska, to which we referred in our issue for July 16, p. 87, has been made to Science Service, Washington, D.C., by Dr. W. D. Strong, of the Bureau of American Ethnology. It presents several points of interest. The Cumro find of an arrow-head, or rather 'point', associated with the extinct *Bison occidentalis*, lay under 16 ft. of loess of 'Peorian age', which is thought by the discoverer to be prior to the last or Wisconsin glaciation; but Dr. A. L. Lugn, of the University of Nebraska, the specialist in Nebraskan and Iowan Pleistocene deposits, regards this dating with some doubt, as some 'Peorian' deposits are unquestionably recent. On the other hand, the same authority, after a personal examination of the site of discovery of the second flint implement on the Platte River, also said to have been associated with *B. occidentalis*, while recognising that the exact age cannot be determined with finality, is of the opinion that the deposit shows considerable antiquity. It may be of 'Peorian' age; and it shows Kansan sands and gravels as the basal member. It has also transpired that the association of flint artefact and remains of *B. occidentalis* is supported by a hitherto unreported discovery in 1923, when a chipped point was found in association with a skull and part of the skeleton of this extinct bison in the Meserve quarry. By far the most interesting find, however, from the point of view of dating, is that at Angus, where the "Folsom type arrow-point" was associated with the mammoth. Unfortunately, here the association lacks corroboration; but the sands and clays in which the mammoth bones were laid down appear to belong to the Yarmouth interglacial, which corresponds with the Mindel-Riss of Europe. In any event, the implements belong to a hunting culture hitherto unknown in Nebraska.

Military Conquest and Civil Settlement

FOR his presidential address to the Devonshire Association on June 21 Mr. J. J. Alexander surveyed "The Saxon Conquest and Settlement". Although he gave a very wide interpretation of his subject, devoting a considerable portion of his address to the question of evidence—historical, legal, and scientific—yet he brought together a useful résumé of what has been written on the matter. He made great use of the recently published volume of the Place Names Society on Devonshire, and summed up his paper by arriving at six probable conclusions: the first, as to the sparsity of the population of the district in the seventh century, and the remaining five regarding the campaigns of the seventh and eighth centuries in the west of England. Mr. Alexander has not, however, distinguished quite sufficiently between conquest and settlement. The military leaders and their soldiers prepared the way for the settlers who later, and sometimes much later, came with their wives, families, and baggage and travelled perhaps by a different route from that by which the soldiers marched. The study of place-names is most important for the history of the Saxon period, but, besides archæology and written history, it needs to be supplemented by studies of the varied systems of agriculture and the distribution of types of villages by the aid of the ordnance map—"that marvellous palimpsest which, under Dr. Meitzen's guidance, we are beginning to decipher", as Prof. Maitland has pointed out. Something has been done in this respect for eastern England, where the evidence is clearer, but in the west, where the evidence is more confused and difficult of interpretation, the subject has received little attention.

Prehistoric Society of East Anglia in 1931

THE recently issued *Proceedings of the Prehistoric Society of East Anglia* for 1931 (vol. 6, pt. 1) contains a number of communications of importance for prehistorians. The presidential address by Mr. J. P. T. Burchell on "Early Neanthropic Man and his Relation to the Ice Age" has already been the subject of reference in NATURE (Nov. 21, p. 879; 1931). It is printed here in full with ample illustration. Among the remaining papers, Mr. Bertram Brotherton describes a remarkable rostrocarinate implement of quartzite from Worcester, upon which Mr. Reid Moir remarks that it may be less ancient than its type suggests. Mr. Reid Moir himself chronicles further discoveries of flint implements in the brown boulder-clay of north-west Suffolk. He is now inclined to think that the brown boulder-clay was laid down before the Magdalenian period began. In a paper on the flint industries of the type station of La Madeleine, Mr. A. S. Barnes discusses their value as a basis for the classification of Magdalenian industries elsewhere. Mr. A. Leslie Armstrong deals with his further excavations in the Pinhole Cave at Creswell Crags and on a late Aurignacian site in Lincolnshire. Mr. A. L. Grimes, in dealing elaborately with the early bronze age flint-dagger in Britain, suggests that while it was undoubtedly introduced into Britain with the beaker culture, it shows resemblances to both the two main Continental groups, the northern and the Mediterranean. An account of the excavation of an early iron age site at Great Wymondham, Herts, by Mr. C. F. Tebbutt, is especially noteworthy, as sites and finds of this 'early phase' (La Tène I. and II.) are rare in that area.

John Fitch, Pioneer of Steam Navigation

IN the June issue of *Mechanical Engineering*, Mr. W. H. Richardson gives a sketch of the career of "John Fitch: Patriot, Martyr, Pioneer Steamboat Inventor". Fitch was born in 1743 and died by his own hand in 1798, having during the last fifteen years of his life devoted himself with fluctuating fortune to the promotion of steamboat enterprises. He was the first in the world to form a steamboat company and to place a steamboat in service for carrying passengers. His work was done at a time when there were no engineering shops in America and when the export of machinery from England to the United States was prohibited, and there can be little question that had he had the assistance of Watt and Murdock and their fellows, his schemes could have been brought to a successful issue. Above all, however, he was a man of vision, and while realising the great value of steamboats on the great waterways of America, he once wrote of steam navigation, that "The Grand and Principle Object must be on the Atlantick, which would soon overspread the wild forests of America with people and make us the most oppulent Empire on Earth". The earliest experiments of Fitch were made on the Delaware between 1786 and 1790, and were contemporary with those of Rumsey on the Potomac and of Miller and Symington in Scotland. To-day there is a monument at Trenton, on the "John Fitch Way" beside the Delaware, marking the site of the New Jersey terminus "of the first merchant marine highway in the world".

Heating the Soil Electrically

THE South Wales Electric Power Company of Cardiff is distributing pamphlets to farmers giving them useful information on the advantage of the electrical heating of the soil in frames used for growing vegetables and fruit for the early market. The soil is heated by means of a 'thermal' cable buried in the soil and carrying at certain times of the day electric current. British and continental firms are now manufacturing this kind of cable, and an electrical contractor will install it. This pamphlet demonstrates by photographs how much more rapidly a cucumber will grow in an electrical hotbed than in an ordinary frame. It is pointed out that Norwegian and Swedish market gardeners and farmers produce lettuce and other market plants at out-of-season periods by this method. It is also useful in growing cantaloup melons and other expensive fruits at times when they are very dear. It is suggested that the electrical heating of the soil may prove useful for the growing of mushrooms, and would be a pleasanter method than the one ordinarily used. Experiments with this end in view could easily be carried on in a cupboard or a cellar. Orders have been issued under the provisions of the Horticultural Products Act imposing

duties on vegetables, fruits, and flowers. One of the effects of this order will be to keep out luxury products, and will give gardeners an opportunity of capturing a market which has hitherto been beyond their reach. There is now to be a duty of eight shillings per cwt. on all foreign lettuce from Jan. 1 until April 30. It is easy to compute the exact cost of the electric installation required; and where electricity is cheap, much can be said in its favour.

International Industrial Agreements

IN a general report on the economic aspects of international industrial agreements recently prepared for the Economic Committee of the League of Nations, it is concluded that international agreements constitute an important attempt to remedy certain disadvantages of the present economic evolution. They are not a panacea and do not apply to all products; they may mitigate but not abolish economic crises. Like other human institutions, they are liable to error and even abuse, but experience has shown that they quickly pay for any mistaken policy, and a false step may even imperil their existence. When of long duration, their interest definitely coincides with the general interest, for example, in stabilising at moderate prices, eliminating dumping, stabilisation of customs duties, and of employment, and in minimising the fall of wages in periods of depression. The advantages of lower costs to producers are secured in various ways, such as regular production, diminution and standardisation of stocks, elimination of unnecessary transport, economies and increased efficiency in research and other technical matters, patents, marketing, sales organisation. The advantages of greater equilibrium between production and consumption and of relative stability in prices are equally beneficial to producer and consumer. Agreements do not eliminate competition, but the limitations they impose on competition are beneficial, as avoiding waste or destruction of capital. The existence of international agreements did not create the present crisis; on the contrary, the seriousness of the crisis intensified the movement for such agreements to mitigate its consequences. They are accordingly considered to constitute a valuable guarantee of the economic and political stability of the nations.

North American Oyster Fisheries

MR. H. P. SHERWOOD who, during 1930, was sent by the English Ministry of Agriculture and Fisheries to investigate the American methods of oyster culture, in his paper "The Oyster Industry in North America: a Record of a Brief Tour of some of the Centres on the Atlantic and Pacific Coasts, and of a Summer in Canada" (*J. Conseil*, vol. 6, No. 3, Dec. 1931), gives an interesting account of the industry in North America and the various beds visited. He spent a summer in Canada, working on oyster investigations in Malpeque Bay, Prince Edward Island, and also visited most of the oyster-raising areas on both coasts of the United States. Recent figures put the annual yield of the oyster industry in North America at about 73,000 tons of food, valued at more than 14,000,000 dollars. The oysters belong to large and small companies and individual owners of oyster schooners, or oystermen, who fish in shallow reserved portions of the public beds. The natural beds of *Ostrea virginica* on the Atlantic coast at one time flourished from Maine to Mexico, but have greatly dwindled, and on the Pacific coast the industry is now practically confined to inlets in the State of Washington. Cultivation lies chiefly in providing in the summer clean shell cultch on the beds for attachment of the larvæ, culling or separating and sorting oysters from clusters in the clutch, and planting spat and half-grown oysters, together with measures for destroying pests. There is a demand for a greatly increased supply of seed oysters in many of the oyster-growing areas, although natural falls may in some seasons be very prolific. A few years ago this stimulated renewed interest in the problem of raising spat artificially, but more recently research has been directed to extending the possibilities of securing good sets of natural spat and to destroying pests, rather than to developing hatchery methods.

The Gulf Stream

THE results of investigations on the behaviour of the Gulf Stream were communicated to a recent meeting of the American Geographical Union at Washington by Mr. P. E. Church. According to Science Service, Mr. Church discovered many irregularities in width and temperature but no clear seasonal fluctuations. The data were obtained by recording instruments installed on commercial vessels crossing the triangle of waters between Halifax, Bermuda, and the Georgian coast. Inshore water extends to about the hundred-fathom line, beyond which is a wide area of cool water, ending in a narrow band of cold water believed to be due to upwelling from the depths. The Gulf Stream lies beyond, and was found to be 50 miles wide off Cape Hatteras and not more than 70 miles wide south of Nova Scotia. Outside the Gulf Stream to the south-east lies a broad area of warm water reaching towards mid-ocean. During the winter months, and occasionally at other seasons, the Gulf Stream flows as a double stream, with a tongue of cold water between, which may pinch off the northern stream and push the main stream considerably southward. Mr. Church does not explain this deviation, but doubts if wind action is the cause. South of Halifax the northern edge of the Gulf Stream averages a distance of 290 miles offshore but varies between 230 and 420 miles.

Science and the Empire

THE July number of *Discovery* is devoted, in view of the Ottawa Conference, to the subject of science and the Empire. Sir Stephen Tallents manages to give in a very few pages a vivid picture of the varied scientific activities which, on the confines of the Empire, become particularly associated with agriculture, the mainstay of dominions and colonies alike. The close contact maintained between scientific work at different centres is emphasised in this review and

illustrated by specific examples, and this practice is commended to the statesmen now gathered at Ottawa. The Right Hon. Lord Lugard explains the plan of the African Institute, with the financial support of the Rockefeller Foundation, to make a detailed study over a five-year period of the results of the impact of European civilisation upon the tribal system. Dr. H. V. Taylor, Commissioner of Horticulture to the Ministry of Agriculture, writes upon science and Empire fruit growing. The keynote of this article is that variation of climate, in the vast area covered by the Empire, prevents standardisation of methods, so that the grower is thrown into the hands of the research worker. Wool research in New Zealand and Empire air routes are other topics akin to the main theme which are also discussed.

Acquisitions of the Natural History Museum

A SERIES of microscope preparations showing all the early stages in the life history of the graptolite *Climacograptus* has been presented to the Department of Geology of the Natural History Museum by the Sedgwick Museum, Cambridge. The preparations were made by Mr. Ian Cox from material which he collected from rocks of Ordovician age in Akpatok Island, Ungava Bay, Northern Territory, Canada. Graptolites occur in the oldest fossiliferous rocks, and are organisms of unknown relationships, but generally supposed zoologically to resemble the living sea-firs, or sertularians—minute colonies of polyps encased in a horny skeleton. In the material from Akpatok Island, the original horny skeleton is preserved in a matrix of limestone, which can be dissolved and the skeleton extracted entire. The minutest structure and ornament of the early chambers, or thecæ, are visible, and the order and manner of budding of new thecæ can be clearly determined. Miss K. B. Macvicar has presented the extensive herbarium of her brother, Dr. Symers M. Macvicar, to the Department of Botany. Dr. Macvicar was the recognised British authority on Hepaticæ and was the author of the standard systematic account of them, "The Student's Handbook of British Hepatics". The herbarium is very rich in British and Continental species, and these are the more valuable because they are the basis of the descriptions and comparisons in the "Handbook". Dr. Macvicar was a medical man whose home was at Acharacle, Argyll, and in his travels in western Scotland accumulated an unrivalled representation of the flora, particularly of the less frequented parts of Argyll and Inverness. The herbarium contains about 18,000 specimens (that is, labels) and, as well as hepatics and flowering plants, contains mosses, seaweeds, and lichens. Mr. A. H. G. Alston, assistant keeper in the department, has just returned from western Greek Macedonia, where, in company with Mr. N. Y. Sandwith, of the Kew Herbarium, he spent six weeks. He collected about 1200 specimens, chiefly flowering plants. These are of interest because the area along the Albanian frontier has been visited previously only by a Czechoslovakian collector; moreover, the districts visited overlap to some extent those from which some plants were obtained by the department during the War.

Protection of the Fauna and Flora of Poland

IF one may judge by the size and quality of *Ochrona Przyrody* for 1931, the publication of the National Council for the Protection of Nature in Poland, a very vital interest is taken there in the preservation of natural amenities. The articles contain proposals for the formation of reserves for the primitive flora of the Dniester valley and elsewhere; but, perhaps because the position of some of the animals is more precarious, we turned to find out what measures were being discussed for their behoof. The opinion is held unanimously that the chase of the red deer of the Carpathians during the period of rut is harmful to the species and is responsible for the annual degeneration noticeable in the herds. But agreement is not reached as to the best means of meeting the difficulty. The majority hold as a distant ideal the desirability of suspending all hunting during the period of the rut, but since the custom is old-established and widespread, a gradual approach to the desirable end is suggested. An interesting paper by Wladyslaw Burzynski, the chief forester, discusses the position of the bear in the eastern Carpathians. The War was responsible for the slaughter of much of the breeding stock, so that even now the number probably does not exceed three hundred in an area of about 300,000 hectares. A third paper describes a visit to the workings and lodges of two colonies of beavers, one on the Szczara, the other on the Niemen.

Research and the Wheat Quota

SIR ALBERT HUMPHRIES, chairman of the National Institute of Agricultural Botany, in the course of his address to the annual meeting of the Institute's fellows at Cambridge on July 21 showed how agricultural research helps the farmer to make good use of the wheat quota. The quantity of wheat grown in Great Britain has been steadily diminishing and the proportion used for poultry has increased, so that in the past season home-grown wheat represented only some seven per cent of the national grist. The wheat quota is likely to raise this figure considerably, and the quality of English wheat for bread-making may come into its own again. The Cambridge Plant Breeding Institute has produced, and the National Institute of Agricultural Botany is now testing, a variety of which the quality is markedly superior even to Yeoman. Yielding capacity is, however, of first importance, and there are often differences of up to 20 per cent between varieties. The Institute in 1930–1931 tested, by methods which can detect much smaller differences, some hundred varieties, of which twenty are new ones not yet on the market. Sir Albert Humphries urged that facts of this sort show the Institute to be working directly for the improvement of the farmer's financial position.

Courtauld Institute of Biochemistry

THE Courtauld Institute of Biochemistry of the Middlesex Hospital Medical School was given by Mr. S. A. Courtauld because the services of this department to the Hospital had increased so greatly that it was impossible to house it in the Institute of

Pathology any longer. The Courtauld Institute was opened in June 1928; the building consists of five floors devoted to general biochemical research, and particularly to clinical biochemistry. In this department all the routine analyses of the Hospital are performed. At the opening, Mr. Courtauld endowed the chair of biochemistry to the extent of £20,000. Unlike most donors, however, he has realised the heavy cost of running such a department, and being anxious that it should continue to be used to the very best advantage, has generously given the Institute a further sum of £20,000.

Dr. Otto Struve

IT is announced in a Science Service bulletin for June 18 that Dr. Otto Struve succeeds Dr. E. B. Frost as director of the Yerkes Observatory. Dr. Struve represents the fourth generation of the Struve family that has made valuable contributions to astronomy. He is a great-grandson of Dr. F. G. W. Struve, who did pioneer work on double stars at Dorpat and Pulkova about a century ago. The latter was succeeded at Pulkova by his son Otto, who continued the work on double stars, and made a study of stellar distances and the solar motion. Both of Otto's sons carried on the family tradition, at Berlin and Dorpat respectively. His grandson, the new director of Yerkes, was born in Russia in 1897, and studied at the University of Kharkov. In 1921 he became an assistant in stellar spectroscopy at the University of Chicago, taking the degree of Ph.D. in 1923. He has been at Yerkes since 1924, being in succession instructor, professor, assistant director, and now director.

Announcements

THE Medical Research Council has awarded Dorothy Temple Cross fellowships for 1932–33 to the following: Veronica B. F. Dawkins, resident medical officer, Maltings Farm Sanatorium, Colchester; G. M. Dean, formerly of the Department of Surgery, University of Aberdeen; Evelyn M. Holmes, formerly assistant tuberculosis officer, Welsh National Memorial Association; J. N. O'Reilly, formerly house physician, Brompton Hospital, London; Dr. W. G. Scott-Brown, assistant surgeon, Throat, Nose, and Ear Department, Royal Free Hospital, London.

BY an Order of the Committee of Privy Council, made after consultation with the Medical Research Council and with the president of the Royal Society, Prof. A. E. Boycott, Graham professor of pathology at University College Hospital, London, and Prof. E. D. Adrian, Foulerton professor of the Royal Society and fellow of Trinity College, Cambridge, have been appointed members of the Medical Research Council, in succession to Prof. Robert Muir and Sir John Parsons, who retire in rotation on Sept. 30 after four years' service.

THE ninety-second meeting of the German Association of Men of Science and Physicians will take place at Wiesbaden and Mainz on Sept. 25-29. Applications for membership should be made to Prof. B. Rassow, Gustav-Adolf-Str. 12, Leipzig, C.1.

THE ninth vacation course in practical air photogrammetry will be held in the Mathematical Institute of the University of Jena on Oct. 10–22. The course will be exclusively in English, and will consist of lectures and practical work. The lectures will be given by Prof. Otto von Gruber, Prof. Hugershoff, and Dr. I. Tappen. The subjects to be dealt with include photographic apparatus and material, method of survey and navigation, plotting apparatus, and applications of air photogrammetry. Applications should be sent to Zeiss-Aerotopograph, Postfach 117, Jena, Helmholtzweg.

THE summer meeting of the Institution of Mechanical Engineers, under the presidency of Mr. William Taylor, will take the form of a visit to Canada and the United States on Aug. 19–Sept. 19. At the meeting, there will be a discussion on a paper read by Dr. F. A. Gaby on "The Generation and Distribution of Power under the Administration of the Hydro-Electric Power Commission of Ontario" and an address by Mr. C. L. Stevens on "The Point Plan of Rewarding Management and Labour". Many visits to works and power stations have been arranged. Further particulars can be obtained from the Secretary, Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1.

A JOINT autumn meeting of the Iron and Steel Institute and the Institute of Metals will be held at the Institution of Civil Engineers, Great George Street, S.W.1, and the Institution of Mechanical Engineers, Storey's Gate, S.W.1, on Sept. 12-15. A large number of papers will be presented at joint and separate sessions of the institutions. On Sept. 12, Dr. H. J. Gough will deliver the annual Autumn Lecture of the Institute of Metals on "Corrosion Fatigue in Metals". Among the excursions and visits to works are visits to the National Physical Laboratory, Teddington; the General Electric Company's Research Laboratories, Lamp and Glass Works, Wembley; the Mond Nickel Co., Ltd., Acton Refinery; and the Ford Motor Co., Ltd., Dagenham Works.

MR. F. EDWARDS, 83 High Street, Marylebone, has issued an important catalogue of books on America. It includes the rare first edition of Linschoten's "Discours of voyages into ye Easte and West Indies" (1598), John Calef's "Siege of Penobscot" (1781), Morton's "New English Canaan" (1637), Johnson's "Nova Britannia" (1609), and a fine copy of Sir Walter Raleigh's "Brevis et admiranda descriptio Regni Guianæ" (1599), as well as many other unusual items.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A lecturer in mathematics at the Chelsea Polytechnic, London, S.W.3—The Principal (Aug. 4). A research fellow in glass technology in the Department of Glass Technology at the University of Sheffield—The Secretary (Aug. 6). An assistant lecturer in physics at University College, Nottingham—The Registrar (Aug. 10). A lecturer in applied chemistry at the Northampton Polytechnic Institute, St. John Street, London, E.C.1—The Principal (Aug. 22). A technical assistant for special investigation work in connexion with wireless valves—Messrs. Lissen, Ltd., Worple Road, Isleworth.

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Nuclear Structure

THE experimental evidence for the existence of the neutron has given added support to the view [1] that the nucleus may be composed of protons, neutrons, and α-particles. Heisenberg [2] has recently found it convenient to use a model with protons and neutrons only as the building-stones. In various papers, Aston [3] has determined the isotopic constitution of many of the chemical elements, but it has not been possible to say, from considerations of stability, just what isotopes may be expected to occur. The purpose of this note is to point out regularities for elements of low mass, and to suggest a possible building-up principle for such elements.

Starting with an α-particle, let us add alternately a neutron and a proton. The resulting nuclei are He 5, Li 6, Li 7, Be 8, Be 9, B 10, B 11, C 12, C 13, N 14, N 15, and O 16. With the exception of He 5, these, and only these, have been observed for this mass range. With O 16, this type of regularity ends, which might be interpreted as due to the formation of some sort of a closed shell. To a first approximation, let us suppose the mutual interaction of the added neutrons and protons to be small compared with their interaction with the α-particle. Then, when a neutron and a proton are added, the resulting field will still favour a neutron over a proton. If an analogy with the external electronic system subsists, then the α-particle may represent a closed *s*-shell, with two neutrons and two protons, while O 16 is obtained by adding on a closed *p*-shell, with six neutrons and six protons.

The continuation of this process is the addition of a *d*-shell, with ten neutrons and ten protons. The stability conditions appear to be different, two neutrons being more stable in the central field than a neutron and a proton. The order of addition is as follows: neutron, neutron, proton, proton, and repeat. This results in O 17, O 18, F 19, Ne 20, Ne 21, Ne 22, Na 23, Mg 24, Mg 25, Mg 26, Al 27, Si 28, Si 29, Si 30, P 31, S 32, S 33, S 34, Cl 35, and A 36. With A 36, this shell becomes closed. These nuclei, and only these, have been found for this mass range, just as in the previous case.

If n denotes the total number of neutrons and protons together, then, except for $n = 3$, 5, and possibly 8, there exists an isotope for every value of n below 36, according to the experimental evidence. We should expect this to be a general property, holding for values of n greater than 36, also. In the range $36 < n < 64$, several points are missing, namely $n = 38$, 42, 43, 46, 47, 49, and 57. The corresponding isotopes probably exist in small quantities, but until they are found, it is rather difficult to determine stability conditions for this mass range. However, simple considerations lead to a prediction of certain isotopes. Since the neutron number for $n = 37$, 39, and 40 is 20, it might be expected to be the same for $n = 38$, giving A 38. Similarly, one can predict V 49, Mn 53, and Co 57. In this range $36 < n < 64$, which may correspond to an *f*-shell being completed, all the isotopes, except Cr 53, have even neutron numbers. This is so striking that one wonders whether or not the isotope reported for $n = 53$ is really due to chromium.

The analogy with the external electronic structure seems to indicate that for large values of n, conditions may become quite complicated. The experimental evidence bears this out. More information seems to be needed, however, before stability questions in general can be settled. Whether or not the α-particle plays a fundamental part remains to be seen, but we can certainly disregard it for the lighter elements, and consider protons and neutrons as being the elementary constituents.

Tidal Oscillations of Gravity

IN an earlier communication,[1] we reported the results of experiments to determine as exactly as possible the variations of gravity. We have now succeeded in increasing the accuracy and in eliminating the disturbances to such a degree that now the oscillations of gravity due to the attraction of the sun and the moon are directly perceptible in the photographic registrations. The arrangement of the apparatus is the same as stated in our previous letter.[2] The principal success was achieved by using the alloy *WT* 10 made by Krupp as material for the spiral spring. This material has an infinitesimal temperature coefficient of elasticity. By careful and repeated heating over a period of several months, it was also possible to reduce to a small factor the elastic after-effect. By this means the disturbances due to temperature are strongly suppressed, and also the uniform shift is very much diminished. The sensitiveness amounted

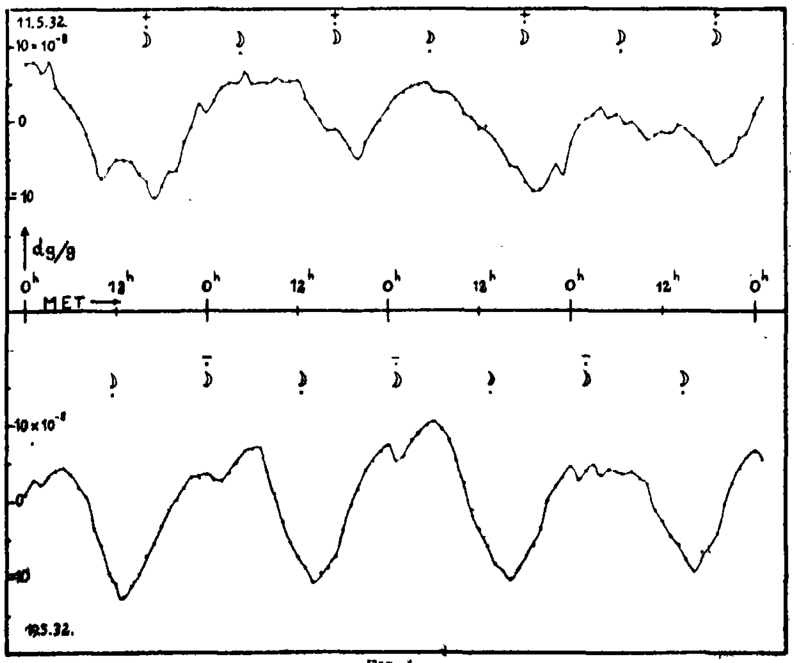

FIG. 1.

to a deflexion of 1 mm. for $dg/g = 10^{-8}$ at a distance of registration of 5 metres. With the aid of an electric method similar to the attracted disk electrometer of Lord Kelvin, the sensitiveness of the apparatus was often determined; therefore the indications of the registrations can be regarded as accurate to within $10^{-9}g$.

Fig. 1 shows an example of a record with no correction other than the elimination of the linear shift and the transformation of the readings to the same sensitiveness. Not only can the rough variation of gravity, especially due to the attraction of the moon, be seen,

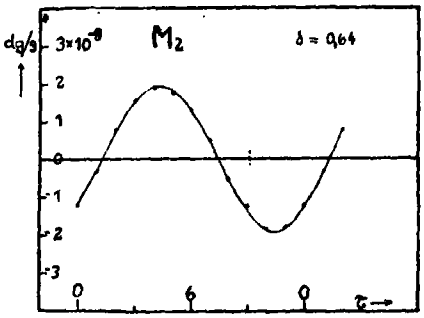

FIG. 2.

but also the finer features due to the alteration in the declination of the moon and in its position with regard to the sun. The transits of the moon over the meridian are marked (point above the sign is the upper transit); the sign + or − over the sign of the moon gives the declination of the moon on that day. In the upper part of Fig. 1 it can be seen how the influence of the moon, which had a positive (+) declination on those days, is at a maximum on its upper transit, producing at this time a pronounced minimum of gravity on the earth's surface. The lower part of Fig. 1 shows the greatest influence of the moon in the time of its lower transit, the declination of the moon being negative on those days. Since the gravimeter gives the vertical component of the alteration of gravity, the effect is the greater the smaller the distance of the celestial body from the zenith or nadir. With regard to the position of the moon relative to the sun, the upper curve corresponds to the neap tide, the lower curve to the tide of the full moon.

In consequence of these accurate and fairly well undisturbed records, the harmonic analysis of the curves gives very good results. The analysis of the term M_2 (period = 12·42 hours) was carried out as follows: the readings, after the elimination of the linear shift and after reduction to equal sensitiveness, were added for each 'hour' of the period and then divided by the number of periods. This gave for a time of about two months the curve shown in Fig. 2. Using the observations of one month altered the amplitude only by 2·5 per cent. This is in agreement with the corrections for short times of observations given by Börgen. We have also applied these corrections to the other terms of harmonic analysis. In this figure δ means the ratio of the observed amplitude to the expected amplitude, if the earth were perfectly rigid. The latter amplitude in Marburg is about $2{\cdot}97 \times 10^{-8}g$ for the mean time of the observations. In Fig. 2 the dotted line on the axis gives the expected position of the minimum, the full line gives the observed position. In the same way we have also obtained the terms O (25·82 hour period, amplitude expected for perfectly rigid earth $dg/g = 3{\cdot}1 \times 10^{-8}$) and even N (12·66 hour period, amplitude expected $dg/g = 0{\cdot}58 \times 10^{-8}$) in very good agreement, both in amplitude and in phase, with M_2. The term S_1, that is, the influence of the daily oscillations of the meteorological elements, appeared to be very small (if freed from the influence of K_1), especially compared with horizontal pendulum observations at the same depth (25 metres below surface-level).

The most significant result of the observations is, in the first place, that the observed amplitudes are *smaller* than the amplitude expected for a perfectly rigid earth, which seems to indicate a very much greater displacement of the surface than has been hitherto supposed. The second result is the displacement in phase of about three-quarters of an hour in the sense of a retardation of the maximum of variation of gravity. The ratio of amplitudes is for M_2 = 0·64, for O it is 0·74; this indicates an influence of the tides of the sea on the deformation of the solid earth, as is also observed in the experiments with horizontal pendulums. But this influence does not seem to suffice to explain the value of $\delta < 1$, which is in disagreement with the existing opinion.

Mechanism of Superconductivity

IT was often assumed that the transition from normal conductivity to superconductivity may be connected with a kind of 'spontaneous coupling' of the conduction electrons. Some authors were even inclined to identify this phenomenon with ferromagnetism. Although this extreme point of view seems to be very improbable, some analogies with ferromagnetism must surely appear if any kind of 'spontaneous coupling' between electrons is re-

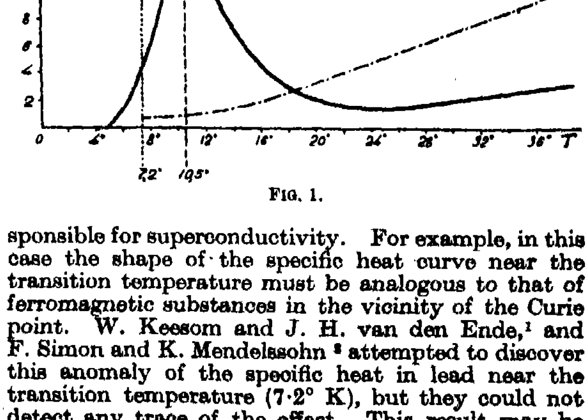

FIG. 1.

sponsible for superconductivity. For example, in this case the shape of the specific heat curve near the transition temperature must be analogous to that of ferromagnetic substances in the vicinity of the Curie point. W. Keesom and J. H. van den Ende,[1] and F. Simon and K. Mendelssohn[2] attempted to discover this anomaly of the specific heat in lead near the transition temperature (7·2° K), but they could not detect any trace of the effect. This result may be interpreted in two ways: either the hypothesis of the 'spontaneous coupling' of the conduction electrons in superconductors is completely wrong, or the number of the electrons which are concerned in conductivity is here so small in comparison with the number of

atoms that the specific heat anomaly of the conduction electrons cannot be detected with calorimetric methods.

As our measurements have shown, the specific heat anomaly of ferromagnetic bodies at the Curie point is so well pronounced in the thermoelectric effects (Thomson effect), that in spite of some difficulties concerning the sign of this effect, the order of magnitude of the specific heat anomaly can be computed from the purely thermoelectric constants in good agreement with calorimetric measurements. It is natural to try the same method in the domain of superconductivity. The recent investigations by J. Borelius, W. M. Keesom, C. H. Johansson, and J. O. Linde[3] of the thermoelectric force for lead and tin at the lowest temperatures permit us to compute the Thomson effect for these metals and to draw conclusions concerning the specific heat anomaly. Fig. 1 represents the Thomson coefficient for lead (as calculated from the experimental data) as a function of temperature. This curve is quite analogous to that of ferromagnetic substances, and it seems quite probable that it represents the general feature of the specific heat of the electrons concerned in the conductivity effects. It is not clear, however, why the temperature of the maximum of this specific heat curve (10·5° K) does not coincide with the transition point (7·2° K). Perhaps theory will be able to explain this discrepancy in the future.

From these results two important quantities may be calculated: first, ΔC_e (the height of the maximum of the specific heat curve), and secondly, ΔW_0 (the energy difference between the normal and the superconducting state at absolute zero), both for one electron.

	ΔC_e cal./degree.	ΔW_0 ergs.
Lead	8×10^{-25}	$1{\cdot}7 \times 10^{-17}$
Tin	$\sim 10^{-25}$	$\sim 0{\cdot}6 \times 10^{-17}$

If the number of the electrons was equal to the number of atoms of lead, the specific heat anomaly could certainly be detected, its numerical value being of the same order of magnitude as the normal specific heat itself. The precision of the calorimetric measurements permits us to determine the upper limit of the number of the electrons involved in the conductivity effects of lead. Actually it seems that the number of the conduction electrons is less than 1/200 of the number of the atoms in this case.

It is well known that magnetic fields destroy the superconductivity, the threshold value of the field H increasing as the temperature is lowered. By extrapolating the experimental data the value of H_0 may be found corresponding to absolute zero. We assume that the threshold value of the field is given by the condition that the magnetic energy of the electron $|\mu H_0|$ (where μ is the spin moment) is equal to ΔW_0.

$$|\mu H_0| = \Delta W_0 \qquad . \quad . \quad . \quad (1)$$

This assumption means that the superconductivity must be destroyed when the energy of the external forces exceeds the energy of the 'spontaneous coupling'. From (1) we may calculate H_0 for lead and tin, and compare them with the experimental results.

	H_0 expt. (gauss).	H_0 calc. (gauss).
Lead	2000-2500	2000
Tin	560	~ 700

According to the recent experiments of McLennan and his co-workers,[4] superconductors cease to be superconducting for high frequency currents if the frequency ν exceeds a certain threshold value. For tin at absolute zero, $\nu \sim 10^9$ may be found by extrapolation of the experimental data obtained at higher temperatures. It is interesting to notice that by assuming

$$h\nu_0 = \Delta W_0 = |\mu H_0| \qquad . \quad . \quad . \quad (2)$$

(where h is Planck's constant), we obtain for the same metal $\nu_0 = 1 \times 10^9$.

The remarkable coincidence between the observed and the computed data seem to support the general trend of the assumptions developed in this note. It is interesting to notice that the frequency of the Larmor precession corresponding to H_0 is equal to ν_0; thus the correlation between the two factors destroying the superconductivity may be found either on the lines of energetics or on the lines of the short time periods. Which of these interpretations corresponds to the real mechanism remains unsolved at this moment.

Application of Knudsen's Law to the Evaporation of Water

RECENTLY it has been shown[1] that the maximum rate of evaporation of liquid carbon tetrachloride measured experimentally agrees to within the error of experiment with that deduced from the Knudsen equation

$$m = 43{\cdot}75 \times 10^{-6} P \sqrt{\frac{M}{T}} \qquad . \quad . \quad (1)$$

In this equation, T is the temperature of the evaporating surface and P the saturated pressure of the vapour at that temperature, m is the mass in grams evaporating per second, and M the molecular weight of the liquid.

In the case of water, however, the experimental rate of evaporation was found to be only from 1 to 2 per cent of that given by equation (1), and the discrepancy was ascribed to reflection of vapour molecules at the surface of the liquid.[2]

It will be seen from equation (1) that, in order to calculate the mass evaporating per second, it is necessary to know the surface temperature and the vapour pressure at this temperature. In the case of poorly conducting liquids, the surface temperature will be considerably below that of the liquid in bulk (20°-30° C. for water at 25° C.), and in the above-mentioned experiments it was measured by means of a thermocouple immersed in the liquid. As the latter evaporated, the thermocouple passed through the surface and so gave an estimate of the surface temperature. It is clear, however, that any instrument introduced into the liquid in this manner will give only an approximation to the surface temperature, since it actually measures the mean temperature of a thin layer near the surface. This average temperature will necessarily be higher than that of the true surface layer at which rapid evaporation is taking place. Hence the true value of T in (1) must be smaller than that given by the thermocouple, and it thus remained possible that, if more accurate values of T and P were obtained, the rate of evaporation deduced from equation (1) would agree with the experimental rate and the assumption of reflection would be rendered unnecessary.

It is hoped, however, that this possibility has been

eliminated in a new experiment in which the temperature of the surface has been deduced from measurements of the surface tension of the evaporating liquid. As this surface tension must be controlled chiefly by the temperature of the outermost liquid layers, a very close approximation to the true value of the surface temperature should be obtainable in this way.

As was to be expected, the surface temperature so measured was lower than that recorded by the thermocouple, so that the ratio (f) of the experimental to the theoretical rate of evaporation was somewhat greater than before. The difference was, however, not very marked. Whereas the surface temperature measured by the thermocouple gave values of 'f' ranging from 1 to 2 per cent, those deduced from the surface tension measurements gave values between 3·5 and 4·5 per cent.

The experiments therefore indicate that when the temperature of the actual evaporating surface layer is measured as accurately as possible, there is still a very considerable discrepancy between the theoretical and experimental rates of evaporation of water. This would seem to confirm the earlier suggestion that not all the vapour molecules striking the liquid surface are able to enter.

A detailed account of these experiments will be published shortly.

Proper Name of the Amœba

PROF. T. D. A. COCKERELL concludes his letter in NATURE of May 14, p. 726, on this subject, by the question: "What, then, is the proper name of the common amœba?" While we are awaiting the decision of the systematists, I should like to make some relevant remarks.

In 1916, Schaeffer classified those rhizopods which had the characteristics of Leidy's *Amœba proteus* into three species. Later, in his monograph on the "Taxonomy of the Amebas" (1926), he raised them to the rank of genera. Mast and Johnson (*Archiv für Protistenkunde*, 1931), in the paper that provoked Prof. Cockerell's letter, would reduce these three genera to the status of mere varieties. *Amœba discoides* (*Metachaos discoides*) has never been recorded in Scotland, so I cannot make any statement about the validity of its specific value, but in my long experience of the other two large amœbæ, so generally employed for class purposes, I should like to affirm that, in my opinion, Schaeffer rendered a real service when he cleared up these differences amongst the rhizopods commonly called by Leidy's name *Amœba proteus*. Confusion between the species to which he (Schaeffer) in 1916 applied the names *Amœba proteus* and *Amœba dubia* respectively had been responsible before that time for retarding progress in our knowledge of these animals.

Since 1916, other information has been forthcoming, all of which goes to support Schaeffer's contention that at least two distinct organisms had been confused under Leidy's name *Amœba proteus*. We now have a fuller knowledge of the life-history of one of these forms, namely, *Amœba proteus* (*Chaos diffluens*), and of the details of its nucleus (in development as well as in the adult state). These latter differ markedly from the corresponding details of *Amœba dubia*. Prof. Chambers finds that the cytoplasm of *Amœba dubia* is more suitable for micro-injection experiments than that of *Amœba proteus*, which seems to point to a fundamental difference in the cytoplasm of the two species. In short, the same specific name cannot be applied to them without resulting confusion.

There are of course well-marked varieties of *Amœba proteus* (*Chaos diffluens*). One variant, owing to an almost entire absence of crystals, is peculiarly translucent; it was the subject of much discussion at the Glasgow meeting of the British Association (1928). Other varieties due to size of nutritive spheres, etc., are also known. There is also a great variety in size (volume) in different strains of *Amœba proteus* cultivated under different conditions of food supply and temperature.

In discussing the contrasts in behaviour between Rösel's "kleine Proteus" and Leidy's *Amœba proteus*, Mast and Johnson state that they have never known any tendency of the latter to aggregate on the sides of the vessel. As a matter of fact, this condition is easily brought about in *Amœba proteus* (*Chaos diffluens*) by altering the food in the culture. This species is very fond of a diet of rotifers. Now, *Rotifer vulgaris* tends to form little clusters of individuals on the sides of the vessel. The amœbæ creep up after them, sometimes forming a beautiful carpet of individuals on the sides of the vessel containing the culture. Amœbæ also like encysted flagellates. These aggregate in the surface vegetable scum which often collects in cultures of amœbæ. In this 'scum' the agamonts produce agametes, as may easily be proved by skimming off a small quantity for inoculation into a new medium, when the young amœbæ may be seen hatching out of the cysts.

In my experience, isolated examples of *Amœba proteus* (*Chaos diffluens*) as well as of *Pelomyxa carolinensis* often develop the yellowish tinge referred to by Mast and Johnson—not, however, as they suggest, due directly to the colour of the food organisms present in the food vacuoles. I have always attributed this appearance in *Amœba proteus* rather to unfavourable environmental conditions. The same effect may be produced by slight lowering of the hydrogen ion concentration of the surrounding water. If the pH be not corrected, the specimens showing this yellowish tinge die off. Such facts should not be ignored when discussing the systematic position of Rösel's "kleine Proteus".

Pelomyxa carolinensis in Great Britain

CONSIDERABLE interest is attached to the name of the common large free-living amœba (*Amœba proteus*, Leidy) used extensively for teaching purposes. In recent discussions by systematists on this point, an organism known as *Pelomyxa carolinensis* plays an important part. This animal was renamed by Schaeffer (1926) *Chaos chaos*. Mast and Johnson (1931), quoting Schaeffer, say it has never been reported from Europe.

As I am at present engaged in a research on this animal, I should like to state that I have several records of its occurrence in the British Isles.

I am indebted to Sister Bernardine (Dr. Lucy Carter) for lending me some unpublished drawings of this species made by her from specimens obtained in Birmingham, Killarney, and the River Auchter (near Wishaw, Scotland), and to Sister Monica Taylor for records of its occurrence in the small pools along the shores of the head of Loch Fyne and in a tributary of the Allander River (Scotland). I myself at present am obtaining supplies from Loch Tannoch.

The specimens are smaller than those measured by Wilson (1900), as were those studied by Kepner and Edwards (1917), but the environmental conditions of the material I am collecting are almost identical with those described by Wilson.

ISABELLE P. MCGUIRE.

Shepparton, Milngavie.

The Whale Shark, *Rhineodon typus*, among the Seychelles Islands

THE publication in a recent number of *Science* of notes[1] on the occurrence of the whale shark in Bornean waters and on the Florida coast has led me to look over my notes and to put on record its occurrence and abundance in the Seychelles.

About six hundred miles north-east of Madagascar and four degrees south of the equator is found the Seychelles archipelago, formerly a French dependency, but now a British colony. To these islands, in 1868, came an Irish naturalist, E. Perceval Wright, for a six months' stay. To him we owe our first knowledge (and only published accounts) of the occurrence of the whale shark in this locality, where it is called the 'Chagrin'. He took photographs of two specimens (male and female), dissected two fish, and saw a number of others in the waters around the islands. It is greatly to be deplored that Wright made so little use of his opportunities to study this great fish. He wrote no article on it, nor did he publish his photographs (presumably the first ever made of the whale shark). Brief accounts, however, are given incidentally in four of his publications, in none of the titles of which does the name of the shark occur. There is nothing to form a guide, and only by running down obscure clues did I find accounts of the whale shark in the works listed below.[2]

The whale shark is as abundant around the Seychelles to-day as it was in 1868. In 1914 Dr. A. G. Mayor, director of the marine biological work of the Carnegie Institution of Washington, planned to send me to the Seychelles to study *Rhineodon*. Seeking information, I got in touch with Mr. P. R. Dupont, curator of the botanic station on Mahé, who informed me then, in 1919, and again in 1925, that the fish was comparatively common in the Seychelles. He had this information from many fishermen, and the managing director of the St. Abbs Whaling Company, situated on Mahé Island, also told him that the whale shark was abundant on the Seychelles Bank. Moreover, Mr. Dupont himself had at various times seen specimens, to the number of five or six. He further ascertained from an old fisherman that about 1865 there had been carried on by a family, of whom he was the only living member, a fishery for the 'Chagrin' to obtain oil from its liver. This man named eleven "grounds" where the fishing had been carried on, and said that when he was a boy of fifteen at Frigate Island the 'Chagrin' could be found all the year round. Mr. Dupont adds that to-day it is almost always to be found there in calm weather.

The War made the trip to the Seychelles impossible, so it was October 1919 when I again heard from Mr. Dupont. He reported that whale sharks were comparatively plentiful around the south end of Mahé Island, where a number had been seen a few days previously. As a result of this information, tentative plans were again made to go to the Seychelles, but the untimely death of Dr. Mayor in 1922 put an end to these.

In the meantime Mr. Dupont, who had been severely wounded in the War, was transferred to Mauritius, but returned to the Seychelles in 1924. Under date of July 27, 1925, he wrote me that *Rhineodon* was still not uncommon, and added:

> "According to our local fishermen, *Rhineodon* comes over to the Seychelles when *Caranx gymnostothoides* appears in enormous shoals from May to August, during the trades which blow heavily from the S. of Java toward the N. end of Madagascar, bringing on their way a good deal of fish to our archipelago. Advantage no doubt is taken by migratory fish of the currents which run in the same direction at this time."

Here then we have a suggestion as to how the whale shark has reached the Seychelles. This will become more apparent when one learns that *Rhineodon* is found in numbers in the East Indies and especially around Java. The abundance of the whale shark at the time of the schooling of the *Caranx* is not because the former feeds on the latter, but because both feed on a certain small sardine called 'tauve' and upon a little octopus called 'vauve', which abound in vast schools. In fact, the fishermen are guided by the presence of the 'Chagrin' to indicate good fishing grounds for *Caranx*. As to the breeding of *Rhineodon* in the Seychelles, the fishermen were in doubt, but Mr. Dupont definitely says that "The breeding season occurs in June". From this and from the statement that the fish is found all the year round, we may judge that, while it may have originally come from the East Indies long ago, it is now native to the Seychelles.

In my last letter to Mr. Dupont (September 1925), I asked him for any data that might have recently come to hand, and stated that I would like to bring together and publish that which he had sent me. Having had no answer, I fear that he has succumbed to his wounds. So the data about *Rhineodon* in the Seychelles have been collected and are now published in order to put the facts on record and to give Mr. Dupont credit for the information which he so kindly gathered and communicated.

Light and Sexual Periodicity in Indian Buffaloes

DR. MARSHALL has stated[1] that "in tropical countries where environmental conditions are similar throughout the year, such as the Cameroons, the native birds have no restricted breeding season but breed at any time". The data I collected in 1929 with regard to the buffaloes is of interest in this connexion.

The Government of Madras has stationed two buffalo bulls for stud purposes at the Agricultural Research Station, Kovilpatti (lat. 9° N.). During 1926–29 I noticed that a greater number of buffalo cows were brought to service in particular weeks of the months, which suggested that there was some periodicity in these animals coming on heat. The prevailing opinion amongst cattlemen was that more animals came on heat during periods of dark nights. With the aid of Tamil almanacs, I worked out a frequency curve of the services by these bulls during the previous ten years with respect to the new moon and full moon days occurring in each month. It was interesting to note (Fig. 1) two modes in the curve,

the higher falling on the new moon day and the smaller on the full moon day. This clearly indicated that the position of the moon would also influence

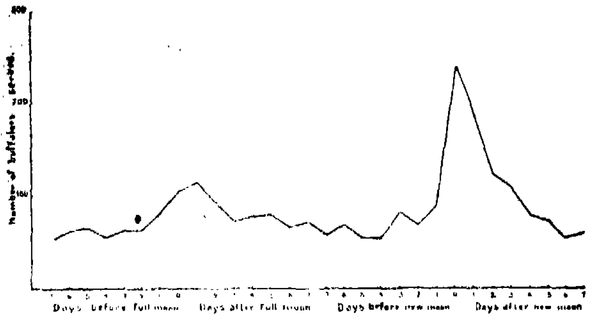

FIG. 1.

the onset of œstrum in buffaloes, if the buffalo cows brought to service could be taken as random samples of the buffalo population of the tract. When these data were retabulated according to the calendar months, a seasonal variation was also apparent.

	No. of Animals served.	Length of Nights on 1st of each Month.
January . . .	287	12 hr. 58 min.
February . . .	250	12 27
March . . .	248	12 13
April . . .	204	11 54
May . . .	218	11 36
June . . .	167	11 24
July . . .	169	11 21
August . . .	156	11 31
September . .	132	11 46
October . . .	155	12 5
November . .	199	12 23
December . .	272	12 36
Total . .	2457	..

It would appear from the above grouping that there exists an association between the length of nights and the number of œstrous animals. But when these figures were compared with the agricultural seasons of the year, it was found that the variations were more closely related to the availability of fresh grass than to the length of nights.

Further Purification of Gonadotropic Hormones (ρ-Factors)

DURING the past six months a further advance has been made in the purification of the gonadotropic hormones (ρ-factors, prolans) based on methods previously described, in particular the observation [1] that certain coloured hormone solutions can be selectively filtered in such a way that the filtrate is strongly coloured, although possessing extremely low gonadotropic activity compared with that of the original solution. The filters most useful for this purpose were the 'ultrafein', 'mittel', and 'fein' filters supplied by the Membranfilter Gesellschaft of Göttingen; the first allows rather more rapid filtration, but is somewhat more porous to the active ρ-factors.

A solution of 2 gm. of ρ-factors (20,000 units per gm.) in 100 c.c. of distilled water is adjusted to about pH 7·2 and concentrated to about 10 c.c. by filtration. The residue is washed on the filters with successive portions of distilled water, and finally washed carefully off the filter and centrifuged to remove a small amount of insoluble matter. The solution (20 c.c.) is then treated with 100 c.c. of absolute alcohol plus 100 c.c. of ether. The flocculent precipitate is removed by centrifugation, washed with alcohol and ether, and dried. The yield is usually about 0·15-0·2 gm., and the activity is increased to 200,000 units per gm., provided that the washing on the filter has been sufficient. The process described takes about 8 hours up to the alcohol-ether precipitation, using two filters of 5 cm. effective diameter, but is a very trustworthy one for the preparation of small quantities of a highly active salt-free product.

In the absence of inorganic salts (as in this preparation) the ρ-factors cannot be precipitated from aqueous solution by alcohol alone, and further addition of ether is necessary.

This highly active product contains no sulphur, phosphorus, or halogen, and has a nitrogen content of about 8·4 per cent (9·1 per cent on an ash-free basis). Further, it does not give the ninhydrin reaction for α-amino acids until hydrolysed by dilute mineral acids, although it is inactivated by heating in neutral solution at 100° for half an hour. From these facts it would appear that the active principles are nitrogen-containing compounds, probably polypeptide in character, as has been previously postulated, [1, 2] although, in view of their thermolabile nature, one may be dealing with a case of adsorption.

Eradication of Slugs and Snails

IN the note on the "Eradication of Slugs and Snails" in NATURE of July 16, p. 90, reference is made to many of the accepted methods of dealing with these pests. The trouble with barriers of repellent material is that spreading plants such as violas, certain asters, carnations, etc., are difficult to surround without injurious contact to the foliage, and the slugs live amongst the roots. They appear, moreover, to prefer the flowers and foliage of these plants to the baits variously used, and extensive trials this spring with orange skins, bran, and bran mixed with Paris green were entirely ineffective. Examination after dark showed that each viola plant or carnation had as many as forty or fifty small white slugs feeding on it. As hand-picking was out of the question, a small pot containing a very strong solution of salt and permanganate of potash was carried, and each slug was touched with a knitting needle dipped in this solution. Half an hour spent each evening of one week has almost removed the trouble. I am not sure whether a solution of permanganate of potash without salt would be equally effective, and less harmful to the foliage if it touched it, but a single crystal of this salt will quickly kill a large snail. It is, however, not difficult to avoid damage to the foliage. For small upstanding plants, such as zinnia and dahlia seedlings, a collar of sheet zinc about one inch high is an absolute deterrent, and does not require renewal.

Research Items

Anthropology of Carpathian Ruthenia.—A study of the racial characters of the Ruthenian inhabitants of the upland valleys of the Carpathians has been made by Prof. V. Suk, of which a preliminary report has been published (No. 150, *Pub. Fac. Sci. Univ. Masaryk*). The native Sclavonic population lives in long narrow villages which often extend for several miles along the deep valleys of the mountains. They fall into two groups, between which there are considerable cultural differences. They speak the same language but with dialectical variation. The Huculs, the eastern group, have dark hair, eyes, and skin, and are of tall stature, averaging five feet eight to nine inches, many men reaching six feet. The head is brachycephalic (av. index 84). Dinaric faces are not rare; but these have green-blue or dark blue eyes. Other members of this population have features approaching the Alpine; but the average complexion is darker than is usual in 'alpine' countries. On the whole, they are healthy. Tuberculosis is rare; but goitre is common. The western group, known by different names locally, is much poorer and of lower status. The skin is lighter than in the east and at times shows a yellowish tinge. The eyes are brown, green-brown, and blue, the latter usually with brown hair of the lighter shades. The stature is lower and the Dinaric face is absent, but faces of Laplander type are common. There is also a number of indeterminate types, some of which approach the 'alpine' type, though with lighter complexions. The people are much less healthy than the Huculs. Tuberculosis is common, in some villages rising so high as forty per cent among the children. Adults without goitre are rarely seen.

Ancient Jewelry from Yasin. — Sir Aurel Stein figures and describes in the *Indian Antiquary* for June a collection of ancient jewelry from the once cultivated tract of the Dasht-i-Tana in the Hindu Kush valley of Yasin in the Gilgit Agency. The find was made by villagers while digging up a small mound, and no particulars of the circumstances are available. As most of the objects were of gold, it is probable that 'specimens' only were given up. Comparison with objects cleared from burial deposits in 1913 suggests a similar provenance. Of the Yasin objects, two provide more definite chronological evidence than those found elsewhere. Of these two objects, one is a small bronze figure of a Bhodisattva 3¼ inches high and 2¼ inches broad at the base. The figure is seated and the right hand is held, palm outwards, at the level of the knee, while the left holds some indistinguishable object. The metal is too corroded to allow details of features or dress to be made out; but around the neck is an ornamental band or chain and the folds of the drapery are disposed in the Græco-Buddhist style of Gandhāra. The lotus seat is of a style which persists in Buddhist sculpture from the early centuries of our era down to a late period. This little figure may be an import from outside, as is certainly the second object, an intaglio set in the bezel of a fine gold ring. It is cut in an onyx-like stone, much crackled by exposure to great heat. It represents a helmeted male head which is of a late Hellenistic or Roman style of workmanship. Similar intaglios from Khotan and other parts of Chinese Turkestan have been dated at second-third century A.D. The number of such seal stones found in Central Asia and north-west India suggests that they were a frequent article of import from the west.

Birds of Guatemala.—The bird-life of this limited area, lying between two distinct zoogeographical regions, the nearctic and the neotropical, is wonderfully rich in racial forms. The American Museum of Natural History possesses collections of birds made there by Austin Paul Smith and A. W. Anthony, excelled only by the Salvin-Godman collection in the British Museum, and these collections have been reported upon by Ludlow Griscom in a monograph of 439 pages (*Bull. Amer. Mus. Nat. Hist.*, vol. 64, 1932). The wealth of the bird-life of the area is traceable to a number of factors, of which the chief are the antiquity of the country and its position between the two zoogeographical regions of the New World. To the first is due the survival of some elements of a once rich pre-glacial avifauna; to the second the influx of fresh contingents of birds from the north during the Pleistocene period, and of southern tropical elements during post-glacial time. These various elements in the bird-life have been so modified by time, in association with diverse topography, much local isolation, and half a dozen different climates, as to produce the 736 species and subspecies recorded in this monograph. The author, refusing to commit himself, leaves the reader to decide whether the compelling factors in this evolution were the latent potencies in the germ plasm or the stresses of time and change of environment, but he reminds us that the outcome of systematic and zoogeographical studies has been to show that, granted variation is limited by the latent potencies in the germ plasm, such potencies are of no value with the great majority of birds unless subjected to environmental stresses. Where environmental stresses are many and diverse, there is extraordinary diversity in the bird fauna, as in Guatemala or in Colombia or Ecuador; where environmental stresses are few or too severe, there is a relatively uniform and poverty-stricken bird fauna, as in New England, which is just recovering from the glacial epoch.

Free-living Nematodes of the Belgian Coast.—This, the first account of the free-living nematodes of the Belgian coast, is based on the collections in the Natural History Museum in Brussels and on material collected by dredge or net from twelve stations. The authors (J. H. S. Stekhoven, jr., and W. Adam, in *Mém. Mus Roy. d'Hist. Nat. de Belgique*, No. 49; 1931) direct particular attention to the material from the surface of *Alcyonium* and from oyster beds. The colonies of *Alcyonium* dredged at two of the stations were covered with a rather thick layer of fibrous substance (probably the mucus coagulated on fixation), on the inner surface of which nematodes were present in large numbers and in almost identical proportions in both cases. Oyster beds are favourable for those nematodes which are detritus feeders, and a ship's hull with its rich fauna of hydroids afforded excellent conditions for an opulent nematode fauna. Twenty-six genera, including twenty-seven species, eight of which are new, are recorded. The geographical distribution of each species is stated, and notes on the characters, including the Cobb formula, are given for most of them. While these nematodes are essentially marine, some of the species are capable of penetrating into waters of lower salinity.

Mosaic Disease of the Bean.—"Investigations in the Mosaic Disease of Bean (*Phaseolus vulgaris* L)", by Ray Nelson (*Michigan State College Tech. Bull.*, No. 118; 1932), gives the results of very extensive studies

into the behaviour of the virus diseases of the runner bean. The malady known as mosaic has a world-wide distribution, and is one of the few viruses which are transmitted through the seed. Many aspects of the problem have been studied, but great efforts were directed towards cultivating the virus or finding a causal parasite. A coccoid body was isolated from diseased tissue and appeared to have a close association with mosaic, but would not reproduce this disease when inoculated on to healthy plants. Rugose mosaic, a virus disease distinct from ordinary mosaic, has also been studied.

Geology of South-Eastern Manitoba.—*Memoir* 169 of the Geological Survey of Canada, by J. F. Wright (1932, pp. 150 and map), is devoted to the geology and mineral deposits of the area between the south end of Lake Winnipeg and the Lake of the Woods, just east of the junction of the Canadian Shield with the Great Plains. Apart from Quaternary deposits and the nearly horizontal early Palæozoic strata which overlap the crystalline complex of the Shield, the rocks are of ancient Pre-Cambrian age, and consist (*a*) of an assemblage of sedimentary and volcanic strata and their metamorphic equivalents intruded upon by (*b*) a widespread series of igneous rocks ranging from peridotite to granite. The supercrustal assemblage is known as the Rice Lake Series, and is divisible into the Manigotagan phase of sedimentation (fine-grained arenaceous and argillaceous deposits); the Beresford Lake phase of volcanic conditions (basalt, andesite, dacite, and rhyolite, now largely altered to green-schists, with greywackes, chert, and iron-bearing formations); and the Wanipigow phase of renewed sedimentation (greywacke, arkose, quartzite, and slate). The series is typical of geosynclinal conditions and is lithologically similar to the Couchiching and Keewatin. The deep-seated intrusives include peridotite and gabbro, associated with nickel-copper sulphides, and both are known to be earlier than the granodiorites and granites. The end phases of granite invasion are represented by microcline- and albite-pegmatites. Tin and lithium deposits occur with the latter, and one of the albite-pegmatites contains uraninite, which H. V. Ellsworth finds to have a lead-ratio of 0·260 to 0·265 (*Amer. Min.*, 1931, p. 569). This is the oldest mineral yet known, and it is of interest that the conglomerates of the Rice Lake Series contain pebbles of a still older granite.

Cavities in the New Jersey Traps.—The crysta cavities in the Triassic trap rocks of the New Jersey zeolite region have long excited the interest of mineralogists. A detailed study of the phenomena has been made by W. T. Schaller (*Bull.* 832, U.S. Geological Survey, 1932, pp. 90). The cavities occur in an altered basalt that as lava flowed into pre-existing lakes occupying depressed areas in which glauberite and other saline minerals had accumulated. Where the lava poured over dry Triassic shale it contains no cavities. The mineral history is as follows: (1) Solidification of basalt; (2) formation of anhydrite and glauberite derived from the lake waters; (3) formation of quartz, albite, etc., replacing the lava; (4) solution of glauberite leaving *rhombic cavities*, precipitation of prehnite, datolite, pectolite, etc., and solution of anhydrite leaving *rectangular cavities*; (5) zeolite formation from lime and soda supplied by the solution of the saline minerals; (6) deposition of calcite and changing of remaining anhydrite to gypsum and thaumasite. In addition to the two main types of cavities mentioned above, there are also lamellar types representing anhydrite and possibly calcite and babingtonite, and a miscellaneous series after apophyllite, quartz, calcite, natrolite, pectolite, and other minerals. Although no glauberite now remains in the region, the rhombic cavities sometimes contain pseudomorphs in quartz the measured forms of which prove to be identical with those of glauberite.

Rainfall of Sumatra.—Dr. J. Boerema has published detailed monthly and annual maps of the rainfall of Java and Madura (*K. Mag. Met. Obs. Batavia*, Verhand. 14, vol. 2). Similar information is now available for Sumatra (Verhand. 24, vol. 2). The figures relating to rainfall are derived from observations extending over at least five of the fifty years 1879–1928. In a few instances they refer to the whole fifty years. Anyone making use of these statistics should bear in mind the great difficulty of securing accurate and comparable figures from a large number of voluntary observers, and should also note that figures based on periods of varying length are not strictly intercomparable, even if free from error, owing to differences in the general character of the weather in the different periods—the 'errors of sampling' of mathematical statistics. In spite of these difficulties, the material is obviously of great economic importance, besides being a big contribution to climatology. Sumatra is famous for its luxuriant vegetation. Except on the higher mountains, the mean temperature of every month is high, and bearing this fact in mind, an inspection of the rainfall statistics provides a sufficient explanation of this luxuriance. It is significant that on the map of annual rainfall no tint is provided to represent a rainfall anywhere near so low as London's 600 odd millimetres. On a part of the mountain chain that lies not far from Padang, on the west coast, the annual total is shown as more than 7000 mm. (23 ft.), and there is an almost equally wet region towards the north end of the island. If more detailed information is required, the reader must refer to Verhand. No. 24, vol. 1, which contains tables of rainfall relating to 3293 stations in the Netherlands Indies, for the period 1879–1928 or a portion of that period. This volume includes the data for Sumatra.

Thermal Expansion of Bismuth.—An investigation of the thermal expansion of a bismuth single crystal has been made by A. Goetz and R. C. Hergenrother (*Phys. Rev.*, June 1), which is of importance in bringing out the difference between the macroscopic and microscopic properties of solids. The expansion was measured by two methods. The first, which has been carried out several times for this substance, was similar to the standard macroscopic work of Roberts. The second consisted in examining the temperature shift of an X-ray beam, when reflected from the (111) plane in a modified Siegbahn apparatus, and tells how the crystal lattice changes in size with change in temperature. The results of the latter determinations show that an empirical relation, due to Grüneisen, which states that expansion coefficient and specific heat bear a constant ratio to one another, was accurately satisfied up to almost the melting point, whereas a departure from this, outside the range of experimental error, occurs if the macroscopic expansion coefficients are used. The interpretation of the discrepancy, based on the assumption that there is an amorphous component in the crystal as well as the component with a regular lattice, is that the relative amount of the former increases with increase in temperature, but little, if any, obvious advance has even now been made towards the outstanding problem of why a pure substance melts sharply.

Stellar Structure.—A review of the recent work of the constitution of the stars was given by Prof. E. A.

Milne in a lecture on "Some Aspects of Stellar Structure", delivered before a joint meeting of the University of Durham Philosophical Society and the Newcastle-upon-Tyne Astronomical Society on March 4, an abstract of which has just been published (*Proc. Univ. Durham Phil. Soc.*, vol. 9, pt. 1). The lecture gives a descriptive account of the properties of the 'two phase' stellar model and the conclusions to be drawn from them. This model consists of a degenerate spherical core, approximately isothermal, surrounded by a gaseous envelope of constant opacity. The essential variables taken are L/M, the ratio of the luminosity of the configuration to its mass, and r_1/r_2, the ratio of the core radius to that of the whole configuration. The relations between these two variables, as worked out mathematically, are exhibited as a series of curves connecting L/M with r_1/r_2 for each constant M. The curves show that for certain values of L/M and constant M there are two distinct configurations possible, corresponding generally with the phenomenon of the rearranged 'Russell diagram'. Certain of the curves of high mass show a position where dL/dr_1 is infinite. This is the limiting position giving a maximum L for that particular mass. It is shown that at this point the core radius is indefinite and pulsations are likely to occur, suggesting an explanation of the cepheid variables, which thus appear only in certain classes of configurations. The curves also exhibit the possibility of discontinuous changes. During one of these the core radius increases cataclysmically and the external radius decreases cataclysmically, with the consequent evolution of energy. The phenomena resemble those of a nova outburst. The curves of low mass and certain portions of those of high mass yield an approximately linear relation between L/M and M for corresponding configurations. They also throw light upon the giantism of some stars, the dense characters of the nuclei of planetary nebulæ, and the general relationship of dense stars to non-dense stars. The complete mathematical investigation has since appeared in *Mon. Not. R.A.S.*, vol. 92, No. 7.

Oxidations with Selenium Dioxide.—Riley, Morley, and Friend (*J. Chem. Soc.*, June) show that selenium dioxide is capable of oxidising acetone to methylglyoxal and acetophenone to phenylglyoxal on heating, the selenium dioxide being reduced to selenium. Similar reactions giving other derivatives of glyoxal were carried out. A methylene group adjacent to the carbonyl group of an aldehyde is readily oxidised to carbonyl by selenium dioxide and the preparation of glyoxal from acetaldehyde according to the reaction

$$CH_3CHO + SeO_2 = (CHO)_2 + H_2O + Se$$

may be caused to proceed almost quantitatively. In some cases the reaction may be carried out by passing the vapour of the substance over selenium dioxide in a heated tube. The reactions show that selenium dioxide has a specific oxidising action on aldehydes and ketones of various types, whereby 1 : 2 diketones and aldoketones are conveniently obtained in quantity, compounds which contain a methylene group activated by proximity to a negative group being specifically oxidised at reasonably low temperatures.

Astronomical Topics

A New Algol-Variable in Andromeda.—*Astr. Nach.* 5877 contains a paper on this star by its discoverer, Herr K. Lassovszky. He found it on a plate that he took at Neubabelsberg on April 27, 1931; its position for the equinox of 1855 is $23^h\ 42^m\ 18^s$, N. Decl. 44° 58·4′, and its designation 381, 1931 Andromeda. He took a series of plates on fifteen nights between July 23 and Aug. 21, 1931, to study the light curve; the period is $0{\cdot}79365^d$ or about 19 hours. The magnitude is 11·26 at maximum, and falls to 11·87 at minimum; the duration of eclipse is $0{\cdot}160^d$; the light-curve appears pointed at minimum, showing that the eclipses are not annular, as in that case the curve is flat at minimum. The observations do not show any trace of a secondary minimum, such as occurs in Algol; it may be concluded that the eclipsing star is much fainter than the other. The star is less than 2° distant from "Selected Area No. 43"; Herr Lassovszky utilised this fact to obtain the magnitudes of his comparison stars by comparing them with stars in that well-surveyed region. It reflects credit on a single observer to have both discovered the star's variability and deduced an accurate light-curve in the course of a year.

Astronomical Notes for August.—Mercury is well placed as a morning star at the end of the month, being in elongation on Sept. 3. Venus is conspicuous as a morning star, being at its greatest brilliance on Aug. 5. Jupiter and Neptune are both near the sun; the former is in conjunction on Aug. 26; it will be about 5° from the eclipsed sun on Aug. 31. Neptune will be less than a degree from the eclipsed sun, and may be recorded on some of the coronal plates. A small partial eclipse at sunset will be visible from parts of Galway and Mayo and the islands of Skye and Lewis. Prof. S. Chapman has pointed out that the British Isles are within the region in which effects of the eclipse on wireless transmission may be looked for. Saturn passed opposition on July 24, and is therefore visible for most of the night; but its south declination of 20° makes observation difficult. Uranus is approaching opposition, and may be observed after midnight.

There will be an occultation of the Pleiades on the morning of Aug. 24; disappearances of three stars at the bright limb occur at $1^h\ 20^m$, $1^h\ 41^m$, $1^h\ 50^m$; the times and angles of reappearance of five stars at the dark limb are $2^h\ 6^m$, 198°; $2^h\ 25^m$, 242°; $2^h\ 44^m$, 272°; $3^h\ 1^m$, 227°; $3^h\ 10^m$, 276°. The angles are reckoned from north through east and south.

The Perseid meteors should be looked for about Aug. 10, especially after midnight, as Perseus is then higher; the moon sets at $10^h\ 30^m$ p.m. on Aug. 10.

Newman's comet may be observed with moderate telescopes; the following ephemeris for 0^h is from *Harvard Card* 229:

	R.A.	N. Decl.
Aug. 1	$14^h\ 51^m\ 42^s$	26° 5′
5	14 51 7	27 2
9	14 51 6	27 54
13	14 51 38	28 42
17	14 52 41	29 28
21	14 54 14	30 11
25	14 56 16	30 53
29	14 58 46	31 34

The comet has been observed to throw off nebulous objects; its neighbourhood should therefore be examined.

A minimum of Algol occurs at $0^h\ 5^m$ on Aug. 7.

Add one hour to all times to reduce to Summer Time.

Geology and Archæology of Kharga Oasis, Egypt*

THE second season's exploration of the Prehistoric Research Expedition of the Royal Anthropological Institute to Kharga Oasis, Egypt, under Miss G. Caton-Thompson and Miss E. Gardner, was devoted to the further examination of the 'fossil' or dead springs of Pleistocene age, discovered in the first season, which promised a fruitful line of inquiry in palæolithic stratigraphy and palæo-climatic conditions, and the dating of the tufa deposits and sheets of gravel on the eastern scarp.

On the scarp, the oldest deposit of the 'drift' sequence is a massive crystalline tufa, here named the Plateau Tufa to distinguish it from the later Wadi Tufas. It has no fauna or human evidence and provisionally is placed at Plio-Pleistocene. This was followed by a period of great erosion, causing the formation of transverse and longitudinal valleys, again without cultural evidence. The next stage was the filling in of these valleys in their upper reaches with accumulations of angular breccia, now standing in places as high as 25 metres. This represents a long dry period. On its passing, lower palæolithic man appears on the scene. Rain encouraged vegetation, and the earliest of the Wadi Tufas was formed on the breccia. Unrolled Acheulean tools have been found, thus dating a tufa deposit in Egypt for the first time. The formation of the plateau gravels belongs to this phase. They also have yielded Acheulean tools.

The fifth episode bridges lower and middle palæolithic. An unrolled Acheuleo-Levallois industry has been found in situ sub-tufa. The plateau gravels were eroded and spread in a secondary sheet ("Exogyra gravels"), also containing a mixed Acheulean and Levallois industry.

The middle palæolithic stage is one of considerable but ultimately decreasing rainfall. Another tufa forms over silts and gravels and the formation of the modern drainage system begins. These tufas also are dated by tool floors beneath them. The implements are the products of a tortoise core industry; but it includes so many forms unrecognised in Mousterian industry that it has been named provisionally "Pre-Sebilian". The mode of formation of the tufa is found to be the ponding up of the primary valleys. Pre-Sebilian man frequented the shores of the pools, as is indicated by the collections of tools made from sub-tufa silts.

In the following period the streams grow weaker, and terrace gravels are formed, dual and triple. In an upper terrace were found Pre-Sebilian tools, and on it, in a bed of silt 0·40 m. in thickness, an Aterian flaking site, indicating a lower upper palæolithic date for the Aterian. Here the physiographic sequence ends, and man abandoned the wadis and gravel plateaux surrounding them for the Libyan plateaux where occur the Capsian and Capsian-Tardenoisean sites.

The great flint mines discovered in the first season were re-examined and found to be purely of neolithic age, and not of mixed age as was believed at first.

On the depression floor a magnificent collection of five hundred Acheulean hand-axes was discovered. These were in an area not exceeding 30 sq. metres. and were in mint condition, but glazed. The glaze was certainly produced by sandy waters in a spring and was not due to desert exposure. The hand-axe types are remarkably varied, normally lanceolate forms predominating. With them were their flake industry and cores. In size the axes range from 21 cm. to miniatures less than 4 cm.

A large fossil spring was excavated to a depth of 9 metres. Interstratified gravels, the lowest at a depth of 4 metres, yielded an abundant tortoise core industry which is not Aterian, but its relation to the Levalloisean and Pre-Sebilian on the scarp is not yet clear.

A Capso-Tardenoisean surface site was discovered on the sandrock deposit sealing a fossil spring. The formation of these sandrocks is the final stage in the history of all the fossil springs, and it may, therefore, be inferred that desert conditions obtained prior to the date provided by the surface site.

The cultural elements of the Kharga neolithic were identified. Hearths were discovered in the capping sandrock. Little holes were pierced in the capping sandrock for the supply of water. The curious stone-capped mounds, standing three to four feet high, have been examined and discovered to be the remains of hearths which had originally been holes sunk in the soil and lined with flat pieces of limestone. Since the hearths were abandoned, desert erosion had lowered the ground level. When the stone lining of the hearths was reached, this acted as a protection to the underlying ground and prevented further erosion, so that in course of time the hearth survived as a mound. This indicates a lowering of the desert surface by as much as 6 ft. since neolithic times.

In the matter of general conclusions, it would appear that neither Kharga nor the Fayum is of fluviatile origin, as has been suggested, and earlier views as to the non-existence of a lake in the floor of the depression are confirmed. The deposits formerly attributed to a lacustrine agency are wind-borne loess-like material. There is no dating for this arid period, but it appears to be pre-human.

After neolithic times the Wadi appears to have become uninhabitable and not restored to prosperity until Persian engineers tapped the artesian water bed.

* "The Royal Anthropological Institute's Prehistoric Expedition to Kharga Oasis, Egypt", by Miss G. Caton-Thompson, *Man*, June 1932.

Spectrographic Analysis

BULLETINS recently issued by Messrs. Adam Hilger, Ltd., give particulars of recent advances in methods of spectrographic analysis and in apparatus. The first, No. 168, describes a method of analysis originated by Judd Lewis (*Chemistry and Industry*, **51**, 271-274; 1932) and a range of salts, mixtures called "ratio mixtures", and solutions of high chemical purity under the name of "specpure substances", for use in that scheme of analysis. The method, essentially, is for the determination of elements present in minute proportions, and it applies to all the metals, together with the non-metals silicon, boron, phosphorus, and arsenic. The major constituents having been determined by ordinary chemical analysis, each minor constituent is determined approximately as a ratio of one or other of the major constituents by comparison of the spectrograms of the sample containing the metals in the form of sulphates with spectrograms of the specpure ratio mixtures. Finally, from the data thus obtained, the substance is synthesised by means of the ratio solutions, and a spectrographic comparison is made between the specimen and its synthesised counterpart.

According to the scheme, the specimen and the ratio substances are so prepared that the comparisons are conducted throughout with chemically similar sub-

stances. Lewis has worked chiefly with the electric arc, using electrodes of copper, but it is claimed that the principles involved are applicable to spark and flame spectra, and that the analysis can be made on as little as a milligram of metal, mineral, or ashes of animal or vegetable tissues; further, that good approximate results may be obtained in ordinary practice with no more than average experience.

The ratio mixtures are an extension of the well-known H. S. Brand metals and the R.U. powders detailed in Hilger's booklet No. 94/5. This method, evidently, marks a distinct advance in spectrographic analysis, and it should help to extend the use of the spectrograph in chemical laboratories, in which it is now too rarely employed.

Bulletin No. 169 describes the Müller-Hilger Universal Double Monochromator, which, embodying the principle of double spectroscopic purification, is especially suitable for producing powerful radiations which are strictly monochromatic. The form of construction is original and is the subject of several patents in Great Britain and abroad. Both wave-length setting and focusing are effected simultaneously for the whole instrument by means of a single drum engraved to read in wave-lengths. The optical system is crystallised quartz, and the range of the standard instrument extends from wave-length 0·185 μ in the ultra-violet to 4·0 μ in the infra-red. The relative aperture varies from $F/4$ for 0·185 μ to $F/5{\cdot}8$ for 4·0 μ. The operative beams are axial and the lenses corrected by means of Hilger's interferometers; so that not only are the isolated parts of the spectrum in accurate focus but also every line throughout the spectrum is of good definition.

Messrs. Adam Hilger, Ltd., have just opened new offices and laboratories at 98 King's Road, adjoining their works. The extensions consist of 4400 sq. ft. of office space and 3400 sq. ft. of additional laboratory space, providing ample room for departments which recently have been much congested. The optical glass department will now be housed in the space formerly occupied by the offices. There are at present seventeen principal sections in the works, with eleven chief technicians and four heads of departments.

William John Macquorn Rankine

IN an oration delivered in the University of Glasgow on June 15 at a meeting "in Commemoration of Benefactors", Sir James Henderson paid a tribute to the memory of Macquorn Rankine, who occupied the chair of engineering from 1855 until his death in 1872. Rankine was once described as "the first really powerful thinker in this country to bring the highest mathematical resources to bear on engineering subjects", while the late Prof. Archibald Barr said that he ranked as "the greatest Professor of Applied Science who has yet appeared".

There is a sketch of Rankine's life in the "Dictionary of National Biography", and another by Tait is included in Rankine's "Miscellaneous Scientific Papers", while an obituary notice by Mayer appeared in NATURE of Jan. 16, 1873, but there is still no complete biography of him. In view of this, Sir James Henderson's tribute, printed in full in the *Engineer* for June 24, will be read with interest.

Rankine, who was born on July 5, 1820, died on Dec. 24, 1872, at the early age of fifty-two years, having, however, accomplished an amount of work seldom surpassed by any one. His works on "The Steam Engine" (1859), "Applied Mechanics" (1859), "Civil Engineering" (1862), "Machinery and Millwork" (1869) and other subjects are among the classics of engineering, while to these must be added many scores of scientific memoirs. As a boy of fourteen he read Newton's "Principia" in the original Latin, and at sixteen gained a medal for an essay on "The Undulating Theory of Light"; and in spite of his being trained and his experience as a civil engineer, mathematical physics always made the strongest appeal to him. His work in this direction claimed the chief part of Sir James Henderson's address.

Up to the year 1848, said Sir James, Rankine seems to have been continuously employed as a civil engineer in various schemes, but in that year there occurred a sudden change which it is impossible to explain. The practical civil engineer suddenly becomes the theoretical physicist, and from 1848 until he became professor in 1855, Rankine's energies seem to have been devoted almost entirely to those researches in molecular physics which gained for him the fellowship of the Royal Society in 1853. His early work on this subject was followed by researches in elasticity, hydrodynamics, and thermodynamics. Rankine's contribution to thermodynamics Prof. Tait described as his greatest work. He laid the foundation of the mathematical science as it is known to-day; he applied the second law to heat engines of all kinds, steam engines, air engines, and explosive engines, while in steam engines he introduced the cycle now known as the Rankine-Clausius cycle, which is used as the ideal for engines and refrigerators using vapours as the working substance, and he pointed out that this law is only a particular case of a wider law applicable to all sciences.

At the conclusion of his address, Sir James endeavoured to recall what manner of man Rankine was, and his remarks helped to emphasise the regret that none of Rankine's contemporaries had written his life.

Utilisation of Empire Timbers

AT a recent meeting of the Royal Society of Arts, Maj. J. R. Cosgrove of the Forest Products Research Laboratory read a paper entitled "Empire Timbers, with special reference to their Uses for Furniture and Decoration" (*J. Roy. Soc. Arts*, vol. 80, No. 4136, Feb. 26, 1932). In introducing the lecturer, the chairman, Sir Richard Allison, said that the lecture was opportune, since "in all directions British citizens are faced with the demand to 'Buy British'. With such a commodity as timber apparently much propaganda is necessary to bring home to potential users the possibilities of Empire supplies, and also the beauties of the many woods available for decorative and furniture purposes." He added that for several years past the architects at the Office of Works have concentrated entirely on Empire hardwoods, having satisfied themselves that all their requirements in connexion with buildings can be adequately met by Empire supplies. It is most satisfactory to have such a declaration publicly made, and it would appear to give force to the opinion recently expressed in these columns that the forest services of the Empire require strengthening rather than curtailment, in order to be able to give an answer to the question as to whether supplies of the, at present, mostly unknown timbers could be extracted in sufficient amounts and placed on the markets at an economic price. Without this certainty, it will remain difficult to overcome old-established preferences.

Maj. Cosgrove correctly said that the past few years seem to have caused a profound change of outlook in the people of the British Empire, and with the appeal

increasingly made to support Empire industries he proposed to discuss certain of the timbers obtainable within the Empire, either from home or overseas, which in some form or other may be used for decorative purposes and in the making of furniture. An approximate calculation showed that the value of timber, excluding pulpwood, entering the British market, amounts annually to £40,000,000–£45,000,000, of which about 30 per cent represents hardwoods, much of which goes into utility and decorative work. Of the totals, therefore, of £30,000,000 for softwoods and £12,000,000 for hardwoods, the Empire's share at present works out to somewhat less than 10 per cent for softwoods and less than 30 per cent of the hardwoods; of which latter, however, a large amount, in value at least, is for teak from Burma. The wide use and popularity of foreign timbers is attributed by Maj. Cosgrove to a number of causes—such as the volume in which supplies have been available, their suitability and relative cheapness, the preparation which has been bestowed upon them in the form of careful manufacture, grading, and conditioning, and so forth. This implies that the timbers in use have an assured position, and that users will as a rule purchase them from descriptions alone and usually without preliminary inspection.

After discussing briefly the value of research work, Maj. Cosgrove enumerated some of the hardwoods, from both the British Empire and foreign sources, which are well known on the markets. He then discussed the possibilities of timbers which are particularly suitable for decoration and furniture from Great Britain, India, British North Borneo, Australia, New Zealand, British West Africa, British Guiana, West Indies, British Honduras, and Canada.

Advances in Stereo-Chemistry

THE sixth Messel Memorial Lecture was delivered before members of the Society of Chemical Industry at Nottingham on July 14 by Sir William Pope. Reviewing "Forty Years of Stereo-Chemistry", Sir William Pope traced the important developments of the present century in this branch of organic chemistry, which about 1890 was comparatively dormant, and had largely remained so since the work of Pasteur, van 't Hoff, and Le Bel. Development recommenced with the introduction of an improved technique for the resolution of synthetic mixtures or racemic compounds which followed from the discovery of the sulphonic acids of camphor and their halogen derivatives. The further demonstration that optical activity may be associated with the presence in the molecule of asymmetric atoms of other elements such as sulphur, tin, silicon, phosphorus, as well as the verification among ethylene derivatives of van 't Hoff's prediction of the optical activity of allene derivatives of the type *abC*:*C*:*Ccd*, led chemists generally to realise that the chemical molecule is spread out in three-dimensional space, and prompted subsequent attempts to ascertain the way in which the properties of compounds are influenced by the shape of the molecules.

Sir William Pope referred to the way in which the conception of the asymmetric carbon atom has tended to divert attention from the conditions of mirror-image isomerism defined by Pasteur. The asymmetric carbon atom covers only one, though the commonest, class of mirror-image isomerism. The fundamental condition is that the molecular configuration may possess any elements of geometrical symmetry except a centre of symmetry or a plane of direct symmetry. Thus the molecular configuration of an optically active compound need not be asymmetric or entirely devoid of geometrical symmetry. In the Hantzsch and Werner theory of the configuration of the eximes, illustrated by Mills, or the optical activity and mirror-image isomerism among diphenyl derivatives, discovered by Kenner, are other examples of the way in which the whole of organic chemistry has acquired a stereo-chemical aspect.

While our knowledge of certain branches of stereochemistry is rapidly advancing, the space configuration of the benzene ring and of aromatic compounds in general remains an unsolved problem. Similarly, our knowledge of the combination to a homogeneous crystalline compound of substances with mirror-image configurations is developing but slowly, and little attention has been given to the question of racemic combination between dextro- and laevo-isomerides in the liquid state. Although as yet the novel and powerful methods of modern physics for determining the arrangement of the atoms or even of the components of atoms in solid, liquid, or even gaseous substances, such as X-ray diffraction determinations, the measurement of dipole moments, or the quantitative study of the behaviour of films only a few molecules in thickness, have merely enabled us to confirm the structures assigned on chemical grounds, Sir William Pope suggested that we may be on the verge of fresh developments which will convert the new physical methods into much more searching weapons for the determination of molecular configuration than any formerly at our disposal.

University and Educational Intelligence

CAMBRIDGE.—Applications for the Benn W. Levy research studentship in biochemistry should be addressed to Sir Frederick Gowland Hopkins at the School of Biochemistry before Aug. 1.

A pension of £540 a year has been granted to Sir Joseph Larmor on his retirement from the Lucasian professorship of mathematics, and to Mr. H. A. Roberts on his retirement from the secretaryship of the Appointments Board.

At Clare College, Mr. E. T. C. Spooner, University demonstrator in pathology, has been elected to an official fellowship.

At King's College, E. S. Shire has been elected to an R. J. Smith studentship, and A. G. D. Watson and D. Purdie to Harold Fry studentships.

Dr. P. A. M. Dirac has been elected Lucasian professor of mathematics in succession to Sir Joseph Larmor, who retires on Sept. 30.

EDINBURGH.—At a meeting of the University Court on July 18, Mr. W. L. Edge, fellow of Trinity College, Cambridge, was appointed lecturer in the Department of Mathematics, in succession to Dr. E. L. Ince, who has resigned.

The Cameron prize in practical therapeutics has been awarded to Prof. Edward Mellanby, professor of pharmacology, University of Sheffield, in recognition of his discoveries regarding the therapeutic actions of the fat-soluble vitamins.

LONDON.—The following appointments to University readerships have been made, to take effect from Oct. 1: experimental pathology (Lister Institute of Preventive Medicine), Dr. E. W. Hurst, formerly pathologist to the Millbank Research Fund at the Lister Institute; mathematics (Imperial College—Royal College of Science), Dr. W. H. McCrea, lecturer in mathematics in the University of Edinburgh; pathological chemistry (the Cancer Hospital), Dr. J. W. Cook, research chemist in the Research Institute of the Cancer Hospital. The title of University reader was conferred on the following in respect of posts held at the colleges indicated: geography, Dr. Hilda Rodwell Ormsby (London School of Economics); civil engineering,

Mr. John Purser (Imperial College—City and Guilds College) and Mr. M. K. Rice-Oxley (Imperial College—City and Guilds College); mechanical engineering, Dr. J. V. Howard (Imperial College—City and Guilds College) and Dr. S. Livingston Smith (Imperial College—City and Guilds College).

WALES.—At a meeting of the University Court on July 20, reference was made by the pro-chancellor to the very grave financial position of the University, which has arisen owing to the decrease in the contributions of local authorities since the passing of the Derating Act. Unless there is a favourable outcome to the negotiations which are now proceeding, the University will suffer a reduction in income of about £10,000 a year.

The Council of the Welsh National School of Medicine has appointed Sir Ewen J. Maclean to be an emeritus professor.

IN connexion with the Geneva Institute of International Relations, a conference on Training for World Citizenship will be held at the Institute on Aug. 19–23. Particulars can be obtained from the Secretary, Education Committee, League of Nations Union, 15 Grosvenor Crescent, London, S.W.1.

THE sixth International Conference of University Women is being held at Edinburgh. The Conference was opened on July 27 and will continue until Aug. 4. Included among the lectures being given in connexion with the Conference is one by Dr. Johanna Westerdyk on "Epidemics of Plant Diseases", and another by Mme. M. L. Puech on "Intellectual Co-operation". For the first time, the group discussion method will be introduced, the subject being "Does the University offer to the Modern Woman the Training needed to fit her for Life?": the discussion will be opened by Dr. Aurelia H. Reinhardt.

EDUCATION for commerce was discussed at a meeting of the Royal Society of Arts under the presidency of Sir Francis Goodenough on April 27. A full account of the lecture by Mr. H. Ramsbotham, Parliamentary Secretary to the Board of Education, which preceded the discussion, and of the remarks by a number of authorities, eminent in business and education, who took part in it, has now been published (*J. Roy. Soc. Arts*, June 17). Mr. Ramsbotham emphasised the imperative necessity of co-operation between employers and teachers in connexion with the framing of curricula, recruitment for employment in commerce, and part-time further education of employees. Now that so large a proportion of the younger generation, who would in former times have gone into the factory or the office at the age of fourteen years, remain in school for another two years, it is of vital importance that the needs of the factory and office should not be ignored by the schools. In the course of the discussion, many practical problems were dealt with and elucidated by reference to particular instances. Mr. Chorlton referred to effective training methods in use on the continent, especially Czechoslovakia, where the number of part-time day students of 16-20 years of age is thirtyfold greater in proportion to population than in Great Britain. Mr. Harold Sanderson described a successful experiment in the Burslem (Potteries) district in secondary education with an artistic bias. Miss Ford, H.M. Staff Inspector of Schools, suggested that American experience in child guidance and vocational guidance showed that we do not in Great Britain devote enough attention to detailed systematic examination of children to find out what their aptitudes are. Other speakers dwelt on the necessity for a better understanding on the part of university authorities of the qualifications appropriate for employment in commerce.

Calendar of Geographical Exploration

July 31, 1908.—Interior of New Guinea

D. Mackay and W. S. Little landed in New Guinea and explored the Upper Purari River. They suggested that coal existed in the interior of the island, and as a result Staniforth Smith in 1910–11 opened up for the first time a large area north-west of the Gulf of Papua and east of the basin of the Fly River.

Aug. 1, 1862.—The Kara Sea

P. von Krusenstern, jr., started from the Pechora River on his second attempt to reach the Kara Sea. His boat became fixed in the ice near Yugor Shar and drifted across to the east coast of the Kara Sea, his narrative forming the first complete sketch of a journey from west to east of that sea. He and his men had a series of hairbreadth escapes: their vessel was nipped in an icefield and eventually had to be abandoned. They made their way across the ice, sometimes leaping on to pieces of drift ice which had to be towed by boathooks, but ultimately reaching land and travelling in reindeer sledges to Obdorsk. A curious incident was the attempt of six walruses to accompany them on to a piece of drift ice.

Aug. 2, 1904.—Tibet and the Mustagh Pass

Sir Francis Younghusband reached Lhasa on a political embassy. On the return journey, the Brahmaputra from Shigatse to its source, the Sutlej from its source to the borders of India, and the Gartok branch of the Indus were surveyed by members of the party—a most important contribution to the geography of south and south-west Tibet. In 1886, Younghusband and H. E. M. James set out from Manchuria for India, during which journey they discovered and crossed the Mustagh Pass in 1887. Younghusband's work markedly extended the amount of accurately surveyed area in these regions; he also proved that the Mustagh is the true water parting west of the Tibetan plateau.

Aug. 3, 1868.—Scientific Exploration of China

Baron F. von Richthofen sailed from San Francisco for China, where he carried out his classic survey of that country. In 1859 he had accompanied a Prussian diplomatic mission as geologist, visited Ceylon, Japan, Formosa, the Philippines, and Java, and made an overland expedition from Bangkok to Moulmein. Unfortunately, his records and collections on this journey were lost. In 1877–85 he published three volumes and an atlas dealing with the geology and geography of China, including a notable study of the loess regions. He directed attention to the coalfields of Shantung, to the importance of Kiaochow as a port, and to many other possibilities of economic development. Between 1868 and 1872 he made seven expeditions into the interior of China, visiting, among other regions, Shantung and South Manchuria, central China, Chih-li, and Szechwan.

Aug. 4, 1482.—Mouth of the Congo

Circumstantial evidence points to this as the probable date on which Diego Cam or Cão discovered the mouth of the Congo River. Cam was the first explorer to carry stone pillars to mark newly discovered points, instead of relying on wooden crosses or carved trees. He put up four pillars altogether, two on his first and two on his second voyage. Fragments of the pillar he set up on Shark point to commemorate his discovery of the Congo River still

remain. Cam thence sailed south along the Angola coast and erected a second pillar at Cape Santa Maria in 13° 26′ S. On his second voyage (1485–86) he reached Cape Cross in 21° 50′ S. Thus he discovered 1450 miles of the West African coast-line, and paved the way for the voyages of Diaz and da Gama. An inscription on Behaim's Globe of 1492 suggests that he accompanied Cam on his second voyage, but doubt has been cast upon this statement.

Aug. 4, 1819.—Arctic Exploration by Ship and Sledge

W. E. Parry with the ships *Hecla* and *Griper* reached Lancaster Sound, whence he proceeded westwards, discovering Barrow Strait and parts of the coasts of Bathurst and Melville Islands. The winter was spent on the latter island. In 1821, Parry, on a second voyage, discovered the Fury and Hecla Strait between Baffin Island and Melville Peninsula. On April 3, 1827, Parry set out in the *Hecla*, proposing to attempt to reach the pole by travelling over the ice in sledge boats. He reached 82° 45′ N., thus establishing a record which remained unbroken for nearly fifty years. Experience had shown that efforts to sail to the pole were fruitless; to him and to Sir John Franklin belongs the credit of the introduction of the method of polar investigation by sledge journeys.

Aug. 6, 1538.—Exploration of Colombia

Gonzalo J. de Quesada founded the city of Santa Fé de Bogotá. He reached this region, which he called New Granada, after a difficult journey through uninhabited country along the Magdalena River, which he finally abandoned for the valley of the Opon.

Aug. 6, 1584.—Early Journeys in Siberia

Yermak, the Cossack who opened the path for Russia's expansion in northern Asia, was drowned in the Irtish River. Provided with funds by the Stroganov family, merchants of Perm interested in furs, he penetrated, between 1579 and 1584, to the confluence of the Ob and the Irtish. He reached the Tura in 1580 and wintered on the site where Tiumen now stands: in 1581 he captured the native fortress of Isker or Sibir, near the present Tobolsk. The Cossacks made their journeys in sailing boats, which were dragged across portages from one stream to another. Yermak is said to have used sails to dam up a stream and thus provide sufficiently deep water for his boats. Cossack bands, after Yermak's death, continued to explore north-eastern Asia. No tributaries with easy portages connect the Lena to western rivers, and the Russians who sailed the Lena to its mouth and attempted to explore the arctic in their primitive boats suffered severe hardships, whole parties being often completely wiped out. The importance for geographical knowledge of their journeys was long overshadowed by greed for tribute, and thus the records of their routes were forgotten.

Aug. 6, 1855.—Greenland and the Canadian Arctic

Dr. Kane and his party safely reached Upernavik in small boats, having been compelled to abandon the *Advance*, in which they had set out in 1853. Kane's work included the survey of the east coast of Smith Sound, the discovery and naming of the Humboldt Glacier, the survey of 800 miles of the coast of Greenland, and the discovery and survey of part of the coast of Washington Land. His vessel, the *Advance*, reached 78° 37′ N., and sledge parties penetrated to Cape Fraser in Ellesmere Island and to Cape Constitution in Greenland. A relief expedition under Hartstene found the party at Upernavik.

Societies and Academies

London

Optical Society, June 9.—**R. A. Houstoun**: A new trichromatic colorimeter. The instrument is on a new principle, the intensity of the comparison field being altered by an iris diaphragm, and the colour by moving a magenta-yellow and a blue-magenta filter relatively to one another.—**T. Y. Baker**: The parallel plate micrometer. A plate of parallel glass placed in the convergent beam of a reading microscope is a useful means of obtaining the 'fine-reading' of a divided circle. The fine-reading scale is uniform if its length is proportional to the tangent of the angle through which the plate is tilted and if the refractive index of the glass is 1·60.—**J. Adamson**: A study of the cyclo-rotational powers of the eyes. An expression for the 'false torsion' of the eye is derived in terms of the direction of its line of fixation, and is used in calculating the extent of the compensatory cyclo-rotational powers of the eyes.—**T. Smith**: The hiding power of diffusing media. From theoretical considerations an expression is constructed as a numerical measure of the power of a sheet of a diffusing medium to hide the brightness contrasts of a surface on which it is laid. The dependence of this factor on the transmission and reflection factors of the sheet is exhibited and the effect of varying the thickness of the sheet is discussed. A comparison is made of these theoretical results with published experimental observations. The properties of all sheets may be expressed in terms of two constants, of which one is the reflection factor for an infinitely thick sheet, and the other is a factor for converting sheet thicknesses to the proper numerical scale.

Geological Society, June 22.—**Jane Longstaff** (née **Donald**): A revision of the British Carboniferous members of the family Loxonematidæ, with descriptions of new forms. Many Carboniferous species have been referred to the genus *Loxonema* (Phillips) which do not strictly belong to it. This is the case with Etheridge's Catalogue, where 25 species are given. Some of them, however, belong to the family Loxonematidæ as defined by Koken, and are referable to several of the genera into which it has since been divided. These are *Zygopleura* Koken, *Katosira* Koken, *Microptychis* Longstaff, and *Hemizyga* Girty. Three new genera are suggested for other species. The genus *Zygopleura* Koken contains by far the largest number of the species; one of these, *Z. rugifera* (Phillips), exhibits a considerable amount of variation both in size and ornamentation. The nuclear whorls, also, accord more with that genus than with *Pseudozygopleura* Knight. Twenty-six species and several varieties are described, 13 of the former being new. Six had been previously noted by de Koninck as common to Belgium, and another is now recorded: namely, *L. subconstricta* de Koninck.—**Archibald Allison**: The Dalradian succession in Islay and Jura. The author outlines results recently obtained by himself through the application of the criteria of current bedding and graded bedding, restricting his attention to the Dalradian rocks north and east of the Loch Skerrols thrust. Previously, this method of study has scarcely been used in Islay. The evidence of original order of succession is abundant, widely dispersed and consistent. Combined with the fact that the Maol an Fhithich Quartzite appears naturally to underlie the Mull of Oa Phyllites, it leads the author to conclude that the structure of Islay is an anticline, in part steeply overturned towards the north-west, in complete agreement with the views of Prof. E. B. Bailey as expounded in his paper on the Islay anticline.

DUBLIN

Royal Dublin Society, April 26.—**T. A. Bennet-Clark**: (1) A method of automatically recording the rates of oxygen intake of living tissues. The tissues are enclosed in a container forming part of a closed system through which the air is circulated by means of a special form of pump. The carbon dioxide evolved by the tissue is absorbed in baryta water in a series of Pettenkoffer tubes, as in Blackman's apparatus. The oxygen absorbed is replaced automatically by oxygen generated electrolytically whenever the fall in pressure in the apparatus, due to absorption, raises the liquid electrolyte in a differential manometer tube so as to make contact with an electrode. This enables the composition of the air surrounding the tissue to be maintained constant for a long period of time without constant attention. The rate of oxygen supply is recorded automatically, and the volume of carbon dioxide is found by titration every two hours. —(2) The respiratory quotients of succulent plants. Some measurements on *Sedum prealtum* leaves, with the apparatus described above, are in harmony with the view that the large variations which occur in the respiratory quotient (the ratio of carbon dioxide evolved to oxygen absorbed) for many hours after the leaves have been placed in darkness may be explained by variations in the quantity of malic acid present in the leaf.—**E. J. Sheehy**: Factors which determine the nutritive value (stock carrying and fattening capacity) of untreated natural pastures. Neither the chemical composition nor the digestibility of the dry matter of a pasture may be used as a criterion of its nutritive value. Fattening capacity depends upon the percentage of dry matter and on the density of the herbage, while stock carrying capacity is affected in addition by its rate of growth. These factors are correlated with the botanical composition.

PARIS

Academy of Sciences, June 13 (vol. 194, pp. 2093-2180).—**H. Deslandres**: Simple relations between the molecular spectrum and the structure of the molecule. —**Gabriel Bertrand** and **L. Silberstein**: The presence of mineral sulphides in an arable soil. A soil which reacted unfavourably towards growing plants was found to contain sulphides, decomposed by hydrochloric acid but not by acetic acid.—**d'Arsonval**: The medical applications of radioactive emanations, from the works of G. Vaugeois. A description of a method due to the late G. Vaugeois of utilising the emanation, for which certain advantages are claimed.—**Léon Guillet, Auguste Le Thomas**, and **Marcel Ballay**: The properties of copper-nickel alloys containing tin and silicon used for steam valves. The working properties of copper-nickel alloys are improved by the addition of tin and silicon. Detailed results with 37 alloys are given.—**C. Camichel** and **L. Escande**: Similitude of under-load without real linear dimensions. A discussion of Reynolds's equation of flow of incompressible viscous fluids in systems, such as submarine currents, which have no real linear dimensions.—**Maurice Janet**: The explicit determination of certain minima in problems without conditions at the limits. —**P. L. Srivastava** and **S. P. Jain**: The singularities of the Laplace-Abel integral.—**C. E. Winn**: The relation between a given series and another derived series with the same interval of oscillation.—**N. Cioranesco**: New problems on partial differential equations of the second order and of hyperbolic type.—**W. Orlicz**: Some theorems on orthogonal series.—**Mlle. M. L. Cartwright**: Some properties of the directions of Borel of integral functions of finite order.—**Pierre Ernest Mercier**: The intrinsic forms of the laws of plane motion (permanent motion).—**Émile Sevin**: Concerning the rôle of the rotation of material particles in the evolution of the universe.—**Lew Kowarski**: Very thin crystals with curved outlines. From a study of the crystals formed by the sublimation of some organic substances, especially *p*-toluidine, it is concluded that an entirely polyhedral form is not a necessary attribute of the crystalline state; it is only the final term of an evolution. Certain substances can show curved surfaces.—**D. G. Dervichian**: Surfaces and molecular volumes in superficial solutions.—**R. Lucas** and **P. Biquard**: New optical properties of liquids submitted to ultra-sound waves. Photographs of interference effects produced by passing a beam of light through water submitted to ultra-sound waves (3-15 million periods a second).—**Jean Cabannes**: Laws of polarisation of Raman lines in crystals.—**Constantin Salceanu**: The influence of temperature on the natural and magnetic rotatory dispersion of three pinenes.—**Réne Wurmser** and **Mlle. J. De Boe**: The oxido-reduction potential of the system lactic acid, pyruvic acid.—**W. S. Reich**: Contribution to the study of glycogen. By an elaborate process of purification, the author has produced glycogen containing less than 0·002 per cent phosphoric anhydride. The purified substance retains all the essential properties of glycogen; and hence it is concluded that phosphoric anhydride is not an essential constituent of glycogen.—**Hardouin, Cochet**, and **de Fleury**: Viscosities of flux and slag in the fusion of magnesium.—**Urion**: The thermal decomposition of the acyloins.—**Maurice Leriche**: The traces of an estuary formation, of Ypresian age, changed at the base of the Lutetian at the western edge of the Paris basin.—**H. Vincienne**: The horizontal disengagements in the south of the Jura: the tectonic and morphological rôle.—**Edouard Roch**: Geological observations in the region of Entifa and Beni Ayatt, to the north-east of Marrakesh (Morocco).—**V. Frolow**: The dissolved salts in the underground waters of the Palmyre region. The variations in the dissolved salts in three springs in this region with the time of year have been determined, and the results given graphically.—**A.** and **R. Sartory, J. Meyer**, and **M. Antonioli**: Cytological researches on the development of *Actinomyces Allenbachii*.—**Paul Becquerel**: The revivification of dried seedlings after placing in a vacuum and at very low temperatures. Seedlings of wheat, rye, lucerne, and annual sunflower, after prolonged drying in a vacuum, with subsequent exposure for 18 days at − 190° C. (liquid nitrogen), and to a further treatment at − 269° for 9 hours and − 271° for one hour (liquid helium), with two exceptions, developed normally. —**R. Echevin**: The autumnal migration of phosphorus in the leaves of trees. During the change in colour from green to yellow, the protein phosphorus diminishes.—**Mme. H. Heldt**: Fertilisation in *Parapenæus longirostris*.—**Paul Wintrebert**: The primitive streak of amphibians; a new phase of the development shown by the coloured markings.—**Marcel Avel**: An experiment permitting the regeneration of the head in the proved absence of the ventral nerve chain in *Lumbricus*.—**E. Biancani, H. Biancani**, and **A. Dognon**: The action of ultra-sound waves on isolated cells in suspension.—**Georges Deflandre**: The genus *Podamphora* and its relations with the Ebriaceæ.—**F. Labrousse**: The fluorescigen function in the phytopathogenic bacteria. In two bacteria studied, the fluorescence depended on the amount of magnesium phosphate in the culture fluid.—**A. W. Sellards** and **J. Laignet**: The control, by a test on *Macacus rhesus*, of the protective power of the serum of men vaccinated against yellow fever with mouse virus. The tests prove the high degree of immunity conferred by this method of vaccination.—**E. Roubaud** and **J. Colas-Belcour**: The adaptation to submerged life during the winter in the larvæ of *Anopheles plumbeus*.

CRACOW

Polish Academy of Science and Letters, March 17.—**A. Skapski**: *Endosmosis through a semipermeable spherical membrane.*—**Mlle. A. Dorabialska**: Researches on the anomalous thermal effects given by some radioactive minerals. It has been proved that these anomalous effects cannot have been caused by secondary physical actions, such as adsorption of vapours or gases. From the study of two minerals, orangite and monazite, the thermal effect has been found to reside in the fractions containing the elements of the lanthanum and yttrium group. Cerium and erbium do not give out thermal energy.—**M. Centnerszwer** and **S. Lewi**: The influence of the temperature on the velocity of solution of thallium in nitric acid. The temperature coefficient $K_{35°}/K_{25°} = 2{\cdot}06$; agreeing with the data of van 't Hoff for the effect of temperature on chemical reactions.—**M. Centnerszwer, Mlle. C. Weker,** and **Mlle. S. Majewska**: The velocity of evaporation of liquids in a current of air. Experiments on the velocity of evaporation of water, benzene, and toluene and its variation as a function of the velocity of the current of air.—**K. Dziewoński** and **J. Moszew**: *A new method of synthesis of compounds derived from quinoline.*—**Mlle. M. Turnau**: Some remarks on the geometric analysis of rocks.—**H. Teisseyre**: The morphological problems of the eastern Polish Sub-Carpathians.—**W. Friedberg**: The Miocene Pectinideæ of Poland and their stratigraphical value (1).—**F. Rogoziński** and **Mlle. J. Ciechanowska**: Experimental rickets (4). Wheat as a food causing rickets. The rickets produced in white rats and chicks by an exclusive wheat diet can be prevented by adding calcium salts in sufficient quantity to ensure a proper ratio of calcium to phosphorus.

ROME

Royal National Academy of the Lincei, Feb. 7.—**U. Cisotti**: Motion with 'wake' of a flexible profile (1).—**L. Lombardi**: An absolute voltmeter for the measurement of large differences of potential. On May 1, 1931, Prof. W. M. Thornton described an absolute voltmeter composed of a metallic ellipsoid of revolution, suspended between two plane parallel armatures, with its major axis inclined at 45° to the direction of the field. This device was applied and exhaustively discussed by the author in his doctorate thesis at Zurich in 1895.—**G. Giorgi**: New ideas on the theory of relativity. The theory of relativity has passed through three stages, the first termed restricted relativity, the second improperly named generalised relativity, and the third including the scheme of Einstein for a unitary description of gravitational and electromagnetic fields and those of other authors having the same purpose. Suggestions are now put forward which may lead to a further advance.—**E. Paternò**: (1) Cellulose xanthate and viscose.—(2) Soluble or peptonised cellulose. The form in which cellulose exists in its colloidal solutions is discussed.—(3) Composition of artificial silk. The experimental results described indicate that viscose silk is not hydrocellulose, but a mixture of a form of cellulose not yet defined with a substance which may be dissolved from the silk by soda solution.—**T. Boggio**: Certain vectorial formulæ in curved, three-dimensional spaces. The way in which some of the more common formulæ of ordinary space are modified in curved spaces is considered.—**G. Sansone**: Zeros of the polynomial solutions of the equation $(a_1x + a_0)y'' + (b_1x + b_0)y' - nb_1y = 0$ (ii).—**C. Miranda**: The summation of Hermite's series by Poisson's method.—**L. Campedelli**: Double planes with curve of branching of the eighth order.—**N. Sakellariou**: The calculus of variations.—**Giacinta Andruetto**: Saint-Venant's formulæ for curved spaces of three dimensions.—**G. Krall**: Asymptotic effects of the tides on the motion of the celestial bodies. (1) Generalities and problem of two bodies.—**R. Serini**: The Doppler phenomenon for vibrating cords.—**V. Zagami** and **V. Famiani**: Comparison between the food value of certain vegetables and that of certain cereals. Experiments with young albino rats show that increase in weight and development of the genital organs are retarded by exclusive feeding of the animals on peas or lentils, and that still greater effects are produced if cereals form the only food. Less pronounced calcification of the skeleton and other bodily defects are also observed.—**Giulio Cotronei**: Zoological constitution and grafting (9).—**M. Curzi**: Contribution to the knowledge of the biology and systematics of strains of *Sclerotium* Rolfsii.

Industrial and Business Administration

BEHIND the growing attention which is focused in these days on planning as an integral element in industrial revival or in national and international recovery, there is an increasing consciousness that the demands which are habitually made on leadership, whether of industry or of the State, are far more onerous than those of a few decades ago. It is not sufficient now for an industrial administrator to be competent to assess merely the internal and local factors of his industry. Whether they are financial, economic, political, or technical, he is compelled to extend his view to the national industry as a whole, and beyond that to an increasing extent to the industry as a world unit. Indifference to the international aspects of industry, like neglect of the technical and scientific factors, invites disaster, and this is as true of national administration as it is of industry. It would be difficult to name a single first-class problem with which modern political administrators are confronted which does not involve in its solution intricate and essential technical and scientific factors which cannot be appraised apart from scientific and technical knowledge.

As we have repeatedly urged in these columns, both industry and the State have in Great Britain suffered too much in the past from administrators whose deficiencies in scientific outlook and knowledge rendered them incapable of maintaining an adequate scientific staff, or of accepting an adequate and sustained programme of research as a fixed charge, comparable with insurance, depreciation, or obsolescence, and incorporating its results in industrial practice. In industry, however, this tendency is passing. The successful development of the newer industries such as those concerned with electrical equipment, automobiles and aviation, or the manufacture of synthetic products such as rayon, resins, etc., which has been primarily dependent upon research and the application of the results of scientific and technical investigation in commercial practice, has involved the organisation of close co-operation between administrators and controllers of policy and those responsible for research and other technical matters. The increasing authority and prestige of the technical expert in such industries is now extending to older industries, as may be seen in the appointment of an eminent man of science to direct and co-ordinate all research for the London Midland and Scottish Railway, an appointment carrying a status corresponding to that of the principal directing heads on the administrative side.

As a result of these developments in industry, there has thus been a considerable change from the control of industry by those whose chief qualifications are financial and commercial to control by boards of directors which collectively combine the knowledge of finance, general organisation, administrative problems, and the trend of scientific and technical developments requisite for wise and far-seeing decisions on general policy. To this process the merging of industrial undertakings for the purposes of technical rationalisation has given a further impetus. Much of the wider and more urgent interest in management problems is derived from the rationalisation of industry. In fact, it may be said that the brief history of rationalisation in the world has already convincingly demonstrated that the success of a rationalisation policy is bound up inseparably with leadership competent to evaluate accurately all the relevant factors involved, whether scientific, technical, financial, or commercial. It is probably deficiencies in one or other of these respects, and consequent failure, that has led to suggestions that efficient administration of some of the largest international mergers is a task beyond human powers. Authoritative inquiry has, however, failed to reveal any evidence of such inherent limitations on human ability, and public opinion is gradually becoming sufficiently enlightened to perceive the true cause of such failures as lying in those who insist on discussing questions and policies involving technical or scientific considerations without the assistance of the appropriate experts.

Evidence of this change in the attitude of industry, and indeed of public opinion, can be found in the progress of such diverse institutions as the International Management Institute with its associated Management Research Groups, the Institute of Industrial Administration, which aims at establishing industrial administration as a recognised profession, as well as in the inclusion of a discussion on scientific management problems in the programme of Section F (Economics) at the centenary meeting of the British Association last year.

Among these, one of the most interesting experiments is the Department of Business Administration at the London School of Economics and Political Science.* Established in 1930 through the joint efforts of leading business firms and school authorities, and financed mainly by business subscribers, the Department of Business Administration provides selected students with full-time training in the broad principles of business administration, as well as, where necessary, giving a preliminary general economic training. The Department does not aim at large numbers of students but at giving personal attention to a limited number each of whom has given evidence of an adequate general education and of personal qualities likely to make them suitable for a business career. The primary object of the training is to develop the quality of judgment and the breadth of view required for solving the practical problems which are encountered in business life. A secondary object is to provide a background against which the students can place the problems they afterwards meet.

With these objects in mind, instruction is carried on mainly by means of small discussion classes, including what is known as the problem or case method, supplemented by written work. Material supplied by business firms and illustrating the actual problems of business life is used in class discussions. In addition, the systematic investigation of business problems, organisation, and methods, mainly from the point of view of the individual concern, forms an integral part of the Department's work, and in time the Department hopes to cover a number of the major fields of business activity, although its present plans are limited to the study of certain aspects of marketing and business finance. In the latter field an investigation has been undertaken on the financial structure of business with the object of ascertaining whether normal forms of capitalisation exist for different types of business.

The Department of Business Administration is thus a definite attempt to meet the need for business training which is at present so ill provided for. Obvious criticisms can be made of its aims and methods, but it is not suggested that the course can do more than assist the formation and development of habits of judgment which will mature in actual experience of business and industrial life. The training provided by the Department has new advantages in the extent to which it renders available for the coming generation of administrators the experience of many firms of varying sizes and in different branches of industry or commerce. The breadth of experience thus offered is far greater than could be acquired in any one firm, apart from the practical difficulty which would be encountered in a firm of any size in the student acquiring experience by working his way through the different departments of the firm.

The scheme of training thus briefly outlined is an

* The London School of Economics and Political Science (University of London), Houghton Street, Aldwych, W.C.2. Department of Business Administration, Session 1932–33. Pp. 28. Training for Business Management. Pp. 11. (London, 1932.)

experiment which is still developing and has not reached its final form. It can be justly claimed for this novel attempt to meet the need for fresh methods of recruiting and training business administrators for the future which arises from the changed economic conditions of the world, that it is based on a closer co-operation of academic and business authorities than has hitherto been achieved in Great Britain, and without abandoning any academic standard it seeks to base training for business upon business. It should not be too much to hope or expect that training along such lines will assist in the development not of scientific management as a restricted profession, however efficient, but in the provision for industry and the State alike of administrators versed in tried principles of administration and competent to assess the technical and scientific factors entering into problems they are called upon to solve. A generation of such administrators in government service and in industry would speedily ensure that the scientific expert took his rightful place in the business or mechanism of government in industry or in the State.

Inevitably, administrators of the required standard will only be forthcoming if the recruits for such courses are drawn as freely from scientific workers as from those who have graduated in arts or law or economics, and if the government service is at present lamentably behind industry in the scope it affords for administration by those having first-hand knowledge of science, the present tendency towards functional representation will ultimately make it easier for industry to influence State administration in the same direction. The firm establishment of the expert and the expert committee in industrial administration, and the proof of the scientific worker's competence to meet the searching demands of administration in an industrial merger on an international scale, should finally result in the scientific expert taking a corresponding part in the machinery of national and international government. Already the value of the expert committee has been demonstrated in the international sphere, and it behoves the scientific worker to watch with great interest all such experiments as that of the Department of Business Administration which seek to raise the standard of industrial administration or to promote scientific management, and to lose no opportunity of qualifying himself to discharge more efficiently those administrative functions from which in the present age he cannot escape, if industry and society alike are to avoid disintegration.

Matter and Conceptions

The New Conceptions of Matter. By Prof. C. G. Darwin. Pp. viii + 192 + 6 plates. (London: G. Bell and Sons, Ltd., 1931.) 10*s.* 6*d.* net.

IN this book the author aspires to a popular account of the recent developments of atomic physics—in particular, that aspect of it which is known as 'wave-mechanics'.

"I believe [he writes of his presentation] that it makes a consistent formulation of the foundations, which only needs the help of mathematics to yield all the results of the theory so far obtained. However that may be, I have little hesitation in saying that, if it is to be at all possible to present the new mechanics in popular or even semi-popular terms, it must be done more or less on the lines I have adopted here."

Speaking broadly, the method referred to may be described as that of giving a familiar physical interpretation to the mathematics of the subject. Since the mathematics does not on the whole lend itself to very obvious interpretation, this leaves considerable scope for the ingenuity of the expositor, and Prof. Darwin's chief difficulty has been to interpret the equations in the most 'natural' way.

"I shall count myself as having succeeded [he writes], if at the end of the book any surviving reader will speak no longer of the mysteries of science, but, shall we say, of the naturalness of Nature."

It may be said at once that, if we admit the legitimacy of the aim, the task could scarcely have been performed more satisfactorily, and many a student of advanced physics will call Prof. Darwin blessed. Every such student should read the book, for it provides him with what he will not obtain elsewhere with the same completeness and general excellence; namely, an approach to the incomprehensible mathematics of the subject by way of the physical counterparts of equations in more familiar branches of physics.

The account of the diffraction of electrons, the real starting-point of the book, is prefaced by some seventy pages of introductory matter dealing with fundamental physical conceptions, wave motion, and the principle of least action. As an interpretation of the new experimental facts we are introduced at once to the uncertainty principle and the duality of wave and particle, and in the light of these basic conceptions the structure and behaviour of the atom, polarisation of waves and particles, collisions between particles, and the exclusion principle are successively discussed. The

treatment is well conceived, clear, and very interesting, and it is difficult to see how in its general features it could be improved.

If, however, we consider the book not 'as in itself it really is' but in relation to its object, we can only describe it as a magnificent failure. Success, indeed, seems to us impossible, for it presupposes a reading of the lessons of modern physics which we cannot accept. To Prof. Darwin, mathematics (or, as we prefer to say for the sake of generality, logic) is the scaffolding by which physical models are erected, and his task is to remove it and reveal the structure.

> "The new discoveries which I am to describe were only begun five years ago, and so it is hardly surprising that they are still partly covered with the scaffolding of mathematical formalism. But I hope to show that the time has already come, when it is possible to free the structure from a good deal of this scaffolding and so to gain something of an intuitive view of what the world is really like."

What are the facts? Simply that until lately there has always been a one-to-one correspondence between the concepts of atomic physics and objects of experience, but that the latest concepts have no empirical correlatives. Prof. Darwin's view is that such correlatives exist and we have to find them; if he is right, then his aim is capable of fulfilment. But it is a possible interpretation that the whilom correspondence was a merely superficial characteristic, and that its breakdown is not a temporary inconvenience but an indication that in our investigations of the relations between phenomena we have got below the surface. If that is the truth, then Prof. Darwin sits in the chair of Cnut.

It is, of course, a matter of opinion at present, and Prof. Darwin's opinion is entitled to as much weight as another's. We cannot, however, think that his book will lend it much support. If anyone, on reaching the end, speaks of the 'naturalness of Nature', it will be in the hushed tones due to departed majesty. More than once Prof. Darwin finds it necessary to apologise for the imperfection of his descriptions of ideas "which are mathematically fairly easy", whereas, we think, he should have apologised for their success, because in so far as they succeed they are of necessity misleading. A great part of the book is, of course, concerned with the view of the electron as a wave, but if the reader asks, 'A wave in what?', he will find no answer unless he wrongly, but perhaps excusably, interprets pp 22-23 as replying, "Waves in the luminiferous ether". He may succeed in realising that the wave and particle aspects of the fundamental concepts are not contradictory but complementary, but he will not discover why they should both exist or how they can be unified. The only answer provided to the old query why one aspect is presented on Monday, Wednesday, and Friday, and the other on Tuesday, Thursday, and Saturday, is that one day does not overlap another. This falls somewhat short of "an intuitive view of what the world is really like".

It is questionable whether even some of those who admit the unpicturability of modern physical concepts have realised the revolution which it causes in the principles of popular exposition. We speak of 'wave mechanics', and thereby introduce a completely false idea. When an elastic solid ether was the orthodox belief, it was permissible to speak of waves in the ether just as one spoke of waves in water. The two waves were not merely interpretations of the same equations; they were physically identical interpretations. But an electron and a water wave are not physically identical, and it is as misleading to call an electron a wave as to call a water wave an electron. Our language has suddenly become figurative, and it is not realised that in using it for the uninitiated the impression made is as if, for example, we claimed that the unliberated content of Pandora's box was Watts's well-known picture because both are represented by the symbol 'hope'. Men of science have turned poets, and the public takes their metaphors literally.

If, however, we are prepared to swallow this camel, Prof. Darwin provides us with very few gnats to strain at in the way of incidental analogies. This is one of the most pleasing features of his book, and it is therefore extremely unfortunate that one of the few analogies which are introduced should be a particularly bad one and should deal with a particularly important point. The wave and particle aspects of the electron are likened respectively to the objective and subjective aspects of a sound or colour because of their absolute separation but interdependence. The question of analogy in popular description is so vital and so consistently neglected that it might not be out of place to give it a brief general consideration here.

It is easy to prove that an analogy is at best worthless and at worst misleading. The analogue, not being identical with the point to be illustrated, has certain relevant and certain irrelevant elements. If the reader does not already understand the point in question he has no means of distinguishing between them, and if he does understand it the analogue is superfluous.

Actually the human mind gets round this logical obstacle by virtue of the fact that certain previous experiences spontaneously spring to mind when the analogue is mentioned, and these are accepted as the relevant elements. It follows that a successful analogue will be one of which the relevant elements really are those which will thus spontaneously occur to the reader. Thus, the solar system was, on the whole, a successful likeness to the Rutherford atom; it led no one to think of electrons as abodes of life, though, it is true, a student might have conceived of them as rotating bodies before there was justification for that idea. The outstanding fact of the solar system, however, is the revolution of satellites round a central mass, and the analogue was a good one because that was the relevant element of it.

Prof. Darwin's analogy, on the other hand, is a bad one, because the contrast between 'subjective' and 'objective' will be immediately interpreted, by most readers at least, as a contrast between something existing in the 'mind' and something existing in the 'external world'. Just as a deaf person will have no subjective experience of the 'middle C', but may yet know all about its objective aspect through mechanical experiments, so —the reader will imagine—he himself might, by physical injury, lose the power of detecting the particle aspect of an electron, but retain intact his appreciation of the wave aspect. He will then wonder why the particle aspect is introduced into the scientific description at all, and if he has chanced to hear elsewhere that Heisenberg and Bohr, with reference to a different point, have claimed to show that subject and object are inextricably interwoven in physical theory, he will be fairly caught in a net of confusion into which Prof. Darwin's habitual clearness of expression, so far from delivering him, will only draw him the tighter because of his unwillingness to believe it to have failed. It is much to be hoped that in future editions this objectionable illustration will be removed.

Prof. Darwin more than once, and rightly, insists on the principle that 'unobservables' must be expelled from physical discussion. This is undoubtedly the great contribution of modern physics to thought in general. It is of the first importance, therefore, that it should be stated precisely, and this unfortunately is not done. We refer not so much to the statement (p. 81) that "if a thing is essentially unobservable then it is not a real thing", which might lead to misunderstanding among those whose definition of reality is not that of the physicist, as to the discussion on p. 156 which culminates in the remark:

"It is meaningless ever to ask what has happened, unless there is either a direct or an indirect observation to tell one; and if there is an observation it is pointless to ask, because one knows the answer."

The necessary conclusion is that in no circumstances is it anything but futile to ask what has happened. The true point of the principle is that events which cannot *conceivably* be observed, owing to their relation to the processes of observation, are taboo, and that is a very different thing. It allows us, for example, to discuss the far side of the moon, which on Prof. Darwin's principle is illusory.

The book is well produced, and contains several original diagrams. Herbert Dingle.

Fashions in Deformity

Artificial Cranial Deformation: a Contribution to the Study of Ethnic Mutilations. By Dr. E. J. Dingwall. Pp. xvi + 313 + 54 plates. (London: John Bale, Sons and Danielsson, Ltd., 1931.) 70*s*. net.

ONE of the strangest eccentricities in human behaviour is revealed in the widespread practice among even civilised men and women of bodily mutilations, such as scarring and tattooing, piercing ears, noses, lips, or tongue, circumcising, knocking out teeth, compressing the feet, amputating fingers, compressing the waist, and distorting the head. These procedures are so devoid of rational justification and so destructive of the natural beauty of the human form that it is difficult to discover any plausible excuse for their invention. Hence the geographical distribution of such deformities affords valuable evidence in support of claims for the diffusion of culture in early times.

Obviously it is a matter of importance to submit the evidence relating to each of them to the most critical and exhaustive study to discover whether in fact they do throw any decisive light on theories of diffusion or independent development. Dr. Dingwall has performed the onerous task of collecting and setting forth the facts relating to the practice of deliberately deforming the heads of children so as to confer upon them more or less the fantastic and unnatural shapes which fashion dictates for the aristocracy of certain peoples. He has refrained from drawing conclusions: he has attempted to cite the evidence with complete impartiality, without neglecting, however, the important matter of recording the associated customs and beliefs. Although he cites nearly 1200 memoirs

and treatises, he modestly disclaims regarding this list as an adequate bibliography.

Writing in 1915 of the diffusion of culture, I directed attention to the fact that the practice of cranial deformation was intimately associated with the megalithic complex, and tentatively suggested that the distortion of the head may have been first invented in Asia Minor and secondarily associated with the custom of building rude stone monuments in the course of its diffusion. The observations of Dr. L. H. Dudley Buxton, the results of which were given verbally to Dr. Dingwall (and since published, in part, in the *Anthropologischer Anzeiger,* 7, p. 236; 1931), establish the fact that the earliest actual examples of artificially distorted skulls so far recovered come from Crete and Cyprus. They belong to the period of "the late Minoan III., when Bronze Age Cretans had a lively trade with Egypt". From this period in Egypt there have been recovered several busts of Akhenaten's daughters (1360 B.C.) displaying extreme forms of the same intentional cranial deformation; and in the pictures of the Heretic King himself and of his Queen a less extreme form of the same peculiarity is suggested. In spite of the doubts which have been expressed, it is beyond question that Akhenaten's portraits reveal pathological changes, which afford a measure of justification for his artists' fantastic exaggeration of his peculiarities. Whether or not this fashion in mutilation began from an imitation and exaggeration of Akhenaten's natural affliction it will be impossible to decide until authentic skulls of the period have been found. Yet there is positive evidence that about the same time artificial deformation was being practised in Crete and Cyprus.

Dr. Dingwall gives fully documented evidence of its practice in past and present times in Europe, Africa, Asia, the Malay Archipelago, Melanesia, Polynesia, and especially in North and South America, including descriptions of the technical methods employed to effect the mutilation. "We may well ask", he remarks (p. 237), "with Quatrefages whether it is coincidental that the deformed skulls of the Caucasus, France, and America are so similar." "Writing in 1889 he (Quatrefages) says that it is indeed difficult to admit that the idea of deforming the human head in such an extraordinary way has been independently evolved in each of those peoples where we see its manifestations." Quatrefages adds: "one is forced to admit evidence both of diffusion and the contact of cultures". Dr. Dingwall thinks that this opinion "is not to be passed over lightly. The custom of cranial deformation is not uniform in all parts of the world. It cannot be the response to some innate human impulse. Confining the custom almost exclusively to a certain class suggests that the idea is either derived from, or connected with, some notion concerning differences between aristocracy and commoners."

In the laborious task of collecting and setting out the enormous mass of data concerning one of the strangest eccentricities of human fantasy, Dr. Dingwall has rendered a conspicuous service to all students of human history. The book is well illustrated with photographs, drawings, and maps. It should be included in every library concerned with anthropology or the vagaries of human inventiveness. G. Elliot Smith.

British Beetles

A Practical Handbook of British Beetles. By Norman H. Joy. In 2 volumes. Vol. 1. Pp. xxvii + 622. Vol. 2. Pp. 194 (170 plates). (London: H. F. and G. Witherby, 1932.) 63*s.* net.

A DESIDERATUM of long standing was a reasonably priced manual on British Coleoptera. The standard work by Fowler, and especially its illustrated edition, is beyond the means of most students and collectors of insects. In supplying this want, Dr. Joy has set himself the difficult task of dealing in a limited compass with a fauna of about 3560 different species. He approaches his subject with a background of wide experience as a coleopterist, and with a keen appreciation of the difficulties, which especially beginners encounter, in the identification of so many of the species of the order. He has, therefore, written what is essentially a manual of identification for the use of collectors.

The subject matter is arranged in the form of dichotomic keys: first, keys to the superfamilies (or suborders, as the author terms them), then keys to the families of each, and so on down to the genera and species. His principle is to select diagnostic or critical characters, so far as possible, in each series of keys, and so avoid detailed technical descriptions. Ample cross-references to text and plates are given, and much space is saved by the use of abbreviations for frequently recurring terms and for indicating distribution. The essential letterpress fills vol. 1, while vol. 2 consists of 169 plates portraying species and structural details in more than two thousand separate figures. These latter are, for the most part, original, and are reproduced as clear line illustrations. With the aid of these two volumes, the process of identifica-

tion has been reduced to the limits of simplicity, without, it is to be hoped, undue sacrifice in other directions.

In the taxonomic arrangement of the book, convenience takes precedence over orthodox scientific sequence. Thus, the work begins with the Brachelytra and ends with the Clavicornia. The nomenclature followed is mainly that of Heyden, Reitter, and Weise (1906). Here possibly difference of opinion may arise as to how far this system is sufficiently modern for certain of the groups.

Viewed as a whole, it may be said that the author has carried out his task extremely well. His unconventional treatment may annoy purely scientific users, but it has definite advantages. We think that the beginner, more especially, will prefer Dr. Joy's volumes to any others, and for that reason they will impart fresh stimulus to the study of British Coleoptera. The two volumes are excellently produced: the paper and binding are good and the type large and clear; misprints are few. Mention must also be made of the very efficient indexes. The book deserves every success, and if regular usage proves it to be accurate and reliable we think that its success will be assured.

A. D. IMMS.

A Plain Man and a Mystic

(1) *Rural Rides.* By William Cobbett. Pp. xiv + 363. (2) *A Week on the Concord and Merrimac Rivers.* By Henry Thoreau. Pp. viii + 361. (Open-Air Library.) (London and Toronto: J. M. Dent and Sons, Ltd., 1932.) 3*s.* 6*d.* net each.

A FOREWORD by Mr. Fitch Daglish introduces us, in friendly fashion, to Cobbett and to those "Rural Rides" of which he wrote in his *Weekly Register*, a hundred years ago. He was sorely troubled by the "distressed state of the agricultural interest", all due (or so he says) to the "desolating and damnable system of paper money"; and this and what more he has to say on taxes and national debt sounds familiar to us, now that we are down again after a hundred years in the trough of an economic wave: "The system", he says, "seems to have fairly wound itself up; to have tied itself hand and foot with cords of its own spinning".

Cobbett was a good knowledgeable farmer, and his remarks on the farms by which he kept riding are vigorous and original. He always knew the soil below by the crops above, and badly farmed land or ill-kept cattle roused his contemptuous indignation. Courageous and prejudiced, he had that most useful political weapon, a knack of finding the appropriate and opprobrious epithet; and he seemed to have a personal interest in every cultivable inch of English soil. He was more than sixty years old when he rode those rural rides of his in all weathers, on a horse after his own heart, "tall, strong, gentle, and bold". He rode through villages and towns (or "wens", as he is fond of calling them) from Hants to Northumberland, welcomed everywhere by those "good and sensible men" who took in the *Weekly Register* and rang the church bells when he arrived. His many digressions are pointed and lively. He hates the agricultural monopolist, "the great bull-frog who takes all", neither more nor less than the city "tax-eaters and such vermin"; he loathes the teaching of the "barbarous and impious Malthus"; he has a pithy phrase always ready to hand, such as "a poor spewy gravel"; he admires the public spirit and political instincts of the race of cobblers; and on beholding the Oxford Colleges, he can't help thinking of "the drones they nourish and the wasps they send forth".

Cobbett's reaction to Nature was that of the eighteenth century, that of a disciple of Swift and of Voltaire. He thinks little of birds or of flowers; his interest lies with trees, and with those which are most useful to mankind. The unkempt but lovely larch "is fit only for burning". He was not insensible to beauty, but his appreciation of the country landscape was direct and agricultural. His spirit found freedom and well-being in the open air; and the familiar sights of farm and field, dear to him from childhood, stimulated his lively and curious intelligence to express itself in clear, easy, and trenchant prose.

Thoreau's "Week on the Concord" is another famous book of the open road, but its spirit is altogether different from that of the "Rural Rides"; it reflects the clean-cut and remarkable change of mood which is known as the romantic revival of the mid-nineteenth century. The two authors wrote under different inspirations, and besides, they were two very different men. Cobbett was a natural, warm-hearted, lovable, and exasperating man, with the reformer's aggressive sense of injustice, and with the usual accompanying touch of human vanity. Thoreau was a prig, self-conscious and philosophical; but his love of Nature and of books was genuine enough, if a trifle undiscriminating. He was a better naturalist than Cobbett and could write very pleasantly; but he was guilty now and then of execrable phrases and offensive sentimentality. Between the two men we become aware of

one of those complete changes of temper and of outlook which happen now and then in history. Human mentality itself seems to break down in a sort of emotional 'histolysis'; and the new generation can scarcely speak or understand the language of the generation before.

If we love quaint pieces of local history, scraps of folklore, and rambling disquisitions on philosophy, we may find them all in Thoreau. The angler will love his intimate pictures of "our finny contemporaries"; his leisurely descriptions of banks and woodlands will charm many a reader. The older naturalists of the countryside, lovers of the hedgerow and the open road like Cobbett and Thoreau, have been out of fashion for a while; and these pleasant books introduce us to them again.

L. STARKE.

Short Reviews

Men of the Trees: in the Mahogany Forests of Kenya and Nigeria. By Richard St. Barbe Baker. Pp. 283 + 31 plates. (London: George Allen and Unwin, Ltd., 1932.) 12*s.* 6*d.* net.

CAPT. BAKER is a forestry officer, not an anthropologist; yet his story of how he enlisted the services of the natives in conservation and afforestation work is an object-lesson in the practical application of knowledge of native custom and psychology to a problem in which the practice of the indigenous inhabitant ran counter to the end which the administration had in view. Probably Capt. Baker's object could not have been attained in any other way. An order framed to constrain native action might have been ignored or even disobeyed; and, in any event, it would almost certainly have led to friction.

From time immemorial, native methods of agriculture have been destructive of the forest. Small clearings are made, by fire and the machete, which are cultivated for a short time and then abandoned. The group—family or tribe—then moves on to another patch, and the process is repeated, the trees which have been destroyed not being replaced by planting. Capt. Baker secured the co-operation of the natives in his work of repairing the damage, and averting it in the future, by an appeal to their love of festivals and ceremonial dancing and their desire for social distinction through membership of a secret society or esoteric group. He formed a band of 'Men of the Trees', to which only the elect were admitted, pledged to plant and protect trees everywhere, distinguished by insignia, and owning its own special dance. Of its success we may leave the author himself to tell; but lest it may be thought that his story weighs as much against as for an anthropological training, as he was not an anthropologist, we hasten to add that his sympathetic understanding of the native is of an exceptional calibre.

This is indeed no scientific treatise on the forest trees of Kenya; but it may serve to spread among the general public a knowledge of the potential wealth of the timbers of the country if administered with care and skill.

The Taylor Series: an Introduction to the Theory of Functions of a Complex Variable. By P. Dienes. Pp. xii + 552. (Oxford: Clarendon Press; London: Oxford University Press, 1931.) 30*s.* net.

A POWER series of the form $\Sigma a_n(z-z_0)^n$ which converges at more than one point, converges inside a circle centre z_0 and coincides with the series obtained by applying Taylor's theorem to the sum-function. If another point z_1 is taken inside the circle of convergence, the function can be developed in a series $\Sigma b_n(z-z_1)^n$, which also converges inside a circle centre z_1, the area of which may extend beyond that of the original circle of convergence. An analytic function is defined by the original series and all possible transformed series obtained in this way. Since the coefficients b_n are obtained uniquely from the coefficients a_n it follows that the whole behaviour of the function must be determinate when the sequence of coefficients a_n is known. The problem of Taylor's series is therefore to deduce from a knowledge of the coefficients the behaviour of the function.

The first seven chapters of this book give the elementary properties of functions of a complex variable, ending with Jordan's theorem and a rigorous proof of Cauchy's theorem. These chapters are furnished with a variety of exercises. Chap. viii. discusses biuniform mapping and the theorems of Bloch, Schottky, Landau, and Picard. Chap. xi. deals with various means of representing a one-valued analytic function by an explicit formula. The problem of uniformisation is not discussed, as being beyond the scope of an introductory treatise. Chap. x. considers singularities and Chap. xi. overconvergence and gap theorems. Chap. xii. on divergent series gives a welcome and systematic discussion of generalised limits and sums. In Chap. xiii. this theory is applied to the Taylor series on its circle of convergence. Chap. xiv. discusses the relations between singularities and divergence.

The whole book forms a very useful introduction to the theory of functions of a complex variable, and the author is to be congratulated on the manner in which he has systematised such an immense amount of material in a way which is calculated to give a proper perspective of the subject. The printing is good, but the numeration of the paragraphs is not sufficiently prominent for easy reference.

A Manual of Beekeeping: for English-speaking Beekeepers. By E. B. Wedmore. Pp. xxiv + 413 + 8 plates. (London: Edward Arnold and Co., 1932.) 15*s.* net.

IN 1563, Thomas Hill wrote "A profitable instruction of the perfite ordering of bees". Since that time the stream of manuals for the use of English-speaking beekeepers has been continuous. The present work is intended as a practical handbook

for use in the apiary and is conveniently arranged for this purpose. To avoid needless repetition, cross-references are freely used, but not in such a way as to become exasperating.

The author has been wise in leaving matters of anatomy and physiology to books primarily devoted to those subjects. He is at his best when giving directions for the carrying out of some operation of practical beekeeping. His instructions are precise and to the point, and much of the information given is most conveniently tabulated. 'Manipulation' is a word beloved by beekeepers, and if a tithe of the operations here detailed were carried out, beekeeping would cease to be profitable, but the author gives us a timely word of warning: "*The skilled beekeeper is known by the small number and apparent simplicity of the manipulations he employs*". (The italics are his own.) Nevertheless, the directions for dealing with an emergency when it arises are to hand in these pages. The sections dealing with biological matters such as the underlying principles of swarming and the causes and diagnosis of bee diseases are less happy; while the lists of honey plants are necessarily sketchy and compiled from other sources.

The information given is intended to be generally applicable, and an attempt has been made to do justice to the conditions and practices of the honey-producing regions of Canada, New Zealand, and Australia.

The volume is singularly free from the expression of pet theories and prejudices such as mar so many books on bees. The figures are good and illustrate points in the text. The binding is of a practical and durable type, as it will need to be if the book is to be used in the way that is intended.

D. M.

Borstalians. By J. W. Gordon. Pp. 284. (London: Martin Hopkinson, Ltd., 1932.) 7*s*. 6*d*. net.

THIS is an interesting, useful, and on the whole well-written book. It appears at a time when outbreaks of crime, especially in the United States and to a certain extent in England, have made methods of prevention even more urgent than methods of detection and punishment. Mr. Gordon reveals with intimate knowledge and sympathy the methods employed now for a good many years at the five Borstal institutions in England. It is an encouraging picture, and being drawn with a frank and critical hand, carries the more conviction. He was himself an inmate at the Feltham Borstal and, having made good afterwards, largely through the interest and generosity of an American friend, was able to revisit the scenes of his early training, recall his own experiences, and note subsequent changes. He also visited the girls' Borstal at Aylesbury, and seems to have marched with the new colony which swarmed off a year or two back from Feltham to Lowdham. This forms one of the most attractive episodes in the book.

Criticising his own criticism, one is inclined to ask whether more might not be done in the way of stimulating intellectual interest, encouraging reading and providing classes and lectures, as well as the excellent work done by sports, games, badges, houses, etc. The girls seem to be better looked after in this respect. Perhaps women generally are less inclined to be frightened by the damning appellation of 'highbrow', a word and an idea that are doing a world of mischief.

F. S. M.

Breeding and Care of the Albino Rat for Research Purposes. By Milton J. Greenman and F. Louise Duhring. Second edition. Pp. 121 + 6 plates. (Philadelphia: The Wistar Institute of Anatomy and Biology, 1931.)

THIS book gives a clear and detailed description (with diagrams) of the housing, feeding, and behaviour of a colony of rats which has been in existence at the Wistar Institute for some twenty-four years. Thus the various points recommended are the result of much experimenting and long experience, which make them of real value, though some of the arrangements for housing appear to be unnecessarily elaborate. In addition, details of cages and water vessels, etc., in use and found suitable in other laboratories are given. Chapters on the parasites and diseases specially likely to attack the albino rat are also included. Special stress is laid on the advantages of 'gentling' the rats by frequent handling and of giving them opportunities for exercise, a point too often overlooked in breeding rats for experimental purposes. The importance, too, is emphasised of making full records of growth and fertility of the colony from time to time, so that any possible deterioration may be rectified.

The book will be of particular value to research workers who are starting a colony of rats, and it cannot fail to interest also those workers who may have a colony already established.

Theory of Simple Structures. By Prof. T. C. Shedd and Prof. J. Vawter. Pp. x + 345. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1931.) 22*s*. 3*d*. net.

SO many textbooks have been written on the subject of structural statics that it must have become a somewhat difficult matter to find any fresh aspect of presentation. The authors of the present work, however, very properly and consistently emphasise the application of fundamental principles to all constructional problems, and this attitude constitutes the keynote of their treatment. They deprecate merely graphical methods, which "have a tendency to leave the student with the memory of a method of construction and only a vague notion of the principles involved". Certainly, they have produced a very clear and concise exposition of the subject, which students should have no difficulty in assimilating, while the abundance of problems set provides an ample field for testing the knowledge acquired. Written by two American university professors, the purview of the photographic illustrations is largely trans-Atlantic, but the examples are interesting and helpful, while the diagrams generally are very clear and comprehensible.

B. C.

The Scope and Needs of Medical Research *

By Sir WALTER M. FLETCHER, K.B.E., C.B., F.R.S.

THE phrase 'medical research' covers an immensely wide field of scientific activity in which workers of many different kinds are occupied. It is concerned directly and indirectly with the welfare of the bodies and minds of human beings, and if properly treated it must be a subject of the first interest to any human audience. The word 'medical' in this relation is likely to mislead. Strictly it refers only to the healing of disease, and it calls to our minds at once a vision of doctors at the bedside and of their drugs or implements. Yet as we use it here it has a scope, not only in the work of original investigation but also in preparing its results for practical application, which is indefinitely wider than that of the healing profession as such.

I can give an actual definition of the real scope of medical research in formal terms. It is a formula which has been adopted by His Majesty's Government to define the field of medical research work to which an annual Parliamentary grant-in-aid is made, and it is in these terms: "Medical research deals with the proper development and the right use of the human body in all conditions of activity and environment, as well as with its protection from disease and accident, and its repair".

Let us take each phrase of the definition in turn. The development of the human body: here we have to consider both nature and nurture, both inheritance and nutrition. Dangerous as it is in scientific studies to separate these sharply in our minds, as is so often done, each, nevertheless, is served by a special scientific discipline. One is served by the science of genetics and the other by the science of nutrition.

The science of genetics is still in its first infancy. By an easy effort of imagination we can form almost illimitable hopes of betterment in body and mind that fuller knowledge in this subject may hold out to the human race. Dreams of this are so attractive and may be so vivid as to tempt us to propose short cuts to make them real. Hasty practical proposals made in the name of what is called 'eugenics' are put forward. Many of these are based on obviously false assumptions, as, for example, that particular parts of the community are not desirable breeding stock, merely because at present they are inadequately fed; or, again, that the qualities which make many men rich are the qualities which we should desire to multiply in our race. Quite apart from witless social prejudices of that kind, the very machinery proposed for attaining the results desired has often no basis at all in scientific knowledge. Yet in this field some of our highest hopes for man's future may still reside. We have evidence already that the knowledge we have gained of the laws and machinery of inheritance in the lower animals holds good for man. Small beginnings are being made already by the studies of selected pedigrees, the use of probability laws, the examination of correlations between characters either directly observable or detectable by refined methods of blood examination—all these give growing hopes of our being able to map out the distribution of factors in the human chromosomes, those minute carriers of inheritance in the parent cells. Medical knowledge has a leading part to play here, for the most hopeful clues now in sight depend upon closer medical study of the inheritance of disease and abnormalities in family history. We are in practice cut off from the method of experimental mating in the study of human inheritance, and must perforce use the methods of medical observation and analysis of pedigrees. The work in sight is vast and may occupy many generations. All the more important then that it should begin early. There is no short cut to the power for human welfare that we may hope some day to gain by genetic knowledge. The only road to this has to be cleared up by persistent effort in this primary branch of medical research.

The other side of the study of the development of man's body, that of nurture, lies in the field of nutrition, and here there is a very different story. This study is concerned in part with the quantitative study of the energy requirements of the body and in part with the qualitative values of diet. It has only been a branch of exact science for the last generation or two. Our knowledge upon the qualitative side, even of the very existence of the vitamins, so familiar by name now to all, belongs only to the last twenty years. Yet from the knowledge so far won in this field we have already gained practical powers of high value. I will return presently to this subject of nutrition to illustrate in more detail the value and interest of this part of the medical field.

Pursuing our definition, we now come, after dealing with the development of the body, to the problems of its right use—and its right use in all conditions of activity and environment. Here we deal with problems of personal hygiene, of sleep, of diet in relation to climate and to bodily activity. We have to deal also with an intricate group of problems belonging to industrial life. The industrial revolution and the introduction of machinery upon a great scale brought a host of new problems under this head. Individual craftsmen throughout the ages have found for themselves their own ways of working to the best effect, and of making the compromises needed for gaining the best output with the least fatigue and damage to health. The introduction of machinery and the gathering of workers into large factories came about with far too much regard to the welfare of the machinery and the magnitude of its output, and with far too little regard to the machinery of the bodies of the workers. The application of physiological knowledge in this field has been lamentably slow in coming. Most of the elementary problems of maintaining efficiency

* Friday evening discourse delivered at the Royal Institution on May 27.

in work and of the spells of rest needed for particular occupations of many kinds have been studied only within the present generation, after almost a century of waste, discomfort, and misery.

The War brought home to us our ignorance of this branch of medical study, though no other country had greater incentive, both in duty and in profit, to lead the way in its development. When the safety of our people depended upon the fullest output of war material and the maintained efficiency of the workers, it was found that we were ignorant, as a nation, of some of the most elementary laws of industrial health. We had to find and apply as best we could the optimum hours of work and the best use of rest pauses for different kinds of work, ranging from heavy physical labour to light manipulative tasks involving maintained attention to rapid machine processes. When the lives of men, or indeed of armies, might depend upon the rapid use of the spade in trench-warfare, it was found that nobody since Adam first used a spade had worked out the optimum rest-pauses for the best performance of a gang of digging men over different periods. Medical research had also to find new safeguards for men living in submarines below the sea, mining far into the earth, or flying to great heights in the air.

During and since the War, a great volume of research work has been done under the Industrial Health Research Board to clear up these problems connected with the right use of the human body. They deal with hours of work, heavy or light, rest pauses, shift systems, the problems of monotony in repetitive work; they have dealt with the human factor in the causation of accidents, with problems of ventilation, of lighting and heating, with all the special problems of vocational guidance and selection, with the study of body movements, posture, and physique in particular industrial processes, as well as with the special dangers arising from poisonous materials in particular trades or occupations.

We now come to the protection of the body from disease, and here we come for the first time to what is ordinarily thought of as medical work in its narrow sense. This part of the work falls, of course, at once under two main divisions. There is the work of preventing disease, and there is the work of curing or palliating disease when already present.

We can scarcely think, and have no reason to think, of disease as being caused otherwise than in one of three ways. There are diseases due to abnormalities of structure or chemical behaviour which are inherited and come from the genetic history of the individual. There are other diseases which are due to faults in the immediate environment of the body, early or late in its development, such as those, for example, known to be the result of imperfect nutrition. Lastly, there is a great variety of disease due to the direct attack upon the body by other forms of life in the shape of parasitic enemies.

We can aim at preventing inherited disease by increasing our knowledge of genetics and by regulating human mating. It will be very long before we have knowledge enough to gain much power in this direction, and how far we can use it when gained will depend upon our political structure and social habits. Already our genetic knowledge is enough to allow us to abolish at once one type of juvenile idiocy and greatly reduce other mental defects by regulation of marriages in the families displaying them.

Many diseases of environment are under our potential control already. Diseases like scurvy, beriberi, rickets, pellagra, are due to deficiencies of particular vitamins in the food. No doubt other abnormalities of body, including forms of mental weakness, will be found to be due to similar deficiencies, either in childhood or during embryonic life, and we know already, though not yet in enough detail, that deficiencies in diet diminish the resistance of the body to infective disease.

Lastly, we come to the great welter of disorders produced by the actual presence within the body of enemy parasites. These may be multicellular animals such as parasitic worms, unicellular forms such as the trypanosome of sleeping sickness, or the plasmodium of malaria; they may be bacteria, as in the infections of typhoid fever and pneumonia, or they may be minute bodies, barely visible by ordinary microscopes, which are the so-called 'viruses' causing diseases such as smallpox, measles, yellow fever, and so on. You have heard much of the great labours that have gone so far in giving us control over these enemies of our race, whether in tropical climates or at home. The work has involved clinical study of the diseases, intensive detective work to find out how the parasites are conveyed, whether by water, air, or soil, or by the intricate participation of insects and other carrying hosts. The study of these hosts and of the parasites themselves has been the work of zoologists in the field and in the laboratory, while the study of bacteria is a science by itself, with its specialised technical methods.

It is well known also that the knowledge gained here has already given us great powers in the prevention of disease, and an important part of the medical profession is devoted to their use in administration. I would only note here how random seems to be the relation of knowledge to power within this complex field. A very little knowledge of the infective agent concerned may give almost complete powers of prevention. We have the full power of preventing smallpox in any given man, or of distemper in any given dog, yet know much less about the nature of those viruses than about that of any other of the groups I have named. In malaria, on the other hand, we have a great deal of knowledge about the life history of the parasite and its mode of conveyance by the mosquito from man to man. We have the power of freeing any given community from the disease, but only if we have money enough to break the chain of events by getting rid of the mosquito carrier. We had this knowledge and this power a generation ago, yet there is more malaria in the world now than then, and it afflicts with its curse probably a third of the whole human race, with a death-rate of two million persons every year. What is needed now

is still more intensive research work that will allow us a more ingenious attack upon the parasite by methods which it may be practicable to use upon an immense scale at reasonable cost.

So much for preventive research. But protection from disease involves also its curative or palliative treatment; and here we come, for the first time, to the work of the medical profession as ordinarily understood, whether that of the physician or of the surgeon. When disease is beginning or has been established, the doctor is concerned to give his help in the most effective way to the single individual before him. This offers him an intricate set of problems which make his work a special branch of applied science in which high arts of skill are based upon the knowledge available. He cannot act effectively until he has found not only the nature of the disorder present but also its particular manifestations in that individual case. The very fact that he must avoid opening the body to look inside it has led to the development of intricate devices for observing and deducing the actual facts from the outside. I need not dwell upon the skill needed by the competent physician, nor upon the manipulative wonders now made possible to the surgeon by Lister's work: nor, again, need I do more than point to the high responsibilities undertaken by the physician or surgeon to whom a human life is entrusted. At every point their knowledge and skill depend upon the results of research work of many kinds, and their powers can only advance as research work progresses.

Lastly, there remains to consider, in the definition I am following, the protection of the body from accident, and its repair. The study of accidents has led to much profitable research work, of which some of the chief has been done under the Industrial Health Research Board. Accidents can be sorted out into those due to the unfitness of particular workers for given tasks, or to states of mind, or to conditions of fatigue and other states of the body, or, again, to the absence of proper protective devices and administrative rules. When their causation is accurately found, preventive work is at once rightly guided.

Under this last head, too, there is the skilled work of the surgeon in repairing physical damage done to the body. But we can only point to this here as completing our rapid survey of the whole campaign in the medical field. It is worthy of note that in coming to the end of this general story, we find ourselves close to the beginning of it again. Surgery has brought us near to the study of heredity again with which we started. For uncounted centuries the surgeon has repaired so far as possible the injuries of man's body in warfare and accident, and his chief concern has always been at least to prevent death by loss of blood. There is no more ancient surgical problem than that of whether a healthy man can lend some of his blood to save the life of another. Nearly three hundred years ago Dr. Lower of Oxford showed to King Charles II. and the early Royal Society that one dog's blood might be transfused into another dog to replace its own. But it has only been in the last twenty years that we have learned why it is that, while the blood of one man given to a patient who has suffered loss by bleeding may be fatal, that of another man may have no ill-effects and may restore life—and happily that knowledge came in time to save many thousands of lives in the War. Careful laboratory studies have shown that every human being belongs to one of four groups, distinguished by the different precipitating powers of their bloods, one against another. These subtle blood differences, far more subtle than any chemical analysis could detect, are of daily importance in surgery. They play a part also now in the study of human inheritance with which we began this survey.

(To be continued.)

Oriental Studies in the University of Chicago *

IN the past ten years the United States have made remarkable advances in archæological research in both the New World and the Old. In America itself the whole range of continental civilisation in one form or another from Alaska to Peru has been brought under investigation by university departments and public or semi-public institutions. In particular, the activities of the Carnegie Institution of Washington in Central America and of the Smithsonian Institution in the south-western United States have contributed materially to the advancement of archæological science through the intensive studies by means of which they are gradually filling in details of the chronological sequence in the development of culture in these areas.

In the Old World, both independently and in cooperation with European scientific bodies, American archæologists have extended their activities over a wide area. The American Schools in France, Athens, and Jerusalem and the expedition of the University of Pennyslvania, in conjunction with the British Museum, at Ur have achieved results of signal importance in the investigation of the history of man and his early civilisation. Less widely known, perhaps, but not of less moment, are the operations of the Oriental Institute of the University of Chicago, of which some account is given in a recent publication issued in commemoration of the opening of new buildings.

When the Oriental Institute was created by the trustees of the University of Chicago and organised by Dr. J. H. Breasted in 1919, its aim was to become "a research laboratory for the investigation of the early human career", and to trace "the course of human development from the merely physical man disclosed by the palæontologist to the rise and advance of civilised societies, the product of social and material evolution culminating in

* The Oriental Institute of the University of Chicago: in Commemoration of the Dedication of the Oriental Institute Building, Dec. 5, 1931. Pp. iv + 68. 25 cents.

social idealism ". It was felt that the proper field for its operations could be only the Near East, the region around the eastern end of the Mediterranean. The formation of the Institute was made possible by the generosity, first of John D. Rockefeller, jr., and then of a number of other benefactors. Field expeditions were sent out and the work of the Institute rapidly outgrew the capacity of its first headquarters in Haskell Hall. In April 1930, ground was broken for a new building, which was completed in April 1931. In this the work of the Institute is now installed and completely equipped for its threefold activities of work in the field, study in the laboratory, and the publication and dissemination of results.

In the field, the Institute now maintains twelve expeditions, engaged in collecting original evidence relating to the origin and development of civilisation. Of these, six are concerned with ancient Egypt, two with Iraq, and four are distributed in Anatolia, Syria, Palestine, and Persia respectively.

In Egypt the work of the six expeditions, though not all are engaged in actual excavation, is so distributed as to cover the development of Egyptian civilisation from the very earliest times to the nineteenth dynasty, or even beyond. The Prehistoric Survey under Dr. Kenneth S. Sandford of Oxford has made a detailed investigation of the Nile valley, finding the earliest evidence of man yet discovered in the Near East at the bottom of the gravels of the former Nile valley, and determining the date of the desiccation of North Africa and the formation of the Sahara. At Sakkara, the expedition under Prof. Prentice Duell has launched a programme for the complete record in five folio volumes of the great treasury of relief paintings in the masonry tombs of the cemetery of ancient Memphis. After nine years' work, Dr. Alan Gardiner and Dr. A. de Buck have completed the copying of the Coffin Texts from Middle Kingdom burials, which are essential for the study of the Book of the Dead. These are now being edited and will be published in a series of five volumes. In association with the Egypt Exploration Society, the Institute is saving the records of the beautiful temple of Seti I. at Abydos, "the loveliest works of art of the ancient world". These will also be published, mostly in colour, under the editorship of Prof. Gardiner, while the work is being carried on by Miss Amice M. Calverley, assisted by Miss Broome. Mrs. N. de G. Davies is also engaged in copying, in colour, paintings in the tombs of the great Theban cemetery. These paintings, together with series previously painted by Mrs. Davies for Dr. Gardiner, are to be published, the first volume appearing in 1932.

At ancient Thebes the Institute has its largest undertaking in the Near East, in the Epigraphic and Architectural Survey Expedition. The work of this expedition was begun in 1924–25, and with it is now combined the headquarter work of the Institute, for which a new building, in California-Spanish style, has recently been erected at Luxor. For seven years this expedition has been at work on the colossal temple of Medinet Habu and associated structures under Prof. Uvo Holscher. These excavations have revealed the surprising fact that the largest halls of the palace of Rameses III. had vaulted ceilings and were not flat-roofed as were the temples.

In Western Asia, as in Egypt, the work of the Institute has been planned on lines which are at once comprehensive and at the same time admit of expansion without danger of overlap and waste of effort. Two expeditions are working in the "Highland Zone" under the general direction of Dr. H. Frankfort. Four mounds are included in the concession which the Institute holds from the Government of Iraq. Of these mounds, Tell Asmar (Ashnunnak) is the most important. Here extensive headquarters have been erected. A large palace of Sumerian age has been discovered, of which the excavation is to be completed in the current year; while on another mound at Khafaji, about ten miles away, a large fortified enclosure with temples and dwellings has been uncovered. South of the "Highland Zone", where the cities and palaces of the Assyrians are important sources for evidence of a composite culture which draws its material from both north and south, the Institute is excavating the palace of Sargon II. at Khorsabad. Here Dr. Edward Chiera is following excavations begun by the French more than eighty years ago. Many valuable relief-sculptures have been discovered, including a huge winged bull, partly in the round, which, on the allocation of the Iraq Government, has been brought to Chicago.

In Anatolia, excavations on the Hittite city mound of Alishar in 1930 and 1931 have added this as the third of the sites on which clay tablets of Hittite cuneiform have been found. This expedition has done pioneer work in plotting the archæological levels, with the result that the careful listing and sequence identification of types makes available for the first time a history of the pottery in Hittite territory. A discovery of which the precise significance is as yet difficult to forecast is the apparent survival to-day of ancient Hittite speech in a small isolated village of Anatolia. It has been recorded by Dr. J. Mészáros, of the Angora Museum, and is to be published by the Institute.

In Syria, exploration has identified an ancient mound as the city of Calneh, to which reference is made by the prophets Amos and Isaiah as one of the Assyrians' greatest enemies in the west. A concession for the excavation of this site and a neighbouring mound has just been granted by the French authorities under their mandate. Headquarters are being erected and work will be begun on the two mounds simultaneously. The Palestinian expedition is occupied in the investigation of the city of Megiddo, one of the most important of strategic points in the history of the country. The Institute has recently acquired control of the whole site, an area of more than thirteen acres, and is now stripping off systematically stratum after stratum of the deposits. Up to the present, the expedition has descended to the stratum of the Hebrew kings. The finds included the stables in which Solomon kept the blooded horses imported from Egypt for

sale to the Hittites. An interesting innovation in the work on this site is the employment in air photography of a small captive balloon which carries a camera operated from the ground. Its use is fully described for the first time by Mr. P. L. Guy in *Antiquity*, June 1932.

A concession from the Persian Cabinet to explore and restore the palace of Persepolis has been inoperative until recently owing to lack of funds; but a generous anonymous donation has now made it possible to begin work. Dr. E. Herzfeld, of the University of Berlin, has been placed in charge of the excavation. As a preliminary, and in order to provide accommodation for the expedition, six chambers in the palace have been cleared. These chambers have afforded some interesting material, which *inter alia* indicates that they had once been part of the quarters of the harem of Darius.

Of the activities of the Institute in research and publication in Chicago, no more can be said here than that they keep fully abreast of the strenuous work of the expeditions in the field in dealing with the original material, and at the same time foster inquiry on other and cognate lines. Throughout its activities the characteristic feature of the work of the Institute is the breadth of vision with which its operations have been planned, combined with a singleness of direction towards the aim which was marked out for the Institute at its inception. It is scarcely necessary to indicate to what an extent in this, as in other matters, the Institute is indebted to its director, Dr. J. H. Breasted.

Obituary

M. Santos-Dumont

The death at São Paulo, Brazil, on July 23, of M. Alberto Santos-Dumont, at the age of fifty-nine years, removes another of the few remaining pioneers through whose efforts mechanical flight was achieved. Santos-Dumont was the first in Europe to make a public flight in a heavier-than-air machine, while his numerous experiments with dirigible balloons stimulated the progress of airship construction. His enthusiasm and intrepidity led him into many adventures, and his flights with small airships in the neighbourhood of Paris some thirty years ago made his name famous throughout the world.

Santos-Dumont was born on a large coffee estate at São Paulo on July 20, 1873, and it was during a visit of his family to France in 1892 that he began his work on dirigible balloons. By 1898 he was in possession of his first airship, and during the next few years he constructed about a dozen of various sizes, driven by internal combustion engines. With one of these, on Oct. 19, 1901, he made a flight from St. Cloud around the Eiffel Tower and back, in 29½ minutes, and thus secured the prize of 125,000 francs offered by M. Deutsch de la Meurthe. To commemorate the event, the Brazilian Government struck a special medal. The airship in which the feat was accomplished was of 22,000 cub. ft. capacity, and was driven by a 12 h.p. engine. During his experiments Santos-Dumont had many narrow escapes, and on one occasion had to be rescued from the roof of the Trocadero by firemen. His airships were all of the non-rigid type.

From the airship Santos-Dumont next turned to the aeroplane, then engaging the attention of the Voisins, Ferber, Archdeacon, Blériot, and others in France. Though familiar with the gliding experiments of Octave Chanute, little was yet known by workers in Europe of the aeroplane of the Wright brothers and of their historic flights in December 1903 at Kitty Hawk, South Carolina. By the beginning of 1906, however, Santos-Dumont had constructed a biplane with wings of box-kite form, and with this machine, on Aug. 22 that year, made the first public flight on record in the Old World. The same year he made other short flights. The machine was called *The Bird of Prey*. "Its main double-decker planes", wrote Miss Gertrude Bacon, "were tilted up at a considerable angle. There was no tail, but in front a big box-kite elevator; so that the thing appeared to fly tail foremost, or as someone said, like a duck with its neck outstretched. On a light, open framework in the midst, mounted on bicycle wheels, was the 50 horse-power Antoinette motor, driving the propeller at the back, and the sort of wicker waste-paper basket in which the aviator stood."

According to the *Times*, M. Santos-Dumont will be buried in the family vault at São Paulo, over which a monument will be erected identical with that set up some years ago at St. Cloud to mark his historic flight of 1901.

Prof. A. Humboldt Sexton

Prof. A. Humboldt Sexton died on June 21, at Jersey, at the age of seventy-eight years, after a long illness. He was the eldest son of Dr. George Sexton, who was well known in his time as a lecturer on spiritualism and later as a Christian apologist, and he was educated at private schools and the Royal School of Mines. He obtained a Royal Exhibition tenable at the Royal College of Science, Ireland, in 1871. In 1873 he became assayer to the Mining Company of Ireland, and in the following year was appointed chemist to the Broughton Copper Works.

Appointed science master to the Wedgwood Institute, Burslem, in 1881, in the following year Sexton became lecturer in chemistry and metallurgy at the Manchester Technical School. Two years later he was appointed professor of metallurgy at the Glasgow and West of Scotland Technical College, a position which he held until his retirement in 1909 with the title of emeritus professor.

Prof. Sexton was a past-president of the West of Scotland Iron and Steel Institute, and his numerous books on chemistry, metallurgy, and refractories were well known and much used in schools and colleges. He also published many papers in technical and scientific publications.

Upon his retirement, Prof. Sexton became Minister of the New Church at Jersey, and afterwards held a similar appointment at Liverpool and Northampton. He gave up the latter post in 1923 and returned to Jersey.

PROF. W. W. KEEN

PROF. WILLIAM WILLIAMS KEEN, who died on June 7 at the age of ninety-five years, gained his reputation as a surgeon during the American Civil War, and for a period of more than fifty years thereafter was recognised as the most outstanding figure in American surgery. He was a contemporary of Oliver Wendell Holmes, and like him had uncommon gifts of personality and scholarship. His textbook on surgery enjoyed a world-wide reputation for many years, and made his name known far beyond the University of Pennsylvania, in which he taught, and the city of Philadelphia, in which he practised.

Dr. Keen was one of the first to adopt and apply to surgery the principles and practice of Listerism. He was a scientific surgeon in so far as it is yet possible for a surgeon to be guided by scientific principles, and although the author of innumerable contributions to surgical literature, all of which added something to the subject dealt with, yet it was his personality and general proficiency rather than his originality in any particular field which gave him the high place he enjoyed for so many years.

Dr. Keen recognised that surgery depended for its advance on the growth of the basal subjects of medical education, particularly of experimental physiology, and never wearied in his defence of vivisection and of temperance. Like the late Sir William Osler, he was a bond between the medical professions of the United States and of Great Britain.

WE regret to announce that Miss Adelaide Ames, research assistant in the Harvard Observatory, was drowned in a canoe accident in Squam Lake, New Hampshire, June 26, at the age of thirty-one years. Her scientific work, thus suddenly ended, had already gained for her a wide recognition. She was a member of the Commission on Clusters and Nebulæ of the International Astronomical Union. For several years Miss Ames had carried on investigations in the field of extra-galactic nebulæ, her principal publications dealing with the Coma-Virgo cloud of galaxies. Her most important work was in connexion with a photometric survey of all extra-galactic objects to the thirteenth magnitude —a census of the inner parts of the metagalaxy to a distance of five to ten million light-years. This survey was completed in June and will be published during the next month in collaboration with Dr. H. Shapley.

WE regret to announce the following deaths:

Dr. Geo. K. Burgess, director of the U.S. National Bureau of Standards, and treasurer since 1924 of the National Academy of Sciences, on July 2, aged fifty-eight years.

Prof. Matthew Hay, emeritus professor of forensic medicine in the University of Aberdeen, formerly medical officer of health for the city, on July 30, aged seventy-six years.

Prof. John R. F. Sebelien, formerly professor of chemistry in the Agricultural College, Aas, Norway, known for his contributions to the chemistry of milk and dairy feeding and artificial manures, aged seventy-four years.

Sir William Willcocks, K.C.M.G., the distinguished irrigation engineer whose name is associated with the Assuan dam and the Assiut barrage in Egypt and with irrigation work in Mesopotamia, on July 28, aged eighty years.

News and Views

Dr. P. A. M. Dirac

DR. P. A. M. DIRAC, of St. John's College, Cambridge, has been appointed to succeed Sir Joseph Larmor when he vacates the Lucasian chair of mathematics at Cambridge on Sept. 30 next. Dr. Dirac has been one of the most notable of the group of young physicists (mostly within a year or two the same age) who have, during the past seven years, created quantum mechanics. After graduating at the University of Bristol both in engineering and in mathematics, he entered the University of Cambridge as a research student in the Faculty of Mathematics, and may perhaps not unreasonably be accounted fortunate in his time, for he was in the middle of his course for a research degree when the ferment of dissatisfaction with the limitations of the older quantum theory was at its height, and the great blaze of theoretical advance was set alight by Heisenberg's first paper of the autumn of 1925. Dr. Dirac was one of the first to see clearly how the new ideas were to be extended and formalised, and his own researches have played a great part in both these processes, especially in formalisation. His unpublished degree thesis was probably the first such attempt to present in any detail in a consistent and logical way the revolutionary new theory. Later he published a much expanded and revised form of this attempt in his well-known book on quantum mechanics. His most strikingly original and successful contribution to the whole theory is his relativistic theory of the electron, a contribution in which his great mastery of and instinct for form has guided him at once to the correct generalisation. Dr. Dirac will succeed to the Lucasian chair when he is just over thirty years of age, with the acclaimed consent and good wishes of all his colleagues in mathematical physics in Great Britain. His University may look forward to another long and distinguished tenure of a chair to which long and distinguished tenures are by no means unfamiliar.

New Skull from South Africa

PROF. DUBOIS' comment on the skull recently discovered at Ngandong, Java, and its relationship to Rhodesian man, which appeared in NATURE for July 2,

p. 20, enhances the interest with which anthropologists will await further particulars of the human skull which, it is announced, Prof. T. F. Dreyer, of Grey University College, Bloemfontein, has discovered at Florsbad hot springs. According to a message in the *Times* for July 27, Prof. Dreyer has found parts of a human skull and a tooth, associated with stone implements of a primitive type and the remains of extinct fauna on this site, which lies twenty-five miles north of Bloemfontein. The lower jaw is missing, but, it is said, most of the facial bones are present. The character of the skull cannot be determined with certainty until the base has been found; but Prof. Dreyer is reported to be of the opinion that it is that of either Neanderthal man or Rhodesian man. According to the measurement of the skull "over the eyes", it would hold a place intermediate between the two, the figure given being 130 mm., as against the maximum in Neanderthal man of 125 mm. and 139 mm. in Rhodesian man. These figures, slender evidence as they are, are certainly suggestive of the possible significance of the new find in relation to the affinities of early types of man in South Africa. Should it appear eventually that the skull is a second specimen of Rhodesian man, its association with stone implements and extinct fauna should provide the much desired evidence indicating the geological age and the culture of that remarkable type of primitive man.

Exhibition of British Archæology

An exhibition illustrative of recent field-work in British archæology was arranged at the London Museum in connexion with the International Congress of Prehistoric and Protohistoric Sciences which met in London on Aug. 1-6. Its primary object was to afford visitors from abroad some idea of the range and value of the material which archæological investigation in Great Britain is adding to the study of prehistoric and early historic times; but it was also intended to interest and inform other visitors to the Museum whose acquaintance with archæological studies might not be sufficiently intimate to keep them abreast with the activities of our research workers in the various provinces of the subject. The exhibits ranged from the pre-palæolithic discoveries of Mr. Reid Moir in East Anglia to the objects of late Saxon and Viking times from districts so far removed from one another as Durham and Dorset. The choice of sites illustrated was discriminating and the number of objects shown kept as low as possible, consistently with the aim of making the exhibition representative. It is, therefore, difficult to single out any one or two exhibits as especially worthy of note. Colchester and Verulamium naturally figured prominently, as also did Mr. A. Keiller's exhibit from the Windmill Hill site. No doubt many visitors were glad to avail themselves of Mr. Keiller's offer of admission to view the complete collection of finds shown at Charles Street, Berkeley Square. The interest of the exhibition was much enhanced by the magnificent series of photographs from the air of various classes of site which was lent by the Ordnance Survey and described in an admirable catalogue. An excellent descriptive catalogue was also prepared for the archæological exhibits. Probably it will be a long time before so completely representative a collection, drawn from widely distributed places of permanent exhibition, will be gathered together again.

Methods in Anthropometry

For a considerable period it has been apparent that the time was ripe for a measure of revision of the methods of anthropometry, although caution was enjoined by a not unnatural reluctance to take any steps which might lessen the value, for comparative purposes, of thousands of measurements taken by generations of anthropologists in the field and laboratory. The feeling of dissatisfaction with existing methods, however, both among British and Continental anthropologists, was sufficiently strong to warrant discussion; but it cannot be said that anything practical had emerged until recently, when certain suggestions were put forward jointly by Miss M. L. Tildesley, Dr. E. G. Morant, and Dr. L. H. Dudley Buxton as a report to the council of the Royal Anthropological Institute. Briefly, these suggestions are that for the moment there should be an agreed abbreviated technique of observations in anthropometry, confined to the racial characters of adults of both sexes; and that this should be determined and elaborated as required by an international committee. But it is put forward as a first step that a technique should be formulated for Great Britain and Ireland; and at the same time representative bodies in other countries should be invited to do the same for their areas, with the view of international discussion later. The proposal, with further suggestions as to detail, will be found in *Man* for July. While this courageous attempt to deal with a difficult situation scarcely calls for comment at the present stage, it may be pointed out that without an assurance of external support the proposal risks a great deal of wasted effort. British anthropologists cannot work in isolation, however considerable the proportion of their output in the world of anthropometric science may be.

Changes in Scientific Outlook

Sir Oliver Lodge on March 17 gave the oration at the thirty-sixth Foundation Week at University College, London. It was well received at its delivery, and is well worth reading in its published form (University of London Press, 1*s*. net). Sir Oliver is now so generally accepted as the best exponent of a tolerant, humane, and comprehensive way of regarding science that when he speaks, as he did, on "Changes in Scientific Outlook", he might expect an attentive audience. The address was eloquent, impressive, and highly stimulating to thought, but it scarcely covered the matter which the title would lead one to expect. There is little or nothing in it of the latest developments in science, the extension of specialisation, the connexions of astrophysics with laboratory work, the exploration of the border-line problems between animate and inanimate. Sir Oliver practically confined himself to the one issue which in his view outweighs in ultimate importance all the others, and the address might well be called "A Plea

for the Spiritual in the Realm of Science ". The spiritual in this case is not to be identified with the 'spiritual' which Sir Oliver has so closely and patiently pursued in the purely human sphere. He has, as always, a word on this topic, and pleads for the open mind, a plea which every fair-minded person will be willing to support. But he goes on to speak—and it is the burden of his speech—of the need of admitting a spiritual explanation of the phenomena of the world as a whole.

Spiritual Elements in Science

Sir Oliver is arguing throughout with those who maintain the strictly scientific or agnostic attitude, and in doing so he postulates what he calls " spiritual elements " or a " spiritual influence ", which at the end of his discourse he weaves into " the one Reality which gives meaning to the existence of the whole material world . . . and illuminates the whole universe with Immortal Love ". It is a fine passage, which takes us back to the triumphant finale of Dante's " Paradiso "—but one is bound to recognise that it is a supreme act of faith, an apotheosis of the Unknown rather than any extension of the scientific outlook. Science, *qua* science, will agree with Sir Oliver that the mere fact of the human mind attaining the power of prediction—forming, that is, scientific laws—proves that the universe, as presented to us, acts in an orderly or rational way. It will also agree with him that the progress of the human mind exhibits the development of truth, beauty, and love. But when he proceeds to evoke and apply these conceptions—as he frankly does—at any point in the story of evolution where scientific knowledge fails, one sees a danger and remembers the famous Hippocratic diagnosis of the sacred disease the 'sacred disease' was that of which men had not yet discovered the natural cause. Our religion should inspire and encourage, but, above all, it must not relieve us of the primary duty of following the truth into its most remote retreat.

World Agricultural Policy

The general assembly of the International Commission of Agriculture, which met at Lausanne on July 21–22, was attended by delegates from sixteen countries and thirty-five national agricultural organisations, and a statement has been issued on world agricultural policy. It was emphasised that the world agricultural crisis is due to the fact that production and the increased means of securing production have outstripped both present consumption possibilities and population increases, while purchasing power has meanwhile declined. The Commission therefore considers that a judicious organisation of production and exchange will constitute one of the most effective means for fighting the agricultural crisis and establishing the prosperity of nations on a new basis. The first step would be to substitute orderly marketing, through the agency of associated bodies or by means of systematic State-controlled quota import arrangements, for the present unregulated offers of large quantities of commodities on world markets. Simultaneously, all means of stimulating consumption in general will have to be considered. Efforts will have to be made to improve and regularise quality and to cheapen retail sale. An appropriate wages policy will have to be adopted which, while allowing of a decrease in the number of the unemployed, will take account of national purchasing power. The question of new markets should also be studied, and, for the time being, also that of the export of existing surpluses to countries where the populations are suffering from underfeeding or famine. Further, an increased consumption of products of animal origin would absorb a larger portion of the surplus of vegetable products, which would be transformed into milk and meat. Finally, building should be encouraged by all suitable means. The International Commission of Agriculture recommends agriculturists to support the work of international collaboration, to associate themselves with efforts which aim at the maintenance of peace, at guaranteeing the security of property, and at drawing closer the bond which unites economic groups and nations in a common interest.

International Scientific Centres in Paris

La Maison du Savant, which is to be built in Paris, will be a well-appointed meeting-place for French and foreign men of science, if the present plans come to fruition. Lecture rooms, restaurant, winter-garden, and other amenities will be at the disposal of members and visitors. In addition, it will possess an extensive office of information which will study projects for the erection of up-to-date laboratories and research institutions, and organise congresses, exhibitions, conferences, and all publicity necessary to attain the organisation's aims. An illustrated periodical will also be published eventually, to inform the public of the general progress of science. Other activities include a benevolent fund and the provision of scholarships. The Maison du Savant is under the patronage of M. Lebrun, President of the French Republic; it has received government support, and its honorary committee consists of a distinguished group of academicians, including MM. le Chatelier, Charcot, le duc de Broglie, Richet, etc. Its founder and president is M. Georges Lecuyer, president of the International Union of Decorative Arts, and its active director is M. Jean de Chappedelaine. The organisation hopes to raise fifty million francs in the near future for its extensive programme. Through the official support of the Chamber of Deputies and the Municipality of Paris, a beginning has been made with convenient office rooms at 5 Avenue de l'Opéra, Paris.

" La Maison Internationale de la Science " is a project put forward on the occasion of the Colonial Exhibition of last year, during an international congress of men of science and research workers, for the furtherance of their interests. Its temporary headquarters are at the Institut Marey, Avenue Gordon-Bennett, Paris. It has not been very active, owing to the absence of its director, M. Pélissier, on a government mission to the island of Réunion; in all probability it will join forces with the Maison du Savant. " Le Foyer International Universitaire " is a centre

planned by the University of Paris. It was to be housed in part of the hôtel de la Rochefoucauld d'Estissac; this, however, has been bought by the "Maison de la Chimie" (see NATURE, June 11, p. 865) for three million francs, which will be used by the "Foyer International Universitaire" to acquire another building in rue de la Four (the former École de Bouffémont). "Le Cercle Universitaire International" is a club projected by the Associations of University Students to receive visiting colleagues and university men and to organise meetings and lectures that will promote international friendship. Its president is M. Paul Langevin, and its temporary address is at the Musée Pédagogique, 41 rue Gay-Lussac, Paris.

Institut International de Documentation

THE eleventh Conference of the Institut International de Documentation (formerly de Bibliographie) will be held this year at Frankfort-on-Main on Aug. 30-Sept. 3. The Conference is open to all persons interested in the various aspects of documentation, that is, the collection, arrangement, filing, and indexing of graphic records. As in previous years, an attractive programme of papers has been arranged for presentation and discussion during the mornings, whilst the afternoons and evenings will be devoted to visits of inspection and recreation. The latter include visits to Darmstadt and Mainz, where State and municipal libraries will be inspected. The Conference fee of 12 R.M. includes all excursions. A special exhibition of technical appliances for library purposes (Adrema machines, photocopying apparatus, duplicating machines, metal furniture, etc.) has been organised in a room of the Conference building during the meeting. The programme of papers to be presented is not yet available, but copies of all papers will be distributed to members of the Conference prior to the opening session. Full particulars regarding hotels and accommodation and further details of the Conference may be obtained from the organising secretary, Dr. Schürmeyer, Direktor der Bibliothek für Kunst und Technik, Frankfurt am Main, or from the Secretary, British Society for International Bibliography, Science Library, South Kensington, S.W.7.

Sotheran's "Bibliotheca Chemico-Mathematica"

MESSRS. Sotheran, Ltd., have issued a first supplement to their "Bibliotheca Chemico-Mathematica" which was published in two volumes in 1921, and have again laid all students of science and technology under a debt of gratitude. The work pretends to be no more than a bookseller's catalogue, and does not, therefore, aim at completeness, but in fact it contains a most representative list of works, to the number of more than seven thousand items, of old writers in all branches of science, and a number of standard modern works. It is rendered of permanent reference value by the fact that the title-pages in the majority of cases are transcribed in full, and by the unusual wealth and scope of the notes that accompany most of the entries. One of the most interesting items (presumably to be sold as a whole) is a collection of more than eight hundred books from Newton's library, including copies of the first and second editions of the "Principia" with corrections, cancellations, and additions in Newton's handwriting—many of which were not incorporated in the later editions and would thus be of the utmost interest as showing the progress of Newton's thought—an annotated copy of Euclid, and many other works with Newton's autograph.

THE catalogue also includes a few books that belonged to Faraday and were bound and annotated by him, original copies of the first edition of Galileo's "Dialogo", a complete set of the Paris Academy's "Description des arts et métiers", with all its supplements, which is very rarely seen in the sale room—or the library—in its complete form, and, especially noteworthy, a copy of William Gilbert's "De Magnete", 1600, inscribed in what appears undoubtedly to be the autograph of the author, of which no other universally accepted example is known. The annotations are trustworthy and of great interest, and will save a great deal of searching through scattered authorities, the latest of whom appear to have been consulted. It is good to see that the title 'Honourable' is no longer given to Henry Cavendish, and it is to be hoped that Messrs. Sotheran's correction will finally destroy this persistent delusion. Prices appear to have risen since the date of the original catalogues, but remain moderate. Booksellers' catalogues are usually looked through rapidly for desired acquisitions, and if kept at all, are cut up for filing purposes, but the present volume is a bibliographical tool of value and should take its place beside its predecessors on the library shelf. It and the volumes still to come form a worthy memorial to the late H. C. Sotheran, to whom the volume is dedicated.

A New Periodical on Acoustics

THE rapid development of acoustics since the production of the thermionic valve is accompanied by so large an increase in the bulk of research papers that for some time the Acoustical Society of America has been publishing its own *Journal* devoted to the subject. A French journal, *Revue d'Acoustique*, is now to be published bi-monthly under the direction of a committee of well-known authorities. The first number, dated March 1932, wisely opens with a vocabulary, founded on that of the Committee on Acoustical Standardisation (*J. Acoustical Soc. of Am.*, **2**, No. 3), of acoustical terms with definitions and English equivalents, and authors are asked to indicate when they use a term with a different meaning. In addition to papers, abstracts longer than those usually available in *Science Abstracts* and a bibliography of papers and books published since 1925 are given. This latter section is classified under physiological acoustics, acoustic measurements, propagation, sound sources, sound receivers, music, mechanical music, noise and architectural acoustics, and books and general articles. The titles are given in French, with some inconsistencies of translation. Although a journal of acoustics will naturally be used

most by those interested in applied acoustics, several important general works published since 1925 might with advantage be included in the bibliography. The six books given are scarcely representative, sources in English being represented solely by the Physical Society's discussion on audition. A list of more than two hundred periodicals which are to be searched for the bibliography is given as a supplement. The address of publication is Les Presses Universitaires de France, 47 Boulevard Saint-Michel, Paris 5e.

Vocational Tests for School Children

THE City of Birmingham Education Committee has published the results of an investigation by E. Patricia Allen and Percival Smith into the value of vocational tests as aids to choice of employment (Treasurer's Department, Council House, Birmingham. 1*s.* net). Every child leaving school in Birmingham is carefully advised as to his future occupation, but it was felt that vocational tests might give the employment conferences more adequate data on which to base their suggestions. For the purpose of this experiment, the children leaving three schools were divided into two groups: one group was treated in the usual way, while the other was examined by special tests for manual, mechanical, and clerical ability, dress-making, and intelligence, and studies were added of social, medical, and temperamental conditions. The advice given was then based on the results. When the children had obtained work, there would be four categories, namely, the tested children who did and did not follow the advice, and the controls who did and did not. Evidence as to the progress of these groups in their industrial careers was then compiled over a period of two years. Although the report makes no extravagant claims, yet the general tendency was for the tested children, who were placed in accordance with the advice given, to be more satisfactorily placed than those in the other three categories. The writers report that a surprisingly large number of the parents had no ideas for their children, nor did the children as a rule know what they would like to do. The report is excellent, sufficient details being given, with the exception of the testing for temperament, to enable other workers to follow this up and use it for comparison. The results are in agreement with the previous London research.

Tung Oil in the United States

THE establishment of the tung oil industry in the United States has been so successful during the last few years that a move is now being made to expand it on such a scale that America will cease to be dependent on China for even small quantities of this commodity. Dr. H. A. Gardner has recently described the position in a paper before the American Chemical Society (Science Service, Washington). Tung oil is essentially an oriental product, used through the ages by the Chinese for making native lacquer and ink. It is manufactured from the seeds of a deciduous tree, *Aleurites*, native to China, on much the same principle as peanut oil is produced by milling from peanuts in that country. Seeds were first introduced into America through the agency of the U.S. Department of Agriculture in 1905, and planted at the Government Experimental Station then at Chico, California. Extensive plantings, however, were not made until some eight years ago in the southern States, which were so successful that already 25,000 acres of land have been given over to the industry. The American Paint and Varnish Association is particularly concerned with this venture, as the oil is a valuable ingredient of varnishes and varnish paints. Apart from those uses, the American industries have extended considerably the application of tung oil, and it is now employed in the manufacture of insulating compounds, brake linings, linoleum, waterproofing fabrics, as a binder for wall board and plastic synthetic lumber, primers, synthetic resins, battery jar compounds, aeroplane tubing fillers, and so on.

American Institute of Physics

FOR several years, a movement has been on foot in the United States to bring about co-operation between the several American societies devoted to physics and its more immediate branches. This has recently had its culmination in the formation of the American Institute of Physics, comprising the American Physical Society, the Optical Society of America, the Acoustical Society of America, the Society of Rheology, and the American Association of Physics Teachers. The purposes of the Institute are subject, of course, to natural development in accordance with the future needs of its founder societies. For the present, its principal activity is the publication of journals. The societies are delegating to the Institute the responsibility for publishing the journals which they have in the past sponsored themselves. The reason for this course of action is the promotion of economy and efficiency. The list of the journals includes the *Physical Review*, *Physics*, *Reviews of Modern Physics*, *Journal of the Optical Society of America*, the *Review of Scientific Instruments*, *Journal of the Acoustical Society of America*, and *Journal of Rheology*. The scientific editing of the journals remains the duty of the societies, while all the details in the handling of proofs, subscription records, book-keeping, and the like are undertaken by the Institute. Two important other functions have been assigned to the Institute, namely, the further co-operation with societies and agencies outside the founding group, and the extension of an information service to the Press. The central office of the American Institute of Physics is at 11 East 38th Street, New York City.

Manufacture of Insulators

THE *Vista* is a periodical published by the British Porcelain Co., Ltd., London, S.W.1, and deals mainly with subjects of interest to the electric power industry. In the May number it concludes a series of articles on insulator manufacture. Each piece of electrical porcelain is carefully inspected by factory inspectors immediately after removal from the kiln, and all pieces failing to pass this inspection are destroyed. To find the porosity, fragments of the porcelain are

placed in fuchsine dye and subjected to a pressure of two thousand pounds per square inch for twenty-four hours. They are then removed, carefully dried, and broken to find out whether there is 'penetration' or not. If any is noticed, the representative batch of insulators is destroyed. The thermal test consists in immersing the porcelain in boiling water and then in iced water for periods of ten minutes, one hot and one cold test constituting a thermal cycle. After five such cycles, the porcelain is flashed over to test for thermal failure. After further thermal cycles, the insulators are subjected to a flashover test. They are next subjected to a flashover test at a frequency of 250,000 cycles per second. This test has proved a boon to the industry, as it eliminates porcelain with dielectric defects. In assembling the insulators, Portland cement with a definite proportion of pure water is used. They are allowed to stand five days before being cleaned and treated with weather-proofing compound, and after three more days a routine tension test is applied. The final tests are made in the presence of the customers' inspector, who sees the large completed insulator subjected to a load of 10,000 lb. weight and to a high-frequency flashover.

The Census of India

In a paper read to the Royal Society of Arts on June 3, Dr. J. H. Hutton discussed some of the figures of the Indian census of 1931. Perfect accuracy in enumeration is not to be expected, and in this census there were certain unusual difficulties. From estimates based on those regions where the census was known to be incomplete for reasons that can be traced, it may be assumed that the deficiency for the whole of India is not more than one per mille. It was calculated that the normal increase in the decade 1921–31 should have been 8 per cent, or rather less if allowance were made for the last influenza epidemic and its inroads on population of the reproducing age. The actual increase, however, proved to be 10·6 per cent, a rate exceeding any previous record. The increase was greatest in the Native States and apparently has been most marked in the less fertile parts of the country, which is an indication of the pressure on agricultural land. In some cases, heavy increases have been due to an extension of irrigation. The lowest density came from certain districts of Baluchistan and the highest from part of Cochin, where the density exceeds even that of Java. There has been little change in the general proportion of urban to rural population. In 1931 the total percentage of urban population was 11·0 per cent as compared with 10·2 per cent in 1921. The proportion of females to males is falling and is now 940 females to every 1000 males.

Announcements

The Medical Research Council has appointed Mr. Ernest Bevin, Dr. C. G. Douglas, and Mr. W. S. Morrison, M.P., to be members of the Industrial Health Research Board in succession to Mr. Arthur Pugh, Prof. E. P. Cathcart, and Major A. G. Church, who retire by rota on Sept. 30.

At the quarterly *comitia* of the Royal College of Physicians of London held on July 28, the Bisset Hawkins Gold Medal was awarded to Dr. T. H. C. Stevenson for his work as superintendent of statistics in the office of the Registrar-General. It was also announced that the Harveian Oration will be delivered by Sir George Newman, Chief Medical Officer of the Ministry of Health and Board of Education, on Oct. 18.

At a meeting of the Council of the North-East Coast Institution of Engineers and Shipbuilders, held on July 22, the following medals were awarded: the Engineering Gold Medal to Messrs. L. J. Le Mesurier and R. Stansfield, for a paper entitled "Combustion in Heavy Oil Engines"; the Shipbuilding Gold Medal to Dr. F. H. Todd, for a paper entitled "Some Measurements of Ship Vibration"; the Thomas Fenwick Reed Medal, "for ability to take a share in the control of industry", to Mr. W. Spencer Paulin. The first Andrew Laing Memorial Lecture of the Institution will be delivered on Oct. 28, by Eng. Vice-Admiral Sir R. W. Skelton, Engineer-in-Chief of the Fleet.

It was announced at the annual meeting of the Wiltshire Archæological Society, which was held at Malmesbury on July 26, that the outgoing president, Mrs. M. E. Cunnington, in conjunction with her husband, Capt. B. H. Cunnington, had offered the nation the now famous prehistoric sites of Woodhenge, near Stonehenge, and the Sanctuary, near Avebury. These sites were purchased and excavated by Capt. and Mrs. Cunnington after their discovery from the air. They have since been fenced and the ring of post holes, in which the wooden, and in the latter wooden and stone posts, formerly stood, marked by low concrete pillars, showing the plan of the monuments. This generous offer has been accepted by the Office of Works.

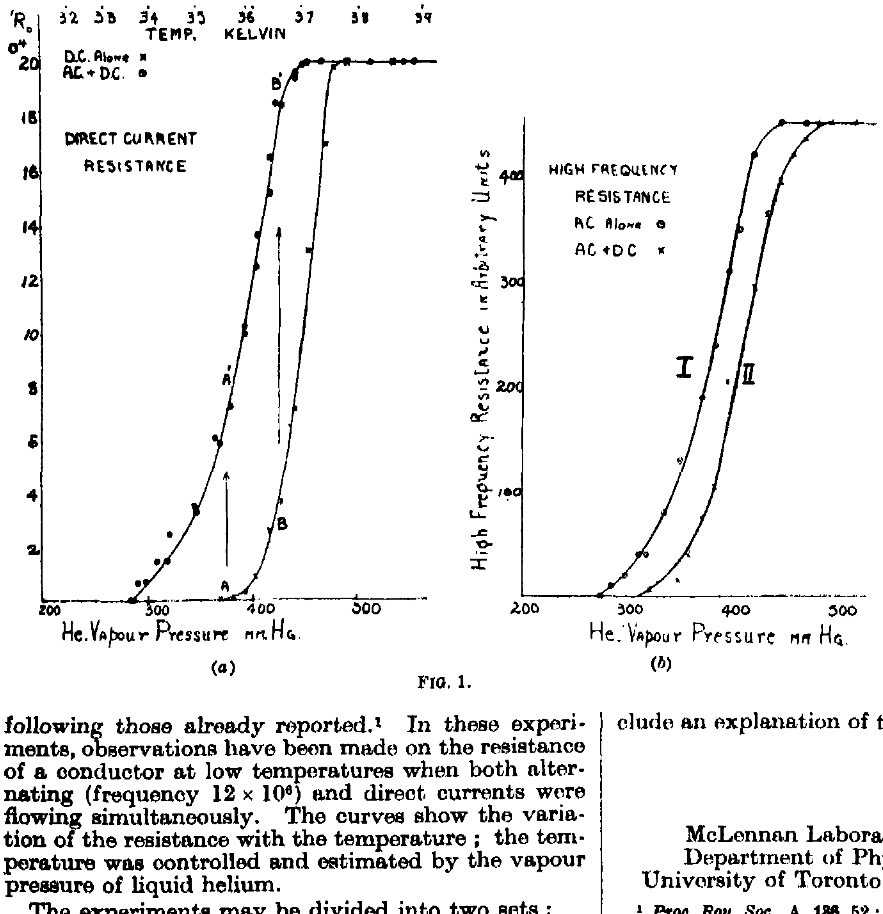
Applications are invited for the following appointments, on or before the dates mentioned:—An assistant lecturer and demonstrator in civil engineering at the University College of South Wales and Monmouthshire, Cardiff—The Registrar (Aug. 8). An assistant for abstracting scientific and technical papers at the Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1.—The Secretary (Aug. 8). An assistant engineer in the Harbour Engineer's Department, Colombo Port Commission, Ceylon—The Crown Agents for the Colonies, 4 Millbank, Westminster, S.W.1 (Aug. 8). A curator at the Art Gallery and Museum, Doncaster—The Town Clerk, Town Clerk's Office, Doncaster (Aug. 9). Junior scientific officers in the Scientific Research Pool, Air Ministry—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (Aug. 18). An engineering assistant for the Portsmouth Water Company—The Engineer, Water Company's Office, 26 Commercial Road, Portsmouth (Aug. 22). A principal at the Kadoorie Jewish Agricultural School, Mount Tabor, Palestine—The Chief Secretary to the Government of Palestine, Jerusalem (Aug. 30).

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Superconductivity with High-Frequency Currents

FURTHER experiments have been carried out by us in this laboratory on the phenomena of superconductivity with alternating currents of high frequency, following those already reported.[1] In these experiments, observations have been made on the resistance of a conductor at low temperatures when both alternating (frequency 12×10^6) and direct currents were flowing simultaneously. The curves show the variation of the resistance with the temperature; the temperature was controlled and estimated by the vapour pressure of liquid helium.



(a) (b)

FIG. 1.

The experiments may be divided into two sets:

(a) The resistance offered to direct currents by the metal (tin) was measured both with and without accompanying high frequency currents.

(b) The resistance offered by the same sample to high frequency currents was measured both with and without accompanying direct currents.

The resistances of the conductor to direct currents and to high frequency currents were measured by independent methods, as indicated in the paper referred to above.

The results may be stated thus:

(1) (Fig. 1 (a)). Curve *AB* represents the relation of R/R_0 and temperature (Kelvin) for direct current. When, in addition to the direct current, high frequency currents were induced in the same conductor, the resistance to the d.c. changed so as to shift the curve towards lower temperatures (*A'B'*). The switching on and off of the high frequency generator changed the resistance reversibly from the point *A* to *A'*, from *B* to *B'*, and so on. The position of the displaced curve was found to depend upon the ratio of the magnitudes of the high frequency to the direct current in the specimen. When this ratio was decreased by decrease of the induced high frequency currents or by increase of the direct current, curves were obtained lying between those shown in the graph.

(2) (Fig. 1 (b)). Curve I represents the relation of the high frequency resistance and the temperature. When, in addition to the alternating current, direct current was applied to the specimen, curve II resulted.

When both currents were flowing, the critical point for the high frequency resistance was the same as the critical point for the direct current resistance; the position of this common critical point on the temperature scale is determined by the ratio of the magnitude of the direct to that of the alternating current. Thus, when the superconducting state had been established at this common critical temperature, resistance was offered neither to direct nor to alternating currents.

Two effects have therefore been established, the depression of the critical point for the direct current resistance by the application of high frequency currents, and the raising of the critical point for the high frequency resistance in the presence of a direct current. Full details of the experiments are in preparation for publication elsewhere.

These experiments confirm the reality of the frequency disturbance of the superconducting point found in our early experiments, and it follows that any theory of the nature of superconductivity that may be advanced must include an explanation of this new phenomenon.

Inter-Diffusion of Metals

WE have recently applied high precision X-ray analysis to the study of the inter-diffusion of two metals in the solid state. Although the experimental work so far has been confined to mixtures of copper and zinc particles (heated *in vacuo*), enough data have been obtained to show that this new method has distinct advantages over the methods hitherto employed, and that it admits of wide application. Its two principal features are: (a) the direct measurement of a fundamental quantity, namely, lattice parameter (or mean atomic volume), while, in other methods employed to study this phenomenon, mean values of such quantities as chemical composition, width of zones, electric resistance, thermoelectric effect have been determined; and (b) each phase present at any time gives its own X-ray reflection lines independently, from which its composition can be readily found from standard composition-parameter curves.

In Fig. 1, a series of prints from portions of X-ray

photographs is reproduced, in which the trend of inter-diffusion in a 70 per cent copper-zinc mixture, at 450° C., can be followed, for diffusing times varying from 10 minutes to 140 hours. The reflection lines from the different phases are clearly shown. During the early stages in the production of a phase, lattice distortion usually causes the reflection lines to be broad and unresolved; but while the accuracy attainable in the mean parameter measurements is thereby somewhat impaired, it is considered that the composition derived from such measurements is still accurate enough for the present purposes. It may be added

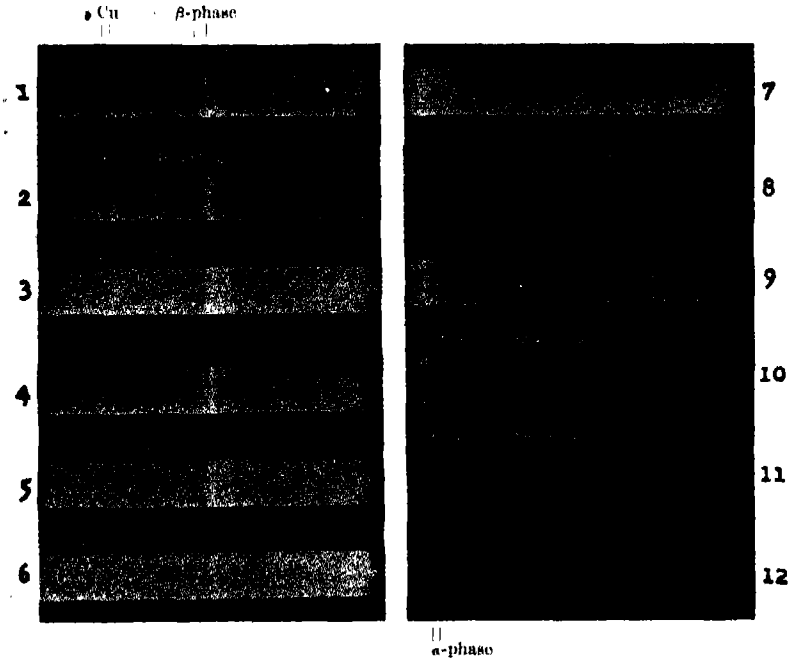

FIG. 1.—X-RAY PHOTOGRAPHS OF MIXTURES OF FILINGS OF COPPER AND ZINC CONTAINING 70 PER CENT COPPER HEATED AT 450° C. FOR DIFFERENT TIMES

Photo. No.	Time of Diffusion.	Parameter (in A.).			Photo. No.	Time of Diffusion.	Parameter (in A.).		
		Copper.	β-phase.	α-phase.			Copper.	β-phase.	α-phase.
1	10 min.	3·6079	2·947	—	7	8 hr.	—	2·943	3·688
2	¼ hr.	3·6079	2·945$_6$	—	8	12½ hr.	—	—	3·686
3	½ hr.	3·6079	2·944$_6$	—	9	18 hr.	—	—	3·685
4	1 hr.	3·6079	2·943$_8$	—	10	45 hr.	—	—	3·680$_1$
5	2 hr.	3·6079	2·943$_7$	—	11	70 hr.	—	—	3·679$_7$
6	4 hr.	—	2·943$_3$	3·69$_8$	12	140 hr.	—	—	3·674$_3$

Parameter of 70 per cent Cu-Zn Alloy = 3·674$_1$

that the precision measurements are capable of giving parameter values to at least 1 in 4000, with good reflection lines on the most unfavourable positions on the film.

From a study of various series of data, similar to that in Fig. 1, there appears no doubt that the inter-diffusion of copper and zinc is entirely controlled by the thermal equilibrium diagram, the rate of diffusion in the various phases being different. Consequently, while our investigations had initially in view the study of the general laws of inter-diffusion in the solid state, it was realised that the copper-zinc system was too complex to attain the object satisfactorily.

The data obtained by using particles of different graded sizes showed, however, that the rate of diffusion at a given temperature was independent of particle size. Also, the fundamental law of inter-diffusion appears, and is put forward tentatively here, to be of the form $c_0 - c = \Sigma K e^{-mt}$, where c is the composition at time (t), c_0 the final composition, and K and m are constants depending upon the temperature at which inter-diffusion takes place, each phase present having a different set of constants. This relation is different from Weiss's law,[1] $dc/dt = 1/t$, which Ageew and Vher claim to have demonstrated experimentally.[2]

We hope to publish shortly a detailed account of this new development and the data obtained. At present, an investigation into the inter-diffusion of copper and nickel is being carried out by the method, as we anticipate that this latter system, owing to its simple solid solution constitution at all compositions, will eliminate certain complications and yield more definite and conclusive experimental data as regards the fundamental law of the inter-diffusion of metals in the solid state.

'Protective' Adaptations of Animals

I AM sure that B. P. U. would not willingly misrepresent the opinions of those with whom he disagrees, yet he has done so when he refers to the existence of a common belief "that anything found in a bird's stomach would be in an unrecognisable state"[1]. I do not know of any naturalist who holds this opinion. B. P. U. has apparently extended into this sweeping statement the conclusion that the remains of butterflies eaten by birds soon become unrecognisable as Rhopalocera, except with the aid of the microscope. The history of this conclusion is interesting. In W. L. McAtee's earlier paper, "The Experimental Method of Testing the Efficiency of Warning and Cryptic Coloration in Protecting Animals from their Enemies",[2] the following statement appears:

"Practically the only large body of authentic information on the natural food habits of birds is contained in the records of the United States Biological Survey. They comprise detailed identifications of the contents of more than 48,000 bird stomachs, representing all families of birds and collected in hundreds of localities in the United States at all seasons. The United States has a goodly representation of butterflies, yet only five of these 48,000 stomachs contained remains of Rhopalocera."

About the time when this paper was published, certain distinguished naturalists in Great Britain expressed the concurrent opinion that birds rarely attacked butterflies, and some of them stated that they had never, in all their experience, witnessed such an attack. Accordingly, those other naturalists who, on various grounds, had come to the conclusion that birds are the chief selective agents in the evolution and maintenance of butterfly mimicry, set to work to test the value of this negative evidence as well as the trustworthiness of McAtee's "authentic information". The result has been, in the first place, the accumulation

of a great body of direct and indirect evidence, and in the second, the proof, by C. F. M. Swynnerton and W. A. Lamborn, that butterflies, after being eaten by birds, are soon rendered unrecognisable save by the use of the microscope. The further result has followed that McAtee, although he attempts no explanation or defence of his earlier figures, now records the remains of butterflies (24 in the larval, 2 in the pupal state), in 113 out of 80,000 stomachs. To search with the compound microscope for butterfly wing-scales scattered through the contents of 80,000 avian digestive tracts would be a serious business, and if it had been accomplished I venture to believe that far more positive results would have been obtained.

Apart from butterflies and moths and some other specially delicate forms, it is well known, and, so far as I am aware, has never been disputed, that the group and sometimes even the species of insect is readily recognisable when present in a bird's stomach.

It would be inconvenient, within the scope of a letter, to make any further comment on McAtee's two papers and on B. P. U.'s other conclusions founded upon the second.[3] A detailed reply, now in course of preparation, will, it is hoped, appear in the near future.

EDWARD B. POULTON.

Oxford University Museum,

[1] NATURE, July 9, 1932, p. 66.
[2] *Proc. Acad. Nat. Sci.*, Philadelphia, June 1912, p. 281.
[3] Smithsonian Miscellaneous Collections, vol. 85, No. 7, p. 201. Washington, 1932.

B. P. U.'s article on "The Value of 'Protective' Adaptations of Animals" in NATURE of July 9 demands some comment. The issue can only be finally settled by *ad hoc* experimentation; there has already been a certain amount of this, and on the whole it has given evidence of discriminative rejection of certain types.

That, however, can be dealt with by those more familiar with the details of the work than I am. I would here only like to point out what I believe to be a fundamental fallacy in the conclusions summarised by B. P. U.

The arguments put forward appear to be threefold:

(1) The number of insects found in birds' stomachs is proportionate to their numbers in Nature. The proportionality, however, is admitted to be rough only.

(2) Even groups which are usually said to be specially protected are eaten. "Some birds eat ants in very large numbers."

(3) Some organisms which are known to be poisonous are freely eaten, though this causes the death of their captors.

With regard to the first point, it is, I think, relevant to point out that if an inquiry were held we should doubtless discover that the number of ships of different type which are wrecked are *roughly* in proportion to their numbers, whether they are equipped with Diesel or steam engines, with this or that type of steering gear, this or that type of compass. Again, the number of war vessels of different types sunk by enemy gunfire during the War would doubtless prove to be roughly proportional to their numbers, irrespective of the thickness of their armour-plating. So long as the proportionality is rough, such facts have no relevance whatever to the question of whether the armour-plating, the type of compass, etc., have functional value for navigation. Even if the proportionality were exact, it would have little significance. All ships have to be 'adapted' to navigation in a number of ways if they are to survive the dangers of the sea at all: those that are 'worse adapted' in regard, for example, to compass or power, deliberately do not take such risks as others, but stick to coastwise traffic, and do not put out when 'better adapted' boats would not hesitate: their 'adaptation' is in their habits.

So with organisms. They all have to be adapted in a thousand ways if the species is to persist. With regard to avoiding their enemies, some do so by stressing protective coloration, others by protective and retiring habits, others by high fecundity, others by distastefulness, others by toughness, others by speed, etc. The avoidance of enemies is never perfect; but this does not in the least invalidate the fact that to achieve survival numerous adaptations have been necessary. We should also remember that a certain number of protectively coloured animals will of necessity be discovered, a certain number of warningly coloured ones eaten. The absolute number, and also the proportion, will increase with (*a*) the abundance of the species itself, (*b*) the hunger of the enemy species. This mechanism helps to produce the rough proportionality between abundance and number eaten; but it tells us nothing as to whether the total abundance would not have been quite different if the colour were not adaptive.

One has only to imagine an organism which was conspicuous in colour and in habits, sluggish, palatable, juicy and soft, and with a low fecundity. How long would the species survive? I take it, about as long as a type of ocean-going ship with no compass or steering gear.

A species is only adapted *to survive*, not to become immune from all enemies (which would, in any case, lead to destruction through over-multiplication); and each adaptation is relevant only in its particular way.

As regards point (2), it is a well-known fact that adaptation for protection is frequently met by counter-adaptation for attack. The fact that "some birds" (B. P. U.'s own words) eat ants freely does not imply that ants are not rejected, relatively or entirely, by most birds. To deny this is like denying that submarines are particularly immune from detection by most ships, on the ground that by special methods they can often be located and destroyed by depth charges.

Point (3) may or may not mean anything. Without precise investigation directed especially to the ecology of the species, it is impossible to say whether or not the poison or the distastefulness may not actually confer protection against other organisms than those which do eat them. This is really a variant of the answer to point (2). Some plants are in general poisonous, and appear to be therefore immune from being used as food by most insects; but they are eaten by insects which possess a special immunity (cf. certain Papilios).

In general, the fallacy is that of forgetting that no species of organism could exist which was not a bundle of adaptations, but that each particular adaptation is partial and relative.

Degenerative Mutations

IN Mrs. Sexton's important paper [1] on "Degeneration and Loss of the Eye in the Amphipod *Gammarus chevreuxi*" she makes one remark which, in its suggestion of theoretical controversy, is in striking contrast with the mass of details of observation, and minute records of genetical facts, of which the rest of the paper consists. The sentence to which I refer is: "In view of all that has been written on the origin of the blind fauna, it is a significant fact that blind animals could be produced within the limits of a single species in such a short time and in so few generations".

This means, apparently, that the blindness of cave

animals has not been gradually evolved under the influence of darkness, but is the result of degenerative mutations of the same kind as those described in Mrs. Sexton's paper. She describes a series of retrogressive mutations, red-eye in 1912, albino-eye in 1915, 'spotted', and one-eye and no-eye in 1920. The absence of one or both eyes occurred among the descendants of a single mating in which the three earlier mutations were combined. In the latest degenerations, the shape of the head was frequently altered; in some cases the first antennæ were absent, the shape of the brain was abnormal, and finally there was a marked degeneration in the reproductive organs, many individuals being sterile and others intersexual. No such progressive degeneration in many directions has been shown to occur in the blind Crustacea or blind animals of other classes in the cave fauna, or in *Gammarus chevreuxi* itself in the wild state.

I would suggest that Mrs. Sexton's stock of *G. chevreuxi* offers a much closer and more obvious analogy to Japanese goldfish in their monstrous abnormalities than to blind cave animals. In both the former cases, the degenerative mutations occur in animals kept in close confinement under abnormal and unhealthy conditions, and it seems reasonable to conclude that such conditions are the real cause of the so-called mutations. Vigorous and normal development depends on normal conditions. The normal genes do not live a charmed and invulnerable existence; the evidence suggests that they are altered and enfeebled by confinement, by impurities and deficiencies in the surrounding air or water and in the diet, by want of exercise, with the result that in the course of generations their power to determine normal and vigorous development is enfeebled and all kinds of deficiencies and abnormalities appear and increase until the strain dies out. As Mrs. Sexton herself says, "the farther removed from the normal an animal is, the lower its viability".

Thus it seems to me that the significant fact is, not that blindness may be produced without the influence of darkness and that therefore the blindness of cave animals has not been due to the absence of light, but that degenerative and hereditary mutations are caused by the abnormal conditions involved in keeping animals confined in small vessels inside a laboratory for a long series of generations, and that further degeneration is produced by combining such mutations by interbreeding.

Cytological Differences between Closely Allied Species

IN 1931 [1] I described important differences between the watery, neutral, red-staining vacuoles of the eggs of *Rana tigrina* and *Rana cyanophlyctis*. For details references may be made to the original paper, but the most important difference is in the size of the vacuoles, those of *tigrina* measuring as much as 0·02 mm. in advanced oocytes, whereas those of *cyanophlyctis* are very much smaller.

In the course of certain experiments carried out last summer on the eggs of a large number of animals with Sudan III. and Scharlach R. to determine the exact time when the lipoidal Golgi elements become fatty, it was discovered in *R. tigrina* that the fatty yolk, which had been reported by me in 1931 to be absent in the biggest egg (1·08 mm.) then studied, actually puts in its appearance when the egg measures 1·2 mm. From this stage up to 1·5 mm. (the biggest egg I have ever examined in this species) the fats stain deeply with the above dyes, but no red granules appear in younger oocytes. In *R. cyanophlyctis*, on the other hand, the Golgi elements become fatty when the oocyte measures a little more than 0·5 mm.

In 1931 I sounded a note of caution as to "how discordant results can be arrived at by two workers investigating two species of the same genus". I added that "if I had not first studied the big vacuoles of *tigrina* I might have perhaps failed to notice those of the other species. I imagine that the British and European frogs in which no vacuoles have been described are like *cyanophlyctis*."

That is exactly what has actually happened. Prof. Saguchi,[2] working on the eggs of *Rana nigromaculata*, confirms most of my conclusions, but finds that there is no vacuole and that fat appears when the egg measures 0·3 mm.

I would like to recommend the eggs of *R. tigrina* to all teachers in India running cytology courses for demonstrating the Golgi elements, the mitochondria, and the vacuolar system in fresh oocytes without the aid of any vital dye. The most favourable stage for this is when the oocyte measures about 0·45 mm. In the highly advanced oocytes there is a well-developed cortex containing the vacuoles. This can be easily separated for demonstration.

The Inheritance of Acquired Characters

PROFS. MACBRIDE and Harrison have devoted some space to refuting a number of statements which I have never made.[1] "He suggested in his discourse that Harrison's strain of sawflies had become contaminated with a strain adapted to the new willow", writes Prof. MacBride. As the discourse is printed in NATURE of June 4 and 11, it is easy to verify the fact that I made no such suggestion. Nor have I ever made any of the criticisms found in Prof. Harrison's last paragraph. I was, however, quite aware of the facts of which he accuses me of lack of knowledge. They would doubtless have been relevant had I made the statement attributed to me above.

Perhaps the somewhat imaginative manner in which Prof. MacBride has dealt with my discourse will make readers of NATURE cautious in accepting his interpretations of the work of Dürken, Metalnikoff, and others.

A Reinterpretation of Relativity

THE theory of relativity is an undeniable achievement in physics and is a logical development of the theory of measurement; but it does not have the significance for the universe which is usually ascribed to it. Real time is *not* fused with space, and *absolute simultaneity does have a definite and definable meaning.*

Physics as a science is concerned with measuring and dating and so getting numerical laws. All this gives knowledge about the external world. But it would be a mistake to project this measurational knowledge into Nature without interpretation. The rejection of absolute simultaneity as meaningless has encouraged most relativists to do this.

My analyses have led me to make a distinction between *chronological time* and *real time*. Chronological time is an affair of dating and measuring in terms of some standard motion. Real time is the fact of change, or eventness. I hold that absolute simultaneity has meaning for real time, while operational simultaneity, which is the kind that relativity stresses,

is bound up with light-signalling. When two bodies are moving with respect to one another, their operational simultaneities are not identical. It follows that length (space) and *t* (chronological time) as numerical quantities always require a reference to the frame from which the measurements are made. It is for this reason that physicists speak of space-time. They mean that length and *t* as quantities are not separable.

I have no criticism to pass upon this so long as measurement is not confused with what is being measured. Measurement gives knowledge about Nature. The philosopher—and I hope the physicist also—needs likewise to think clearly about the structure of Nature. It is here that the question of the real nature of time appears. Is the Astronomer Royal's time—to use Eddington's expression—as basic as supposed ? I take it that physicists like Jeans, Eddington, and Millikan are aware of this problem.

It is my thesis that real time is simply the fact of change or eventness in the universe and is always local. There is no change which runs instantaneously across the universe. The unity of the universe is spatial rather than temporal, and is of the nature of substantial coexistence and continuity. Nevertheless, it is correct to speak of a cosmic time if we simply mean the *class of events* coactual with any given event. In real time, simultaneity is the fact of co-occurrence and is not a kind of cosmic temporal relation. It is in this sense only that the universe moves abreast. Past events are those which have perished and are no longer actual. Future events are those which are not yet actual. *Simultaneous events are just the class of actual events*. This is what the philosopher and the physicist must mean by absolute simultaneity. But the physicist has a job of an empirical sort which the philosopher does not have: that of dating and measuring. The job of the philosopher is essentially that of analysis of categories. For him, real time involves the order of succession and the class of actual events in the universe. He is as much opposed as the modern physicist is to Newtonian conceptions of time.

It follows that the fusion of space and time must not be taken as valid for anything but chronological knowledge about Nature. In Nature itself, only the actual exists. I am also led to believe in determinate size apart from measurement. Quantities are cases of knowledge about and are relative to a frame; but not so the intrinsic properties of things. I am also led to believe in gravitational forces and to distinguish them from the kinematic description in terms of space-time. It follows also that relational movements have meaning as well as relative motion. Relational movements are changes of neighbourhood, while relative motion is an affair of epistemic reference, which presupposes actual movement.

Finally, so far as I can see, cosmic time has no arrow of an entropic sort. It is merely the fact of dispersed change in a substantial, extended world. I expect to find that Millikan, Lewis, and Bridgman will turn out to be right in their criticism of the application of entropy to the universe.

The Absorption Spectrum of Hexuronic Acid

As part of a systematic study [1] of Prof. Szent-Györgyi's 'hexuronic acid' we have investigated quantitatively the absorption spectra of hexuronic acid, glycuronic acid, galacturonic acid, tetramethyl γ-fructose, and other carbohydrate derivatives. In view of the fact that hexuronic acid has been identified with vitamin C,[2] we have paid special attention to the possibility of contamination by small traces of impurity. We find that the single broad band at about 263 mμ reported qualitatively by F. P. Bowden and C. P. Snow [3] is found in equal intensity with the sample of hexuronic acid supplied by Prof. Szent-Györgyi and with rigorously purified material. It appears, therefore, that this band is definitely associated with hexuronic acid. The nature of the band in methyl alcohol (*c.* 0·002 per cent) is indicated by the accompanying table:

Mol. Extinction Coefficient (ε).	Wave-length (mμ).
1000	295
2000	220, 290
3000	228, 285
4000	235, 280
5000	241, 278
6000	245, 272
7000	254, 268
7500	263

Marked deviations from Beer's law were observed, the solutions becoming relatively less transparent on dilution. For example, at 280 mμ the molecular extinction coefficient has the values 800, 2000, and 4400 for solutions of concentration 0·02, 0·005, and 0·002 per cent respectively. Dilute methyl alcoholic solutions of hexuronic acid are unstable and show, when kept, a gradual diminution in the intensity of the band.

In water a single broad band is displayed at 260 mμ. The value of ε is about 7000 for freshly prepared solutions (*c.* 0·002 per cent), but in this solvent a rapid diminution in the intensity takes place, ε falling to 4000 within three hours.

The absorption of hexuronic acid resembles that of many ketonic substances, but differs completely from that shown by aldose or ketose sugars of the pyranose type,[4] which show no absorption bands. We have now proved that a typical keto-furanose sugar (tetramethyl γ-fructose) shows no selective absorption. Similar results were obtained with glycuronic acid and with galacturonic acid. All these substances are highly transparent in water and display weak continuous absorption, with ε in each case less than 5 at 260 mμ.

The tentative formula for 'hexuronic acid' previously suggested [5] envisages a possible keto-furanose sugar structure with the carboxyl group in position 6. In view of the above results, it seems improbable that such a structure would account for the absorption band observed with hexuronic acid, and some rearrangement of the formula may therefore be necessary. Experiments to decide this are now well advanced.

Crystalline Structure of Hexuronic Acid

FROM a purified specimen of 'hexuronic acid' (identified by Szent-Gyorgyi with vitamin C) available in this laboratory I have been able to obtain sufficiently good crystals to carry out an X-ray examination by the single-crystal rotation method. The substance is monoclinic sphenoidal, with $a = 17·71$, $b = 6·32$, $c = 6·38$ A., and $\beta = 102\frac{1}{2}°$, while the space-group is C_2^2 ($P2_1$), since the only true halving is

(0k0) absent when k is odd. The density of the crystals was determined by the flotation method to be 1·65 gm./c.c., so that there are four molecules of $C_6H_8O_6$ in the unit cell. Since C_2^2 has only twofold symmetry, a pair of molecules must be associated to form the asymmetric crystal-unit. (This does not necessarily imply polymerisation.)

On examination microscopically, the crystals are found to be tabular on (100), usually almost square, and exhibiting pronounced cleavage parallel to (010). The birefringence is very high and negative, the refractive indices being $\alpha = 1{\cdot}464$, $\beta = 1{\cdot}68$ (approx.), and $\gamma > 1{\cdot}70$, with α parallel to the b-axis. These results indicate that the molecules are nearly flat and lie in the (010) plane. The birefringence (>0·24) is much higher than any so far observed among the carbohydrates or their derivatives, although that of γ-mannonolactone is about half this amount. This suggests that the hexuronic acid molecule has a ring structure with fewer groups projecting out of the plane of the ring than a normal carbohydrate, and contains double-bonds, possibly in carbonyl groups. The X-ray results are in agreement with these conclusions; the thickness of the molecule must be ½ b, that is, 3·16 A., which is considerably less than that of any carbohydrate so far examined, indicating a flatter molecule, while the regular falling off of the intensities of the {020} reflections also requires a fairly flat molecule parallel to (010).

A very interesting feature of the X-ray results is that unless very long exposures are given, the photographs show no reflections from ($hk0$) planes for which h is odd. This indicates an almost perfect glide-plane of symmetry perpendicular to the c-axis, and therefore a pseudo-plane of symmetry in the molecule itself, at right angles to the plane of the ring. Since carbon and oxygen have nearly the same volumes and scattering powers, such an arrangement can occur without destroying the optical asymmetry of the molecule.

Optical examination and X-ray powder photographs show that the purified hexuronic acid is identical with the crystalline portion of the original substance obtained from Prof. Szent-Gyorgyi. (The amount of impurity in the latter is apparently quite small.)

A more detailed account of this work will be offered for publication in due course. I am indebted to Dr. E. L. Hirst for supplying the purified material and for numerous helpful discussions.

Anaerobic Activation of Glycolysis in Tumour Tissue

ROSENTHAL[1] has shown that when the anaerobic conversion of fructose to lactic acid by the Jensen rat sarcoma is studied by Warburg's method, a spontaneous increase in the rate of acid production ($Q_M^{N_2}$), which he ascribes to the anaerobic formation of an activator, occurs about forty minutes after the manometric vessels are put into the thermostat at 38° C. We have been able to show that this spontaneous increase may also be demonstrated when glucose is the substrate, although here the pre-activation period is shorter; and we find that with both sugars the pre-activation period is abolished when sodium pyruvate is present in 10^{-3} M concentration.

Sodium pyruvate was stated by Mendel, Bauch, and Strelitz[2] to increase the anaerobic fermentation of glucose by normal body tissues. We find that when sodium pyruvate is added, by tipping from a side bulb, to Jensen rat sarcoma in fructose-containing Ringer solution during the period preceding the spontaneous increase of anaerobic fermentation, $Q_M^{N_2}$ rapidly rises and remains constant at approximately the value which would eventually have been reached by the spontaneous activation; whereas after this latter has occurred, addition of sodium pyruvate has no effect (Fig. 1 (i)). Further, the Mill Hill fowl tumour, although attacking fructose with about the same vigour as the Jensen sarcoma, does not show this spontaneous rise in lactic acid formation, and in this case sodium pyruvate shows no action.

A spontaneous increase of rate of lactic acid formation from glucose is not ordinarily observed with the Jensen rat sarcoma. We find, however, that if the tumour slices be suspended anaerobically at 38° C. for

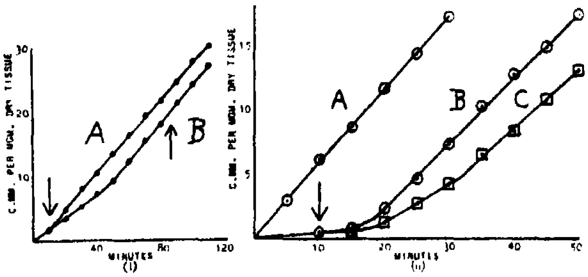

FIG. 1.—Lactic acid production by Jensen rat sarcoma, (i) in 0·2 per cent fructose solution; A, pyruvate added at 10 min.; B, pyruvate added at 85 min. (ii) A, glucose present from start; B, glucose and pyruvate added at 10 min.; C, glucose only added at 10 min.

20 minutes in sugar-free Ringer solution in the manometric vessels and glucose be then added from the side bulb, a preliminary de-activation results which allows a spontaneous re-activation to be observed. For after glucose addition, $Q_M^{N_2}$ does not immediately rise to its final value, but stays at a steady intermediate value for about 15 minutes and then rises rapidly to its steady final level. The presence of 10^{-3} M sodium pyruvate in the solution, or its addition together with the glucose, abolishes this preliminary period, $Q_M^{N_2}$ rising rapidly to the final value very soon after the glucose is added. Addition of 10^{-3} M pyruvate to the solution when glucose is present from the start causes no increase in the anaerobic lactic acid formation (Fig. 1 (ii)).

It thus seems that sodium pyruvate may replace the anaerobic activator in partially activated tissues, but has no effect when the activation is complete. The detailed results will be published in due course.

Anomalous Adsorption on Active Charcoal

AT the recent discussion of the Faraday Society on the "Adsorption of Gases on Solids", Prof. A. J. Allmand and his co-workers[1] presented a summary of their investigations on the discontinuities they have found in adsorption isotherms for gaseous adsorptions.

They also referred to unpublished evidence, obtained by Chaplin, for the discontinuous adsorption of phenol from aqueous solutions on an active technical charcoal. This statement apparently refers to an investigation the details of which have now been published.[2] Of the three isothermals obtained, Chaplin prefers to place reliance upon the third one, the other two being inaccurate for the reasons discussed by the author himself. Chaplin has drawn an isothermal curve through the experimental points which exhibits marked discontinuities. It appears, however, that the curve has been drawn in an arbitrary manner, and a smooth adsorption isotherm can be obtained within the experimental error, only one point being markedly off the curve.

If the existence of discontinuities could be clearly substantiated, then this must lead to a reconsideration of current adsorption theories. With the hope of throwing some light on the subject, it was decided to

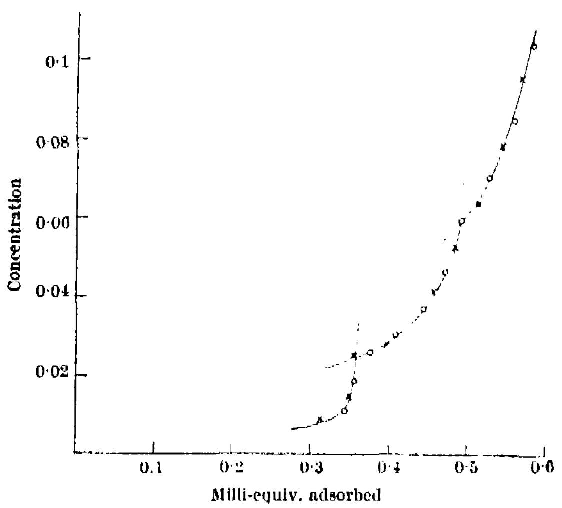

FIG. 1.—Curve showing the quantity of phenol adsorbed (milli-equivalents) from 25 c.c. solution per gm. of charcoal as a function of the concentration (milli-equivalents in 25 c.c.).

repeat Chaplin's work, employing another and probably more accurate method of analysis. The adsorbent used was an oxygen (atmospheric) activated ash-free sugar charcoal which has been employed previously,[3] and the concentrations of the phenolic solutions were determined with a Zeiss interferometer; the phenol used had been purified by repeated fractional distillation. A very unusual adsorption isotherm (25°) was obtained (Fig. 1) with two series of measurements. No discontinuities of the type postulated by Allmand and his co-workers have been found, but the isotherm is composed of three distinct curves, each of which appears to extrapolate back to the origin.

Several interesting possibilities present themselves, but it is desirable to investigate the phenomena more intensively before a detailed discussion is entered upon. It is, however, worth pointing out that each of the curves, when treated independently, conforms to the adsorption theory of Langmuir.

Effect of Carbon Monoxide on the Biological Reduction of Nitrate

THE reduction of nitrate is accomplished by cells of very diverse types—plant, animal, and bacterial. A thermolabile catalyst controls the activation of nitrate, though cases are known where apparently nitrate may be reduced by biological means without the intervention of a specific catalyst.[1] The distribution of the nitrate oxidase, as the catalyst may be conveniently termed, seems to be very haphazard; it occurs in the livers of most animals, but nitrate reduction in muscle is confined to the rat and guinea-pig. Among the bacteria, it is absent from obligate anaerobes and aerobes, but it occurs in most faculative anaerobes. With these organisms nitrate serves as an oxidising source and will enable anaerobic growth to occur in its presence.[2] The nitrate oxidase is present in *B. coli*, the ability of which to reduce nitrate to nitrite has been made a test of its presence in biological fluids. The activity of the enzyme is greatly inhibited by traces of hydrogen cyanide,[3] but if a suspension of *B. coli* which has been exposed to quite a high concentration of hydrogen cyanide is well washed with saline the organism regains its ability to activate nitrate.[4] The effect of cyanide on nitrate oxidase is thus reversible.

Preliminary experiments, carried out recently in this laboratory, now indicate that carbon monoxide has a small but definite inhibitory action on the reduction of nitrate by *B. coli*, the inhibition apparently being greater the smaller the quantity of nitrate present.

Nitrate reduction by *B. coli* in presence of a suitable donator is not only inhibited by carbon monoxide but also by oxygen, the effect with oxygen being far greater than with carbon monoxide. From the facts available so far, it would seem that nitrate, carbon monoxide, and oxygen all compete for the nitrate oxidase, and the inference would be that the enzyme belongs to the iron-containing class of molecule which has been described as responsible for the activity of peroxidase, catalase, and the indophenol oxidase. Further investigation is necessary to decide whether this is the case.

There is some evidence that the chlorate oxidase of *B. coli* is inhibited also by oxygen and carbon monoxide.

Details of this work will be published in due course.

Zoological Nomenclature

IN accordance with prescribed routine, the undersigned invites the attention of zoologists to the fact that application has been made to the International Commission on Zoological Nomenclature to suspend the Rules and to place in the Official List of generic names:

Lepidocyclina Gümbel, 1868, type (1898) *Nummulites mantelli*; objective synonym *Cyclosiphon* Ehrenberg, 1856, type *N. mantelli*; *Lytoceras* Suess, 1865, genotype *Ammonites fimbriatus* Sowerby; and *Ophiceras* Griesbach, 1880, genotype *O. tibeticum* Griesbach.

These cases will be held open until about July 1, 1933, to enable zoologists to submit to the Commission their opinions, for or against the proposition.

C. W. STILES,
Secretary.

Hygienic Laboratory,
Washington, D.C.

Research Items

English Folk-Dances.—Miss Maud Karpeles has published in *Folk-Lore*, vol. 43, No. 2, a study of the survival and revival of folk-dances, in which she reviews the principal types of folk-dance with special reference to the study of their meaning as a borderline province for the folk-dancer and the folk-lorist. The sword dance, which has survived in Yorkshire, Northumberland, and Durham, is danced by five men, or in Yorkshire by six or eight men, usually accompanied by additional characters, the 'fool', the 'king', 'queen', and 'Bessie'. The sword in Yorkshire has a wooden handle at one end but in Durham is a piece of flexible steel with a handle at each end. In the climax of the dance the swords are woven into a 'lock', 'nut', 'rose', or 'glass', and one character suffers a mimic decapitation. There are several features in the dance as it was sometimes performed which point to a play from which it has become detached. Fragments of the play have been noted and, like the mummer's play, it is evidently of a ritual character, a fertility rite of which an animal sacrifice once formed part. The other main type of spectacular dance is the morris, for the name of which the best derivation up to the present seems to be 'Moorish', as referring to the blackened faces of the dancers in earlier times, of which traces survive in a smudge of black worn by some dancers in recent times. The morris may be an offshoot of the sword dance. There is, however, no trace of the sacrificial victim, though there are signs of a sacrificial or sacramental rite which are not embodied in the dance itself. It may be a processional lustration dance in which the stationary dance at certain spots has been elaborated at the expense of the processional.

Ritual Use of Fire in Queensland.—Mr. Donald F. Thomson describes in *Man* for July some ritual uses of fire among the Koka Dai'-yuri and other tribes of the lower Edward River, Gulf of Carpentaria, among whom social life differs little except in detail. As a centre of family life, fire establishes or affirms a bond of solidarity between individuals or within the group. Each family has its own fire, and family life centres around it. Of the two camps consisting of the single men and single women respectively, each has its own fire; and however intimate may be relations, no individual from outside the family joins the family fire; he has his own fire, though it may be only a few yards away. In the Ompela tribe, the simple act of sharing a fire in the presence of the camp constitutes the marriage ceremony. At the critical stages of life when an individual is cut off from participation in normal social activities, he or she camps at a fire apart from others. Fire is presented ceremonially to visitors. On approaching the camp they sit down outside until a 'big' man unarmed has sat down opposite them and then after a period has ordered a small piece of smouldering fire to be brought from the camp and presented to one of them. They then enter the camp. Fire is also used ceremonially in connexion with mourning and burial rites. After the body or bones of the deceased have accompanied the mourners for a period of two or three years, and the time has come to end the mourning, the body is laid in the dry bed of a river and a fire lighted at its head, while food and a small trough of water stand by. After a dance by the women and laments from the men, the mourning paint is washed off and the fire extinguished with the water from the trough, as all lament loudly.

Inheritance of Alkaptonuria.—So early as 1902, it was suggested that alkaptonuria is determined by a recessive Mendelian factor. The condition is apparently due to the absence of an enzyme which catalyses the destruction of homogentisic acid in the human body, with the result that this substance is excreted in the urine. In an analysis of all the accumulated evidence, Messrs. Hogben, Worrall, and Zieve (*Proc. Roy. Soc. Edin.*, **52**, Part III., No. 13) have summarised all the known pedigrees and confirm the above conclusions. The condition is very rare, being estimated to occur less frequently than 1 in 1,000,000 of the population. While it is recessive in a large majority of pedigrees, it occurs as a dominant in certain families, and particularly in one pedigree of four generations. One case of its probable origin by mutation is also recorded. The total number of recorded cases is now 151, of which 100 are males and 46 females. There is at present no satisfactory explanation of the excess of males, but the results are otherwise in accord with Mendelian expectation.

Parasitism and Nutrition in Sheep.—Field trials carried out in 1931 by Dr. I. Clunies Ross and N. P. Graham, of the Division of Animal Health of New South Wales, revealed the predominant influence of good nutrition over parasitism in sheep (*J. Council Sci. Ind. Res.*, vol. 5, 1932, p. 31). Lambs belonging to a lot known to be heavily infected with various internal parasites, the more important of which were the stomach worms, *Hæmonchus contortus*, *Ostertagia circumcincta*, and intestinal worms belonging to the genera *Trichostrongylus* and *Nematodirus*, were divided into five lots and run on different qualities of pasture. All the sheep were weighed at monthly intervals, and fæces from five sheep in each group were cultured each month to determine the type and degree of parasitism. The trial ran from March 26 to Oct. 23–24, when the sheep were finally weighed and shorn. It was found that the increased risk of parasitism due to heavy stocking on improved pasture was more than offset by the improved condition of the sheep run on such pastures. The difference between the produce of un-top-dressed natural pasture and of improved pasture without rotation (at 2½ sheep an acre) amounted to 18 lb. 5 oz. of wool and 83 lb. 7 oz. of live weight per acre, and still further gains were recorded where a monthly rotation was in force. Medicinal treatment against internal parasites produced no demonstrable effects in treated sheep in comparison with untreated sheep under the same conditions on improved pasture. Indeed, at the end of the trial, practically all worm infestation appeared to have been thrown off by sheep on improved pastures, whether the animals had been treated or untreated.

Mammal Coloration Simulating Environment.—In 1929, L. R. Dice described two pocket mice and a wood rat from New Mexico, the colours of which strikingly matched those of their rather peculiar and distinctive surroundings. A further study of the distribution of these forms, carried out by Seth B. Benson and two colleagues in the Tularosa Basin and the neighbourhood, has discovered three more rodents which tend to match the colour of the lava fields on which they live and to which they appear to be restricted. These new subspecies, which have been named *Citellus grammurus tularosæ*, *Perognathus intermedius rupestris*, and *Peromyscus nasutus griseus*, have not reached the degree of blackness of the lava-dwelling wood rat and pocket mouse, but appear to be intermediate stages between the ordinary colour and the black stage. They are described, with two plates, by Benson (*Univ. California Pub. Zool.*, vol. 38, 1932, p. 335).

Irish Euphausians.—Miss Winifred E. Frost in her work on the reproduction of *Nyctiphanes couchii* and *Meganyctiphanes norvegica* from off the south coast of Ireland (*Proc. Roy. Irish Acad.*, vol. 40, Sec. B, No. 14, 1931) investigates the breeding seasons of these euphausians and finds the larvæ of *Nyctiphanes* throughout the year with an April maximum. It probably has a spring and an autumn brood, whilst *Meganyctiphanes* apparently breeds in spring and summer with only one brood. As both these species, including the larvæ, form a large part of the food of herring, mackerel, and young hake, a detailed knowledge of their life histories is very important, and Miss Frost's observations give us some valuable information concerning the seasonal distribution of the larvæ. The area investigated lies off the south coast of Ireland and extends for about one hundred and fifty miles north and south, and for approximately two hundred miles from east to west, including both inshore and offshore waters. The main material consists of vertical plankton hauls taken with a Nansen net of two types, supplemented with occasional hauls with the Petersen trawl. It represents 31 cruises, spread over eleven years (1920–31). The distribution of the two species appears to be similar, although in the English Channel *Nyctiphanes* is usually found much nearer the coast than *Meganyctiphanes*. Both larvæ and adults occurred at one of the Irish stations with a depth of 150 metres. These two, both larvæ and adult, are the most frequent species in the plankton of the waters less than 100 fathoms deep off the south coast of Ireland, the distribution of the larvæ being 'patchy' without regard to depth or to a salinity range of 34·8-35·5 per mille. Only very general observations were made on vertical distribution, but the author found that the bulk of the calyptopis stages of *Nyctiphanes* are in the upper waters both day and night, whilst the older larvæ and adults were more abundant in the upper waters at night, which agrees with similar observations at Plymouth.

Fossil Marsupial from Africa.—Prof. E. Stromer, of Munich, has just described the first fragments of a fossil marsupial mammal from Africa (*Sitzungsb. Bayer. Akad. Wiss., math.-naturw. Abt.*, 1931 [1932], p. 177). They are portions of a lower jaw from a Middle Pliocene river-deposit south of Port Nolloth, Little Namaqualand, South Africa, and belong to an animal about as large as an ordinary rat. The dentition is sufficiently well preserved to show that the newly discovered species must have been closely related to the diprotodont marsupial *Cœnolestes*, which now lives in South America, and is represented by several extinct allies in the Tertiary rocks of Patagonia. The African form is generically distinct, and is named *Palæothentoides* by Prof. Stromer, who remarks on the interesting geographical distribution of the cænolestid group of marsupials which is thus extended.

Wood Anatomy in Mangrove Swamps.—Alexis J. Panshin has studied the Philippine mangrove swamps from a new point of view (*Phil. J. Sci.*, vol. 48, No. 2, June 1932). The trees found in these forests belong to very different families, but are all growing in a remarkably uniform and very characteristic habitat. Panshin, therefore, studied the anatomy of these woods to see whether their common structural feature suggested a direct connexion between habitat and anatomy. All of the woods were typically diffuse-porous and the vessels had usually comparatively small diameter. Apart from these two features, great diversity of structure was represented amongst the large number of species examined, and the author concludes, in agreement with Solereder, that habitat does not impress any definite type of anatomical structure upon species with a different evolutionary history.

Hypal Fusions in Dermatophytes.—Prof. A. H. R. Buller and his colleagues have devoted much attention to the study of hyphal fusions in various fungi. They have now turned their attention to a practical application of this knowledge ("Hyphal Fusions in Dermatophytes", by A. M. Davidson, Eleanor S. Dowding, and A. H. R. Buller, *Canadian Journal of Research*, vol. 6, No. 1, pp. 1-23, 1932). Studies on species of *Microsporon* and *Trichophyton*, which cause sores upon the skin and hair of human beings, have been made. It was found that hyphal fusions formed between any two mycelia of the same species isolated from different patients, but did not form between the hyphae of two different species. A simple method of hanging-drop culture was used to compare the behaviour of an undetermined fungus with that of a stock culture. This method gave a trustworthy criterion for the identification of species, and may prove of great use in the treatment of human skin diseases.

Earthquake Frequency at Kilauea.—The *Volcano Letter* for Feb. 4, issued at the Hawaiian Volcano Observatory, contains a remarkable curve representing the seismicity of Kilauea during the past four years. In estimating seismicity, shocks of intensities 1, 2, and 3 of the Rossi-Forel scale are given the weights 1, 2, and 3, very feeble shocks the weight ½, and tremors that scarcely show on the seismograph records the weight ¼. The number of tremors are occasionally very great, for example, 6531 and 10,080 during the weeks ending last Dec. 28 and Jan. 4, and, to keep the curve within reasonable limits, the logarithms of the weekly figures of seismicity are used. The outstanding features of the curve are the high peaks of suddenly increased activity that accompanied the four outbreaks of Halemaumau on Feb. 28 and July 25, 1929, Nov. 19, 1930, and Dec. 23, 1931, eruptions that were progressively more intense and lasting. The small oscillations tend to recur at intervals of from two to six weeks, with an average of 3·4 weeks.

The Granular Theory of Matter.—Volume 75 of *Memoirs and Proceedings of the Manchester Literary and Philosophical Society* contains the Dalton Lecture delivered before the Society by Sir J. J. Thomson on the occasion of his receipt of the Dalton Medal of the Society for his "eminent services to science", on March 17, 1931. The lecture was entitled "Atoms and Electrons", and in it Sir Joseph showed how the discovery that an electron moving with velocity u is always accompanied by waves of length equal to the quotient of Planck's constant h by the momentum mu of the electron, and of frequency proportional to the energy of the electron, had led him to the theory that matter was composed of granules of mass μ, less than 3×10^{-37} gm., all moving with the speed of light, the force on any granule being always at right angles to its path and producing therefore no change in the energy of the granule. When lines of electric force connecting protons and electrons link these granules together, the combination constitutes matter, and the mass of the proton or electron is the sum of the masses of the granules gripped by its lines of force, and the energy the sum of their energies. Further, if each granule is exposed to a succession of impulses ν_0 per second, the time of the impulses for each granule being arbitrary, for a mass m having m/μ granules the frequency ν of the disturbances will approximate closely to $\nu_0 m/\mu$ and the energy of the mass to $\nu\mu c^2/\nu_0$, which if we write h for $\mu c^2/\nu_0$ gives Planck's law.

Liquid Helium.—Prof. J. C. McLennan and some collaborators have published in the June number of the *Philosophical Magazine* some interesting photographs of liquid helium. The liquid was very quiet, and had a meniscus with an almost negligible curvature at the edge and scattered very little light. Examined for Raman spectra, it was found to exhibit no isolated modified lines; the intensity of any possible Raman line was certainly fainter than the weakest Raman line observed in the spectrum of the light scattered from liquid oxygen or liquid nitrogen. The unmodified lines were, however, accompanied by very faint wings, probably to be attributed to rotational changes in unstable helium molecules in the liquid, of a structure recently investigated by Weizel, and formed from a pair of helium atoms each in the normal $1S$ state. This work was done with the low temperature form of the liquid, the form boiling above about 38 mm. pressure being continually full of bubbles which caused large spurious scattering.

Excitation of the Nebular Spectrum.—A short note by H. Nagaoka and T. Futagami (*Proc. Imp. Acad. Japan*, March) contains the announcement of the production in the laboratory of a fresh part of the nebular spectrum. An arc was run between carbon poles in nitrogen or oxygen which had been partly dissociated and ionised previously by causing it to pass through a hole in the carbon. The arc was spread out sideways by a magnetic field, and an auxiliary condensed discharge passed through it, between silver electrodes, at a distance of 15 cm. from the axis of the main poles. The luminosity of the auxiliary discharge extended somewhat towards the carbons, but the more remote parts were free from the bands of carbon monoxide and nitrogen, and showed only silver lines and lines of ionised oxygen and nitrogen. It is stated that the latter included many found in nebulæ and ascribed by Bowen to singly charged oxygen and nitrogen (O II and N II) and to doubly charged nitrogen (N III). The lines coming from doubly charged oxygen (O III) were not observed.

Structure of Tetramminoplatinous Chloride.—Werner's view that the 4-co-ordinated compounds of bivalent platinum possess a planar configuration, the four groups occupying the corners of a square with the platinum at the centre, has been several times contested. Pauling has, however, shown theoretically that the bivalent transitional elements nickel, palladium and platinum can form such compounds with a planar configuration, and, apart from available evidence of a purely chemical nature, his conclusions are supported by investigations on the nickel derivatives of benzylmethyl glyoxime and the X-ray analysis of K_2PdCl_4 and K_2PtCl_4, in which the metal occurs in the anion. Cox (*J. Chem. Soc.*, June) has now shown by X-ray analysis that the same configuration also occurs in the cation, $Pt(NH_3)_4$, of the salt $Pt(NH_3)_4Cl_2, H_2O$, and it appears fairly certain that the bonds to any four identical groups co-ordinated to a platinum atom lie in a plane. The compound in question forms an ionic lattice with one molecule in the unit cell, and the symmetry requires that the ammonia groups are rotating about the covalent bond. The water molecules are loosely held and can be expelled without disrupting the crystal: the best position is probably with the oxygen atom at the centre of the cell. Each platinum atom is surrounded by four ammonia groups in a square and at a greater distance by eight equidistant chlorine ions. Each ammonia group is at the centre of four coplanar chlorine ions, while each chlorine ion is surrounded by eight ammonias.

Astronomical Topics

Comets.—Dr. A. Dubiago gives a definitive orbit for Brooks's periodic comet at its last return, and a predicted one for this year, in *Astr. Nach.* 5874:

T	1925 Nov. 1·729463 U.T.		1932 Oct. 7·5519 U.T.	
ω	195° 30′ 57·33″	1925·0	195° 48′ 18″	1932·0
Ω	177 25 11·60		177 27 11	
i	5 33 11·07		5 32 52	
ϕ	29 8 36·20		29 4 7	
n	513·27574″		511·654″	
log a	0·5597706		0·56075	

An ephemeris from June 5 to Dec. 30 is given; it is very close to that of Mr. F. R. Cripps in the B.A.A. Handbook; Mr. Cripps applied perturbations by Jupiter and Saturn (Dubiago applied those of Jupiter only), and obtained T Oct. 7·623, differing from the other by less than two hours. The conditions this year are very favourable, the comet being in opposition at its perihelion.

The *Journal des Observateurs* for May contains a study by Dr. A. Schaumasse of the periodic comet Borrelly, which has been seen at each return since its discovery in 1905; he has applied perturbations by Venus, Earth, Mars, Jupiter, Saturn, and finds the elements;

T	1925 Oct. 7·53664 U.T.		1932 Aug. 27·79623 U.T.	
ω	352° 25′ 34·11″	1930·0	352° 33′ 6·74″	1930·0
Ω	77 6 12·17		77 2 3·63	
i	30 30 39·83		30 31 47·18	
ϕ	38 3 26·35		38 4 59·78	
n	515·33164″		516·11281″	
Period	6·885251 y.		6·874830 y.	

T in 1932 is 1·8 days later than the value used in the ephemeris in the B.A.A. Handbook. The comet will be well placed as a morning object for northern observers in September and October; a misprint in the Handbook should be corrected. Read 352°, not 325°, for ω.

Slopes of the Lunar Mountains.—Mr. T. L. MacDonald has been contributing a series of papers on lunar statistics to the *B.A.A. Journal*; the issue for May contains a study of the slopes of mountains, which is based on examination of the shadows at different altitudes of the sun. The mean value of the inclination is deduced as being slightly less than 30° for the larger craters, but attaining 36° for those with diameters less than 40 km. Mr. MacDonald states that 30° is the angle at which equilibrium of loose debris is possible. In view of the disturbing effect of the great range of temperature between day and night, the older formations would probably have had time to reach equilibrium; but it is suggested that the small formations may have been the latest, and that there has not yet been time to reach a state of equilibrium. Many of the objects in question are near the borders of the maria, which are likely to be areas of weakness where disturbances may have continued to a later period than in more stable regions.

Mr. MacDonald's work shows that observers need not consider that the moon's surface is so well known that nothing more remains to be done. Visual work can give more continuous records of the changing aspects of the shadows than can be done by photography, in view of the great number of plates that the latter would require.

University Statistics *

THE comparative statistics recently issued by the University Grants Committee for the academic year 1930–31 relate to the twelve universities of England and Wales with their colleges, the independent university colleges of Exeter, Nottingham, and Southampton, the Manchester College of Technology, the four Scottish universities, and the Royal Technical College, Glasgow. The tabular statements, which compress into twenty pages a vast amount of information regarding the finances, students, staffs, and libraries of these institutions, are preceded by an introductory note directing attention to a number of figures of special significance.

Of the 47,587 full-time students included in the returns, 33,569 were in England, 2868 in Wales, and 11,150 in Scotland. Of those in England, nearly a third were at Oxford (4658) and Cambridge (5599), a third at London, and rather more than a third at provincial universities and colleges. One of the tables, entitled "Home and University Residence of Full-time Students", affords a factual basis for criticising certain theories put forward in a recent discussion in the *Universities Review* of the question "What is wrong with the Modern Universities?" It has been suggested that they fall short of what has been expected of them through being too intensely local and through being, in the main, non-residential. The table shows that Bristol and Reading universities and Exeter, Southampton, Aberystwyth, and Bangor university colleges draw more than half of the total number of their full-time students from homes more than thirty miles distant, and can therefore scarcely be described as predominantly 'local'. It shows, too, that Reading, Exeter, and Southampton accommodate more than half their full-time students in colleges or hostels, and may therefore fairly claim to be considered 'residential'. Excluding London, where the proportion of students so accommodated is small, 52 per cent of the full-time women students and 36 per cent of the men were in colleges or hostels.

The same table shows also how many of the full-time students came from homes outside the British Isles but within the British Empire (2759) and how many were from foreign countries (1809). The percentage of foreign students has increased in recent years.

As regards the character of the work in which university students were engaged, they are graded in Table 3 as 'advanced' (including research workers), 'first degree', and 'diploma'. Full-time students were distributed among these grades as follows: 2237; 36,886; 8464. The table includes also particulars of 14,725 part-time students, of whom 8280 were not classifiable under the above grades, as the courses they followed did not lead to degrees or diplomas: more than half of these were in London (chiefly University and King's Colleges and the London School of Economics) and Glasgow (Royal Technical College). A further indication of the standard of work is afforded by the number of higher degrees (excluding those granted without examination), namely, 1323, and higher diplomas, 346.

Fields of study are demarcated in five compartments: arts (including theology, fine art, law, music, commerce, economics, and education), pure science and mathematics, medicine (including dentistry), technology (including engineering, applied chemistry, mining, metallurgy, architecture, etc.), and agriculture. The distribution of the general body of full-time students was: arts 51·8 per cent, medicine 20·8, pure science 16·5, technology 9, agriculture 1·9; but taking advanced students alone, the pure science group is the largest (42·6 per cent), followed by arts (38·4), medicine (7·6), technology (9·7), and agriculture (1·7). The following table gives the names of the universities in which the pure and applied science groups (excluding medicine) were most numerous:

Pure Science.		Technology.		Agriculture.	
Cambridge	1168	London:		Reading	190
Oxford	569	Imp. Coll.	602	Cambridge	157
Manchester	530	Univ. Coll.	265	Edinburgh	133
London:		Cambridge	568	Oxford	99
Univ. Coll.	518	Liverpool	326	Aberdeen	74
Imp. Coll.	376	Glasgow	304	Aberystwyth	58
Glasgow	429	Manchester:			
Liverpool	295	Coll. of Tech.	272		

Of the advanced work in pure science, four-fifths was in chemistry and physics.

The financial statements show incomes amounting in the aggregate to nearly six million pounds, as follows:

London	£1,607,140
Oxford and Cambridge	1,053,477
English Provincial Universities and Colleges	1,960,153
Wales	346,768
Scotland	863,389

These figures include the addition to the Treasury grant voted by Parliament in 1930 for the quinquennium beginning 1930–31, and show therefore a considerable advance upon the figures for the previous year. Parliamentary grants, together with grants from local authorities, now constitute on an average 45 per cent of income in England, 67 per cent in Wales, and 43 per cent in Scotland. Thanks to the addition to the grant, only ten of the fifty-two institutions ended the year with deficits, and the aggregate amount of these was but £11,403.

Expenditure on libraries, which is exhibited in some detail in a special table, amounted to four per cent of the total expenditure, and more than ten per cent of it was for purchase of learned journals. Commenting on this, the committee observes that "the most serious and perplexing problems which at present exercise the minds of librarians all the world over are those which arise out of the increasing number and cost of periodicals".

Condensed and Dried Milk *

DR. L. A. ALLEN, of the recently founded Hannah Dairy Research Institute, has brought together and reviewed, in the publication before us, the facts relating to the preparation of condensed and dried milk products. The pamphlet appears at an opportune time, since for reasons of national economy efforts are now being made in Great Britain to increase supplies of home-produced foods. Large amounts of condensed and dried milk are imported annually into the country, the totals for 1931 being given as 2,700,000 cwt. and 250,000 cwt. respectively.

Just as in the case of the commercial canning of

* The Hannah Dairy Research Institute. Bulletin No. 3: The Properties of Milk in relation to the Condensing and Drying of Whole Milk, Separated Milk, and Whey; a Review of existing Knowledge. By Dr. L. A. Allen. Pp. 159. (Auchincruive: Hannah Dairy Research Institute, 1932.) 4*s*. 6*d*. net.

fruit and vegetables, where at the present time, by improvements in technical methods and the organisation of suitable supplies, an important industry is developing, so in the condensation of milk—whether to furnish evaporated (unsweetened) milk, sweetened condensed milk, or dried milk—development ought not to be difficult. The first requisite for such development is a knowledge of the raw material, and in Part 1 of the bulletin an account is given of the influence of the various components of milk in condensing and drying. Part 2 deals with the colloidal properties of milk, as these are important with reference to coagulation by heat in the manufacturing processes, and in the alcohol test, by which the suitability of milk for condensing is judged. The influence of heat on milk, both as regards the bacterial flora and changes of a chemical nature, are discussed in Part 3, and the effect in both cases is shown to have important bearings upon factory methods and upon the final product.

The manufacture of sweetened condensed milk is, as would be expected, described fully, the technical operations first being outlined. Sections on the bacteriology of the product, the control and testing of the raw milk, the bacterial flora of milk, all give a good résumé of the present state of knowledge. In the last section of Part 4 are described the defects in condensed milk, due on one hand to micro-organisms and on the other to chemical or physical changes.

In Part 5 evaporated milk is dealt with in a similar manner, and in Part 6 dried milk; in the latter Part the composition and properties of milk powders are discussed especially with reference to keeping qualities.

The waste of valuable food material in the whey from cheese factories—the loss has been estimated to be about £1,000,000 annually in Great Britain—has occasioned much thought, and a certain amount of research work has been undertaken, but so far no commercially successful method of utilising the whey has been put into operation. What has been achieved is recorded in Part 7, and it seems very probable that with the knowledge now available and the perfecting of the engineering details a food capable of being used in the confectionery and sweet trades will be manufactured economically.

The final part of the bulletin discusses the uses of condensed milk and dried milk in the household and in industry.

The writer of the bulletin—Dr. L. A. Allen—is to be congratulated upon the thoroughness with which he has gathered together the material, and upon the skilled and critical manner in which he reviews it. In each section the points having a bearing upon the subject under discussion are clearly brought forward.

Altruism in Science and Industry

UNDER the title "Science and Industrial Sanity", in the *Hibbert Journal* for July 1932, Mr. H. P. Vowles and his late wife, Margaret Vowles, discuss some of the effects of the application of science to industry during the last century and half, particularly the enormous increase in productivity and the unaccompanying unemployment. They reject at the outset the pleas for a return to the pre-scientific age or for the suspension of scientific research and its application to industry for several decades, and point out that the spectacular increase in productive capacity has been accompanied by a considerable change in the ethical standards of industry. Wherever science has influenced industrial activity, the spirit of service has come into competition with the desire for private gain. The serious problems with which mankind is now confronted are mainly attributed to the existence of whole tracts of industry, notably those concerned with the monetary aspects of distribution, which are uninfluenced by science, and where alike the scientific method and the spirit of service have yet to penetrate.

In support of their contention, the authors refer to the noble tradition of science that the service of mankind should be given precedence over personal advancement, and to the part played by the engineer in the permeation of industrial activities with the ideal of public service. Engineering institutions and societies have all adopted the attitude that though engineers must normally earn a living by their work, the primary purpose of engineering activity is the service of mankind. Political economy similarly became imbued with the idea that co-operation is a nobler ideal than self-interest, and to-day the idealism of the engineering societies is only one of the indications that as industry becomes more influenced by science the obligation upon all to subordinate self-seeking to the common good becomes more widely acknowledged.

Accordingly, with this change in mind, it is possible to view without dismay the enormous increase in the power resources affecting not only manual but also clerical labour, or the realisation that the mechanical invasion of mankind is only in its initial stages. The penetration of science to the world's monetary and distributive systems is bound to follow; and beyond this, the complete permeation of industry by science, involving the attainment of higher educational levels for all and producing a saner work-day environment, should be of considerable assistance in guiding men to sane uses of the leisure which will be available for all in the completely scientific State. Such rationalisation and reorganisation necessarily involve a very wide margin of leisure for all, but if science enables men to see industry in its right perspective and themselves in their right relation to industry and to one another, the fear that leisure will be used unwisely in the scientific State may never be justified in the event. Nor need we dismiss as utopian the suggestion that science and machinery, and the leisure they make possible, are destined to play an indispensable part in lifting men to new and higher levels of endeavour and achievement.

Development of the 'Grid' in Great Britain

AN address by Sir Archibald Page, chief engineer of the Central Electricity Board, on the 'grid' for electric supply in Great Britain was given recently to the Electrical Association for Women (the *Electrical Age*, July). Sir Archibald points out that there are three main stages of getting electricity to the consumers' terminals, namely, generation, transmission, and distribution. The Central Electricity Board is primarily concerned with the first and in a less degree with the second of these stages.

At the beginning of this century, engineers recognised that electricity can be produced much more cheaply in large quantities, and that electricity is the most convenient agency for the transmission of power, heat, and light. Companies possessing several stations found it advantageous to link them together. The outbreak of the War and the subsequent increased demand for power led to the appointment of the Electricity Commission to regulate and promote the production and distribution of electricity in accordance with modern ideas.

In 1925 the Weir Committee recommended the

establishment of a system of main transmission lines called the 'Grid Iron' for the purpose of interconnecting the principal generating stations of Great Britain, and in due course proposed the shutting down of less efficient stations. To effect this, a new organisation called the Central Electricity Board was set up to manage what may be called the 'wholesale' side of the supply industry. This Board is now hard at work accelerating the completion of the 4000 miles of transmission line and the numerous transforming and switching stations involved, and is already well ahead of its original programme.

Although on technical and financial grounds it was advisable to use overhead lines, it was necessary to use a considerable mileage of cable, mainly in the London district. The value of the orders given by the Board to British firms now exceeds 22 million pounds. This has reacted on unemployment figures and the electrical industry is one of the few flourishing industries in the country. The Board is in no sense a government department. It is part of the supply industry and is financially self-supporting.

Great Britain with its dense population, diversified industries, cheap coal, and extensive coast-line is an ideal country to electrify. What is needed is an efficient organisation to ensure that expansion of output which will bring cheap electricity to the consumer. The field is wide. Only about 65 per cent of the machinery utilised in industry is electrically driven. There are eleven million potential consumers in Great Britain and only about four and a quarter million are connected with the supply mains.

Sir Archibald Page pointed out that Great Britain was the first country to lay down a national system of electric trunk mains. It was now almost impossible to make a train or car journey of any distance without seeing some of the lattice steel towers supporting the electrical conductors which constitute the 'grid'.

University and Educational Intelligence

CAMBRIDGE.—At Emmanuel College the studentship offered for competition to graduates of other universities intending to commence residence as research students in October has been awarded to L. Belchetz, Rhodes University College, Grahamstown, South Africa (chemistry). The studentship held by J. W. Harding (Victoria University College, Wellington, New Zealand) for mathematical physics has been renewed for a third year. Internal studentships offered for competition to members of the college have been awarded as follows: B. V. Bowden (physics) for one year, A. J. Ward (mathematics) for two years.

LONDON.—The following degrees have been conferred: D.Sc. in biochemistry on Manayath Damodaran (Imperial College—Royal College of Science) for a thesis on "The Amino-Acids of Gluterin" (*Biochem. J.*, 1931), "The Dicarboxylic Acid Nitrogen of Proteins" (*Biochem. J.*, 1931), and "The Isolation of Asparagine from an Enzyme Digest of Edestin" (*Biochem. J.*, 1932). D.Sc. in chemistry on Ranchhodji Dajibhai Desai (Imperial College—Royal College of Science) for a thesis entitled "The Influence of Methylcyclopentane and Methylcyclohexane Rings on Carbon Tetrahedral Angle" (*J. Chem. Soc.*, May 1931 and April 1932). D.Sc. in mining geology on Mr. G. C. A. Jackson (Imperial College—Royal School of Mines) for a thesis entitled "The Geology and Ore-deposits of the N'Changa Mine and District, Northern Rhodesia", a portion of which, entitled "The Ores of the N'Changa Mine and Extensions, Northern Rhodesia", has been published in *Economic Geology*, vol. 27, No. 3, 1932. D.Sc. in psychology on Mr. S. J. F. Philpott (University College) for a thesis entitled "Fluctuations in Human Output" (*Brit. J. Psych.*, 1932).

IT is announced that the Prudential Assurance Company has offered to contribute £1500 a year for a term of seven years to the London School of Hygiene and Tropical Medicine. The suggestion that the contribution shall be directly associated for the duration of the gift with the University chair of public health has been accepted by the governors of the School.

THE Science Scholarships Committee of the Royal Commission for the Exhibition of 1851 has made the following appointments to Overseas Scholarships for 1932:—On the recommendation of McGill University: Mr. J. F. Heard (physics, Imperial College of Science and Technology, London), Mr. M. K. McPhail (biochemistry, National Institute for Medical Research, London); on the recommendation of Queen's University, Kingston: Mr. W. J. Henderson (physics, University of Cambridge), Mr. G. S. Farnham (metallurgy, University of Manchester); on the recommendation of the University of Melbourne: Mr. A. B. Edwards (geology, Imperial College of Science and Technology, London); on the recommendation of the University of Sydney: Thelma M. Reynolds (organic chemistry, University of Oxford); on the recommendation of the Universities of Cape Town and the Witwatersrand: Dr. E. C. Halliday (physics, University of Cambridge and the Experimental Station of the Radio Research Board, Slough); on the recommendation of the University of New Zealand: Mr. R. M. Barrer (physical chemistry, University of Cambridge).

Calendar of Geographical Exploration

Aug. 10, 1537.—De Vaca and the Gulf of Mexico

In 1528, Cabez de Vaca had accompanied Pamfilo de Navarez on an expedition which landed on the west coast of Florida near Tampa Bay. In a subsequent march they lost touch with their ships and the party broke up. In the winter of 1528–29, of a party of 80 on the 'Island of Misfortune' off the coast of Texas, only 15 survived. De Vaca was one; he crossed to the mainland and spent five years among the natives. Then, with a companion, he travelled south, crossing the Brazos and Colorado Rivers and reaching San Antonio Bay. Ultimately he reached Mexico City and returned to Europe, arriving at Lisbon on Aug. 10, 1537. His account of the riches of the region which he had visited resulted in the journeys of Coronado and de Soto.

Aug. 11, 1901.—Kaiser Wilhelm II. Land

Prof. von Drygalski left Kiel on Aug. 11 in the *Gauss*, reaching Kerguelen Island on Dec. 31, where a party of German scientific workers had landed a few months earlier and had set up an observatory. The *Gauss* wintered in the ice, and a sledging party discovered the land named Kaiser Wilhelm II. Land, with a hill 1500 ft. high, which was named the Gaussberg. The expedition not only discovered new land, but also recorded many valuable scientific observations.

Aug. 12, 1767.—Carteret's Discoveries in the Pacific

Capt. Carteret in the *Swallow*, after discovering Pitcairn Island, reached the Santa Cruz group. Although these islands had been discovered by Mendaña a century before, their position was but imperfectly known and Carteret may be credited with their rediscovery. Later the group now known as the Carteret

Islands was discovered, though Carteret himself identified them wrongly. Carteret's most important discovery was that the strait between New Britain and New Ireland was a channel and not a bay, as Dampier had concluded. Other small islands were discovered and the south coast of Mindanao was examined, the *Swallow* returning home in 1769.

Aug. 13, 1829.—The North Magnetic Pole

Sir John Ross in the *Victory*, accompanied by his nephew, James Clark Ross, in a ship fitted up by Sir Felix Booth, reached Fury Beach, where Parry had abandoned the *Fury* in 1825. Their object was to find the north-west passage. In this they failed, but the land called Boothia in honour of Sir Felix Booth was discovered, and James Clark Ross, by means of sledge journeys, located the north magnetic pole in 70° 5′ 17″ N., 95° 46′ 53″ W., on the western coast of Boothia. He also discovered and named King William Land and surveyed its northern shore. Their boat was frozen in during its first winter and the Rosses were unable to extricate it. They thus spent four winters in the region, when fortunately they were picked up by a whaling vessel in Lancaster Sound, which they had reached by boat. This whaler, the *Isabella*, was the same ship in which J. C. Ross made his first voyage to the arctic regions in 1818. J. C. Ross in 1839–43 did magnificent work in the antarctic. (See Calendar for Jan. 1.)

Societies and Academies.

DUBLIN

Royal Dublin Society, May 24.—Irish Radium Committee Report for the year 1931. 16,756 millicuries of radon were issued during the year for therapeutic purposes. Detailed reports from some of the largest users record the results of the treatment of 400 cases.—**J. Stuart Thomson**: The anatomy of the tortoise. A study of the morphology of the closely allied species, *Testudo ibera* and *T. græca*, system by system, in a way never attempted in a chelonian since the classic work of Bojanus on *Emys europæ* in 1819. The dissections of the vascular system from injected specimens, showing the complicated connexions of the arteries and veins related to the carapace, are some of the important features. Transverse sections of a six-weeks-old *Testudo* cut in celloidin are figured. The author recommends the importance of some dissections from the dorsal surface, after dissolving away the carapace with acid.—**W. E. Abraham**: Contact angles in an oil-water interface and their application to free flotation in the Weva inclinometer. In this instrument a floating magnet is used to determine the magnetic meridian. The magnet is encased in ebonite coated with gutta-percha, which lies in an oil-water surface in a containing glass vessel. As the water does not wet the gutta-percha, capillary repulsion ensures free rotation.—**J. Lyons** and **G. T. Pyne**: Factors affecting the body or viscosity of cream and relative matters. Data are presented to show the effect of separation temperature, previous chilling, and pasteurisation of milk, and re-separation of chilled pasteurised cream on the viscosity of the ultimate product.

EDINBURGH

Royal Society, June 20.—**Pierre Rijlant**: Automatism and conduction in the mammalian heart. The contraction of the heart starts in the sinus region. This initial activity is accompanied by mechanical and electrical changes limited to the sinus. The cathode ray oscillographic records of the pacemaker's activity show a series of electric waves, each of them being localised to a limited region of the sinus. The initial wave appears in a limited spot situated at the venous side of the sinus and corresponding to the embryological remnant of the right duct of Cuvier. The transmission of this initial activity to the auricle occurs through a differentiated contractile conduction system. In the mammalian heart automatism and rhythmicity occur in a limited region with characteristic structure. These regions are contractile and their contraction is independent from that of the myocardium. Transmission occurs through a differentiated system which unites the different segments of the myocardium.—**L. Hogben**: Filial and fraternal correlations in sex-linked inheritance. When inheritance is sex-linked, the correlations of relatives differ from those based on the more typical mode of transmission, and differ according to the sex of the pairs. As compared with filial correlations of the Pearsonian type, the correlation for father and son is zero, for mother-daughter it remains unchanged, and for father-daughter or mother-son it is raised. The correlation for brother-sister is lowered as compared with Pearson's fraternal coefficient. For brother-brother it remains unchanged and for sister-sister it is raised. From the formulæ given it is seen that no comparison between twin correlation is valid unless the sex composition of the groups compared is identical. In addition, it is seen that a study of correlation between relatives classified in every possible way with respect to sex could provide a means of estimating the contribution of sex-linked genes to the observed variants in a population.—**A. Graham**: On the structure and function of the alimentary canal of the limpet. In *Patella vulgata* the radula, lubricated by the salivary secretion, scrapes the food particles, mainly diatoms and small algæ, off the rocks on which the animal is living, and conveys them to a ciliated food channel running down the fore-gut. Into this channel ciliary currents convey an amylolytic enzyme secreted by side folds in the same region. The mixture of food and enzyme is absorbed by absorbing cells in the digestive gland. The rest of the alimentary canal, of which five histologically different portions may be distinguished, is chiefly concerned with elaborating the waste matter into rod-shaped fæcal masses.—**S. M. K. Henderson**: Notes on Lower Old Red Sandstone plants from Callander, Perthshire. South of Callander, plant-bearing flagstones occupy the centre of a great syncline, and are exposed in the area between the Rivers Teith and Forth. The following have been obtained from an exposure in the Tarr Burn at Ballanucater Farm: (1) *Pachytheca* sp.; (2) *Arthrostigma gracile*, Dawson; (3) *Psilophyton*, Dawson, and associated remains that may belong to the one plant. Those included under (3) may be grouped into (*a*) spiny stems, (*b*) slender spineless dichotomous branch-systems, (*c*) stout and slender branch-systems with axillary structures. The consideration of these remains has raised two questions: Does the association of plants of type (*b*) with those of type (*a*) indicate the appearance of *Hostimella*-like plants in the Lower Old Red Sandstone, or may they be classed under some such form as *Psilophyton goldschmidti*? The second question concerns the demonstration of axillary structures in some of the branch-systems (*c*). Do they belong to spiny axes of *Psilophyton* type, or do they indicate the presence of another type that would have to be classed as *Hostimella* sp.?

PARIS

Academy of Sciences, June 20 (vol. 194, pp. 2181–2248).—**H. Douvillé**: Notice on the work of Albert de Grossouvre.—**C. Matignon** and **M. Léon**: The thermo-

chemistry of the calcium orthophosphates.—**Louis Blaringhem**: The inheritance of sex in meadow sage (*Salvia pratensis*). Although the author has been unable to establish a line of *S. pratensis* containing only female descendants, it is probable that in six generations the percentage of individuals of this sex could be raised to 90 per cent.—Jean Tilho was elected a member of the Section of Geography and Navigation in succession to the late General Ferrié. Jean Cabannes was elected *correspondant* for the Section of Physics.—**Jean Bosler**: The apparent rarity of hyperbolic comets.—**A. Buhl**: Multipoint movements corresponding to the Schrödinger equation written for the case of a single point.—**C. Courty** and **C. Chéneveau**: The direct measurement of the magnetic susceptibilities of liquids, by the Curie-Chéneveau magnetic balance. Data are given for carbon tetrachloride, chloroform, alcohol, and pyridine.—**T. N. Panay**: The realisation of a black body at the boiling point of metals. A method of obtaining black body radiators at fixed temperatures. Details are given of the construction of a black body radiator working at the boiling point of zinc.—**J. Gilles**: The variation in the wave-length of lines emitted by a copper arc of great intensity. The stability of the arc was ensured by using a brass anode and graphite cathode. Three wave-lengths were studied, 5218, 5153, and 5105. The last showed no change, but the first two showed displacements of the same order.—**F. Wolfers**: The possibility of a Compton effect in optics. From a mathematical study, the trajectories of the photons are reflected and refracted at the surface of separation of two media in such a manner that the frequency of the photons remains invariable. Hence in interference phenomena there is no difficulty due to the Compton effect.—**Marcel Cau**: The interpretation of the experiments of Pogány; the influence of the thickness.—**S. V. Sze**: The magnetic spectrum of the β-rays emitted by $ThC + C' + C''$. Details of measurements of 28 lines, half of which are new.—**Mme. Irène Curie, F. Joliot**, and **P. Savel**: Some experiments on the radiations excited by the α-rays in light bodies. Experiments on the action of the α-rays on lithium and beryllium.—**Francis Perrin**: The possible emission of demi-helions during certain induced radio-activities. The possibility of the existence of a demi-helion, resulting from the reunion of a proton and a neutron (mass 2, charge 1) is discussed, and some consequences deduced.—**Pierre Dubois**: The reduction of permanganate by manganese sulphate. Study of the variations in oxygen content of the precipitate produced by changing the amount of permanganate and the pH of the liquid.—**M. Battegay** and **L. Denivelle**: Aminosulphonamide or sulphamide, $SO_2(NH_2)_2$.—**P. Carré** and **D. Libermann**: Thionylaniline as a reagent in organic chemistry. Its use for the characterisation of acids as anilides. Thionylaniline may serve to identify many acids as anilides. Cases are described for which the method is unsuitable.—**Mailhe** and **Creusot**: The thermal decomposition of isopentane in the presence of silica gel. At 680° C., with silica gel as catalyst, for 15 seconds heating, isopentane gives 75 per cent gaseous products and 25 per cent liquid rich in ethylenic and aromatic hydrocarbons.—**Paul Gaubert**: Tints due to the pleochroism of crystals and of artificially coloured spherolites.—**N. Stoyko**: The periodic displacements of continents. A discussion of the periodic variations of longitudes of various observatories. The period of the variation is about eleven years, the same period as the sunspot variation.—**Ernest Esclangon**: Remarks on the preceding communication.—**G. A. Nadson** and **C. A. Stern**: The action at a distance of metals on micro-organisms. A continuation of previous work on the same subject. The action of the metal is stronger (that is, the colonies developed are fewer) as the atomic number of the metal increases. The possible cause of this action is discussed; it is not due to the production of ozone or of hydrogen peroxide.—**J. M. Lys**: The composition and evolution of the reserves in *Cyclamen latifolium*.—**E. Sollaud**: The development of *Palæmonetes mesopotamicus* compared with that of other *circa*-Mediterranean *Palæmonetes*.—**Emile Terroine, Mlles. Marguerite Champagne** and **Gilberte Mourot**: The distribution of the urinary type of nitrogenous metabolism in various species of mammals during the minimum of specific endogenous discharge.—**Jules Amar**: Conclusions on hydrothermal metabolism.—**A. M. Monnier** and **H. H. Jasper**: The action of the centres on the various characteristics of the nerve fibre. The analogy with electrotonus.—**J. Lignières**: The causes of the attenuation and exaltation of the aphthous virus. Recurrence in aphthous fever. The choice of virus for antiaphthous vaccination.

MELBOURNE

Royal Society of Victoria, April 14.—**G. F. Hill**: Australian *Rhinotermes* (Isoptera). The first two species described, *Rhinotermes intermedius* Brauer and *R. reticulatus* Froggatt, are regarded as being specifically distinct, whilst the remaining hitherto described species, *R. breinli* Hill, is proposed as a subspecies of the former. Three new subspecies are described, namely: *R. intermedius seclusus*, *R.i. actuosus*, and *R.i. derosus*, as in the soldier caste (two forms) of Brauer's species. Comparative measurements of species and subspecies of *Rhinotermes* are given.—**R. B. Withers**: A new genus of fossil king-crabs. The author described a new genus and species of fossil king crabs, *Rutroclypeus junori*, from the Silurian, Kinglake West, Victoria. The relatively large dorsal shield and long tail spine are adaptations to the animal's burrowing habits.—**C. W. Brazenor**: A new record of a beaked whale (*Mesoplodon*) from Victoria. This is the first discovery of *Mesoplodon grayi* Haast on the Victorian coast. The upper half of a skull and two caudal vertebræ were found at Cape Schanck, near Flinders.

ROME

Royal National Academy of the Lincei, Feb. 21.—**U. Cisotti**: Motion with 'wake' of a flexible profile; dynamic actions (2).—**G. Abetti**: Altitude of the chromosphere in 1931. For the mean height of the chromosphere during 1931, observations at Arcetri on 118 days give the value 9·84″, whereas those at Madrid on 29 days give 10·14″. The former indicate diminution of 0·44″ in comparison with 1930, and the latter an increase of 0·33″, the latter result being probably due to the small number of observations made. As was previously noted, the value is highest at the poles and lowest at the equator. The observations at Arcetri, Catania, Madrid, and Zurich show that the total area of the prominences, measured in units of prominence, diminished by 68 from that of 1930, whilst for the preceding year the decrease was 291. In 1931 the maximum frequency of the prominences is shown in both hemispheres at latitude 45°, this being regarded as an indication of the commencement of a new cycle.—**E. Paternò**: (1) Cryoscopy and molecular weight of polymerides of carbohydrates. Cryoscopic determinations of the molecular weights of derivatives of cellulose and analogous products are regarded as valueless.—(2) Cellulose in Schweitzer's reagent. The preparation of a solution of cellulose in Schweitzer's reagent, without previous preparation of this reagent, is described. In this way a solution is obtained which is much richer in cellulose than those made in the ordinary way.—(3) Cellodextrin, amyloids, and pentosans.—**L. Cambi, L. Szegö**, and **A. Cagnasso**:

Magnetic behaviour of complex compounds. (4) Ferric $N:N$-dipropyl dithocarbamates. The results now given refer to the di-n-propyl, n-propyl-isopropyl, and di-isopropyl compounds.—**G. Andreoli**: Reciprocal pairs of V_3: laws of duality of the linear and tangential metrics, of parallelism, and of metrism. (1) Variational problems.—**Patrick Du Val**: Surfaces of one kind which are not bases for a system of quadrics.—**Luisa Pelosi**: Levi-Civita's parallelism.—**C. Antoniani and F. Zanelli**: Investigations in the phytosterol group: Sterols of grape-seed oil. When the crude sterol product of grape-seed oil is subjected to acetylation and bromination according to Windaus's method, a single soluble bromo-acetyl derivative is obtained. The presence of stigmasterol and analogous sterols is thus excluded.—**A. Corbellini and C. Pizzi**: Stereoisomerism of 2 : 2′-disubstituted derivatives of diphenyl. The resolution of 2-[bisphenylmethoxy]-2′-diphenylcarboxylic acid into its optical antipodes is described.—**Z. Jolles**: Diazo-resins (1). Diazo-resins obtained, usually together with the corresponding aromatic hydrocarbons, from the normal diazohydrates of aniline, *m*- and *p*-toluidines, *o*- and *p*-anisidines, *o*- and *p*-phenetidines, *o*- and *p*-aminobenzoic acids, and α-naphthylamine in presence of sodium hydroxide, are described. The nitrogen contents of the products are mostly in good agreement with those calculated from the equation (for aniline), $4C_6H_5.N_2OH = C_{24}H_{18}ON_2 + H_2O + 3N_2$. The resinification seems to result from internal oxidation of the diazo-compounds.—**A. Rossi**: Crystalline structure of praseodymium. X-ray examination by the powder method of a specimen of praseodymium (of 99·4 per cent purity) gives the value 1·62 for the axial ratio $c : a$ and 3·657 A. for the side of the unit cell. The calculated density is 6·777, the experimental value being 6·765 ± 0·008. Good agreement is shown between the calculated and observed intensities of the spectral lines.—**F. V. Madon and S. Goldberger**: The adrenaline blood-sugar curve during fatigue and the potassium-calcium ratio. The experiments described were made on four individuals. Fatigue is accompanied by a marked increase (15-20 per cent) in the potassium content of the blood, the calcium content remaining constant. The influence of fatigue on the action of adrenaline on blood-pressure shows irregular and individual variations. The blood-sugar is, however, always markedly lower after labour than during rest.—**A. Baroni**: Existence of polythionic chlorides: determination of the refractive indices of solutions of sulphur in sulphur chlorides. Measurements have been made of the refractive indices of mixtures of sulphur with sulphur chlorides (SCl_2 and S_2Cl_2) heated to 100°, 150°, or 200°, and of the same mixtures after these have aged for about six months. The results render probable the existence of a polythionic chloride S_3Cl_2, and seem to exclude the existence, within this range of temperature, of compounds richer in sulphur.—**G. Piccardi and A. Sberna**: Molecular spectra and spectroscopic analysis. (3) Investigations on yttrium. Yttrium monoxide, YO, obtained by volatilising any yttrium compound, exists as such in the oxy-hydrogen flame, and yields a spectrum composed solely of bands of the monoxide and free from atomic lines. The orange and red regions show two systems of irresolvable narrow bands with origins at λ5972 and 6132, and a vast system of wide bands with origin at about λ4817, these being resolvable into lines by a powerful apparatus.—**G. Checchia-Rispoli**: *Sanfilippaster*, a new genus of echinoids of the upper cretaceous.—**Zippora Danin**: Gaseous content of the cenobia of *Rivularia polyotis* (J. Ag.) Hauck. The gases secreted in these cavities are similar to those formed in the corresponding cavities of brown and green algæ.

Racial Character and Criminal Responsibility

IT was evident from the moment of the arrest of Paul Gorguloff after the assassination in May last of the President of the French Republic, that the trial would be one in which the expert evidence of the alienist might be expected to have the last word. In the event, owing to the line taken by the prosecution, the case is likely to be of greater significance in relation to fields of scientific research other than morbid psychology. The crime was of a type with which the world has been only too familiar in the last half-century or so. The assassination on Sept. 10, 1898, of the ill-fated Empress Elizabeth of Austria, blameless and universally beloved, will mark for all time the futility and tragedy of such crimes, in which the choice of victim is determined solely by social pre-eminence and the assassin has no specific personal grievance, but is dominated by an overwhelming and violently perverted sense of social injustice, directed impartially against any and all in authority.

Nihilism is no longer in vogue as a mode of political expression. Its place has been taken by other ' isms ', which claim for themselves a more consistently grounded philosophy, but, it may be said incidentally, have a more far-reaching and devastating effect, even if their aim be ostensibly constructive. The individual who by assassinating the ruler of a country, usually not his own, seeks to pave the way to the regeneration of the world—Gorguloff at his trial acclaimed himself as an " apostle "—is now something of a political anachronism. The assessor of his criminality is no longer the statesman, nor the touchstone of his crime the stability of the social order. He has become merely a subject for the alienist.

A defence of insanity in a legal trial places the prosecution in a position of considerable embarrassment. Recent controversy in British medical jurisprudence has been an indication of the difficulties which are experienced in fixing the degree of criminal responsibility in such cases. For, it must be remembered, the legal issue is not insanity *per se*, but responsibility. When the crime is political the difficulties of arriving at the state of mind of the accused at the moment of the criminal act may be enormously increased by prejudice.

Political crime which goes to extremes is, fortunately, rare in Great Britain, and the common-sense view, somewhat phlegmatic, of the British public towards hyper-enthusiastic reformers, as well as the notoriously impartial attitude of judges, law officers,

and courts, have a modifying effect on the heat of political controversy. On the Continent, however, the temper of the public and the atmosphere of the courts, which, as representing the State, are vindicatory rather than judicial, contrive to imbue cases of political crime with a more vital quality in their relation to the everyday life of the average citizen; while the more aggressive methods of political extremists there have too often justified the apprehensions with which the logical consequences of their doctrines are regarded. Expressions of opinion, which in Great Britain would be thought the mere vapourings of a doctrinaire, in France or Spain, for example, will be accepted as a prelude to action of a corresponding violence.

If it is true logically, as well as legally, that it is impossible to indict a whole nation, it is scarcely less true that it cannot be confined to the limits of a generalisation on its psychic characters. Yet in the Dreyfus case, the condemnation of an officer suspected of betraying official secrets to a foreign power, which appeared to the world at large as more than probably a miscarriage of justice, was an almost instinctive reaction of virtually a whole people, which saw itself already defenceless and outmanœuvred, and the overwhelming victory of an enemy force *fait accompli*. A racial capacity for logic may, it seems, readily develop hysteria. On the other hand, Italy's realism grapples drastically with facts as they are. Its methods of attacking social and political problems leave no place for aspirations or theory, unless officially approved. Hence the secret society. In Germany an ideal of pan-Germanic sentiment, in which its youth is sedulously trained, is supreme, however parties may differ as to the best means of its attainment. Here are samples, taken not quite at random perhaps, but none the less significant, of the manner in which different peoples are dominated by psychic constitution in their reaction to a political crisis, and the attitude of mind with which they may be expected to view an act committed for political reasons and with a background of political theory, such as was the assassination of the French President.

It may seem that these speculations on the effect of racial character as a factor in politics have led us rather far from the function of the alienist as the assessor of criminal responsibility. This might be so, were it not for the argument put forward by the prosecution in the trial of Gorguloff.

As was to be expected, the defence entered a plea of insanity, and it is significant of the almost academic method of approach that its principal witness, Dr. Logre, made the admission, which might well have been damaging in certain contingencies, that he personally had not examined the accused. He maintained, however, that the report of Gorguloff's examination showed that he was a border-line case, neither completely responsible nor completely irresponsible. He summarised the mentality of the accused, in what was virtually a characterisation of a type, by saying that he would have certified him as showing " lack of the critical spirit and the sense of responsibility, tendency to paranoia and morbid ideas, megalomania, persecution mania, and the possession of an idea that he had a mission to fulfil, believing himself to be not the saviour of his country alone but of the whole world ". His colleagues, he said, had not taken into account the drama going on in the spirit of the accused man. Gorguloff, who had been consistently incoherent in his frequent interruptions throughout the trial, especially when evidence had been given of his actions as torturer and member of the Cheka at Rostoff, here accepted the doctor's interpretation of his mentality with emotion, declaring with sobs that the doctor understood his soul and that he could now die like an apostle. The last expert witness for the defence was more concise than Dr. Logre. The case, in his opinion, was simple: the prisoner undoubtedly suffered from paranoia, megalomania, and a persecution complex—a case in which one had to be on the look-out for tragedy.

It has seemed desirable to outline the defence out of its proper order so that the remarkable line taken by the prosecution's expert witnesses may be fully appreciated. It is to be noted that they, or at any rate the most important of them, Dr. Genil-Perrin, insisted that no interference or hint had been received from the defence. It is evident, however, that they had anticipated the defence, as, indeed, any expert was bound to do, and that their examination of Gorguloff was directed, perhaps almost unconsciously, to meeting the course it was presumed it would take by finding the basis of an argument which would be conclusive, in the eyes of the court, in proving his sanity.

The line of argument developed by Dr. Genil-Perrin was that Gorguloff was a native of the Caucasus, " a country where the people lived among myth and legend ", and belonged to a different and " perhaps ill-assimilated civilisation " ; while the atmosphere of terrorist Russia may have predisposed him to acts of violence. He was, therefore, to be regarded as responsible. In other words, the witness's contention was that in assessing the degree of responsibility in an apparently abnormal mentality, race and culture must be taken into account.

young child's usual creeping, and obviously suggestive of the walking of gorilla, chimpanzee, and orang utan, when these apes are on all fours and not trying to be bipedal. There is this difference, however, that these apes rest their fore weight on their knuckles, and that the orang rests its hind weight on the outer edge of its foot.

Hrdlička began to search for other examples of quadrupoid infants, and he has been gradually rewarded by finding 387 cases, 369 white and 18 coloured. He has also collected a number of references to this unusual mode of progression, but few of these seem to us to be of more than bibliographical interest, most of them being very vague in their description of what the actual movements were. Of Hrdlička's cases, 331 are more or less satisfactory, but the number is relatively small for the time given to collecting, and indicates that running about on all fours is not of frequent occurrence.

The phrase 'on all fours' is often colloquially applied to children levering themselves along the nursery floor on their hands and knees, or in some modification of creeping and crawling; but Hrdlička rightly restricts it to those cases where the hands and feet are pressed more or less flat on the ground, while the knees are off it. It is a kind of locomotion comparable to that of a bear or some other plantigrade mammal going on all fours. One must not, of course, press the conformity to the defined type too hard, for the phenomenon is a variable variation and has different degrees of expression. Thus the hands are occasionally flexed; in rare cases there may even be a use of the knuckles; or the anterior contact with the ground may be restricted to the fingers. Similarly, the part of the foot behind the toes may be off the ground, especially when the child is putting on speed. There are many oscillations within the variation; yet there are few, if any, of the photographs submitted that could be mistaken for a moment for the common 'hands and knees' progression. It is interesting to notice that the 'all fours' method may precede the 'hands and knees' method, or succeed it, or alternate with it; but if it occurs at all, it is usually the only (recorded) way of moving before the child begins to toddle.

The 'all fours' children are almost always vigorous in body and mind; they move with striking rapidity and show more than average power of balance; after becoming bipedal they may occasionally return to the quadrupedal method, which is for a while quicker than toddling; in a few cases the habit may be prolonged to the age of five years,

Smithsonian Institution, Washington, 1

The question arises as to the nature of t
ence from the usual modes of locomotion
before they begin to be bipedal. But the
must remain to some extent a matter
until the data are more numerous. Hr
gards it as an individual recapitulation of
human mode of progression, such as is s
gorilla, chimpanzee, and orang utan, with
differences already noted, or in baboons
monkeys, where the hands and feet are plant
more or less flat on the ground.

The difficulty is the relatively rare manifestat of the peculiarity, so far as we know, for its expression is certainly not part of a normal ontogenetic recapitulation of a phylogenetic stage. It seems to be casual. The author is disinclined to regard it as a reversion or atavism in the strict sense, that is, as due to the reactivation of a hereditary factor which is normally dormant. When one thinks of it, it is a far cry back to a plantigrade primate ancestry, and the 'all fours' method is itself, as we have mentioned, somewhat variable in its expression. The author concl

Adsorption Data

The Sorption of Gases and Vapours by Solids. By Prof. J. W. McBain. (Twentieth-Century Chemistry, 4.) Pp. xii + 577. (London: George Routledge and Sons, Ltd., 1931.) 25*s.* net.

RECENTLY it has been stated that on the average a paper on adsorption appears every
.v in the year. Prof. J. W. McBain's volume is a
.iece of collection, codification, and classifi-
.ch data. It is divided into three parts,
.y section, the experimental data,
.es and theories of sorption.
(pp. 33-426), which is certainly
.la...n on the subject ever
. comprehensive
.harcoal and
.nt of
.n-

plete, but also extremely interesting to read, as the author has from time to time inserted personal comments and criticism. It is, on the other hand, not so satisfactory if regarded as an introduction to the third section, which includes the theories of adsorption. The reviewer has found it very difficult 'to see the wood for the trees'. To take only two examples. We know with some degree of certainty that practically all cases of adsorption are accompanied by a penetration of the gas or vapour into the interior of the solid by processes which may include space-lattice diffusion, persorption through molecular sieves, intergranular diffusion and capillary penetration, and it is indeed to Prof. McBain himself that we are largely indebted for a proper appreciation of the importance of this phenomenon. Again, from the work of Dewar on the oxygen charcoal system, of Ostwald and Langmuir on the system $CaO - CO_2$, it was clear that at least two states of adsorption existed. The work of Benton and of Nikitin has revealed another state, the existence of which has been confirmed by the more recent work of H. S. Taylor and of Garner. These three types of adsorption, sometimes termed Van der Waals' adsorption, activated adsorption, and chemi-adsorption respectively, all exhibit their own peculiar characteristics, and examples of all three types can indeed occur in certain systems when taken over a sufficiently wide range of temperature. Whilst the actual facts are presented to the reader, a dissection of the data by Prof. McBain, or even an arrangement of the data in such a manner so as to exemplify those points, would provide a reader with a valuable introduction to the theoretical section.

In the theoretical section, the author subjects the hypothesis of adsorption in multimolecular layers to a somewhat detailed analysis, concluding that Langmuir's hypothesis of monomolecular adsorption is adequate to fit all the data which have been established with sufficient degree of certainty. The discussion on the more recent developments of Langmuir's original hypothesis, such as surface mobility and the necessity for energies of activation after 'primary' adsorption, is particularly interesting. More might have been included in the section on active patches and promoters, on the importance of lattice spacing as distinct from isolated atoms or configuration as factors in reaction at or with a surface.

The volume is full of most interesting information clearly presented, and can certainly be recommended to all those who are interested in the phenomena of sorption. ERIC K. RIDEAL.

Short Reviews

Bacteriological Control of Milk: a Practical Guide for Media Preparation and Milk Testing. By A. G. House. Pp. vii + 59. (Reading: The National Institute for Research in Dairying, 1931.) 3*s.* 6*d.*

THIS practical little book contains much useful information on routine bacteriological testing of milk samples. The section on sterilisation is admirable, though it is rather surprising that electrical apparatus, particularly for hot air sterilisation, is not mentioned. Media-making is an art in which precise details always vary according to the experience of the particular technician practising it. To the present reviewer, Mr. House's technique seems in several directions over-elaborate. To mention only one point: in filling media into test tubes, pouring through a small funnel is simpler than the use of a previously sterilised syphon apparatus.

The obsolete titration method of standardising media is described, as well as the *p*H method. It is stated that media can be sufficiently cleared by steaming, but where final sterilisation is done in the autoclave there will be further precipitation, and a preliminary autoclaving is therefore better practice. However, no two technicians will ever agree on such points, or be induced to depart from their favourite methods.

The directions for the actual testing and for the collection and transmission of samples are clearly given. Lactose bile-salt cultures should surely be incubated for three days rather than 48 hours before being regarded as 'negative'. Mr. House very properly relegates the reductase test to its true position as a rough sorting test only. Useful lists of apparatus and equipment are given in an appendix.

R. F. H.

The Keys of Power: a Study of Indian Ritual and Belief. By J. Abbott. Pp. xi + 560. (London: Methuen and Co., Ltd., 1932.) 21*s.* net.

MR. ABBOTT is concerned neither with the religion of the Prophet nor with the animistic concepts of Hinduism, but deals only with the far older underlying belief in a universal supernatural cosmic power which lies behind phenomena and has determined the ritual and practice of the natives of India from time immemorial. Unfortunately, the conservatism of India, which has preserved this ritual unchanged for so long, is not now operative in every department of human activity. Mr. Abbott has to record that the traditional customs, for example, of agriculture, are rapidly passing away. He himself in the last decade has witnessed, in the Deccan, customs discarded by the younger generation and left to the older to preserve; while in Gujerat and Sind the changes have been great. The anthropologist, therefore, will be all the more grateful to him for his assiduity in collecting the large amount of detailed information recorded in this book relating to the manifestation of 'power', or 'mana', as accepted by Mahommedan and Hindu alike, and the ritual which this belief entails in every depart-

Insect Pests of Farm, Garden and Orchard. By Prof. E. Dwight Sanderson. Third edition, revised and enlarged by Prof. L. M. Peairs. Pp. vii + 568. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1931.) 13*s.* net.

WE welcome the appearance of the third edition of this standard book, which has justly enjoyed popularity as being one of the best manuals dealing with North American agricultural pests. It is similar in general arrangement to its forerunners and contains about the same amount of subject matter, but, owing to the larger page employed, the total number of pages is considerably reduced. Only a few of the articles written by Prof. Dwight Sanderson in the first edition remain more or less unaltered. For the rest, the book has been largely rewritten by Prof. L. M. Peairs, who has embodied the results of recent investigations and included a number of new illustrations. As stated in the preface, the edition is properly that of Prof. Peairs, although the name of the original author is retained.

the Medical Research Council began its
ghteen years ago, then, and indeed for some
later, rickets was regarded by many of the
best authorities in Europe as a chronic infective disease of which the infective agent was unidentified. It was called on the Continent the 'English disease' because it was first described in England and because of its abundance in our smoky cities. The disease consists most prominently in the failure of the calcifying process that gives hardness and strength to the bones and to the teeth, and the rickety child is stunted, deformed and enfeebled in various degrees. Before the War it was estimated that in our cities at least one child in every three had obvious signs of rickets. Dr. Mellanby discovered, by laborious experimental work, that rickets is simply a deficiency disease due to the lack in the food of a particular constituent, now called vitamin D. The proper supply of this prevented rickets or rapidly cured rickets already present. Familiar now as this is, even to laymen, it was greeted at first and for some years by much scepticism in many medical circles.

This discovery has led to a remarkable series of developments. It had been found that sunshine upon the body also prevented or cured rickets, that it was the short ultra-violet rays that had this action, and that it could also be produced by
ificial light. But these rays cannot penetrate
han a tiny thickness of skin, and their action
fore be upon something at or very near

fat called cholesterol.
now become an
that this
terol
re

pertinent metaphor for Dr. Rosenheim at the National Institute for Medical Research) found with Mr. T. A. Webster that it was not cholesterol itself that gave this result but a related substance, present with it in much smaller quantities. This, after exchange of results and ideas with Prof. A. Windaus of Göttingen, was identified as a sterol called ergosterol, previously known only as the characteristic sterol of certain fungi and of yeast.

Now the problem became one for intensive study by physicists, organic chemists and biologists working in intimate collaboration. A team of this kind, working under the general leadership of Dr. R. B. Bourdillon at the National Institute for Medical Research, obtained a crystalline substance of very high antirachitic activity by the physical process of distillation in a high vacuum; and another team under Prof. Windaus, in Germany, obtained a very similar substance by a selective chemical reaction. Both of these, however, proved to be compounds of the vitamin with inert substances; and Dr. R. K. Callow, of the National Institute group, found a method of separating the vitamin from either as a crystalline ester, from which the pure vitamin can be liberated. It proves to be itself a sterol, differing from the parent ergosterol only in a detail of the structural arrangement of its atoms, and it has been given the chemical name 'calciferol'. In pure form this has almost incredible biological potency. A single ounce of it would suffice to give a full daily ration for a million growing children.

It is to be noted that this devotion of physicists and chemists to a medical problem has done more than assist medical knowledge. It has yielded additions to both physical and chemical methods. A new form of photoelectric microphotometer which multiplied five-fold the speed of observations was produced in its course, together with a new type of spectrograph. Important new contributions have been made and are still being made to our knowledge of the pure chemistry of the group of sterol compounds. In deciding between alternative possibilities of structure for these complex molecules, the chemist is becoming more and more dependent on the physicist for measurements made by the methods of X-ray analysis.

Now this progressive work, interesting as it is, is not only a clever physico-chemical exploration of academic interest. The results of this intensive laboratory work take on at once a direct bearing upon the practical needs of the community. Accurate knowledge of the vitamin allows adequate standardisation of its amount in different foodstuffs, in terms of a fixed standard of reference. Its artificial production, moreover, brings into action, or should bring into action, the medical administrator, who should be concerned to see that so long as social or economic factors maintain, as they do, an effective shortage of the natural sources of the vitamin among our city populations, a supply

of it by means of the new methods we now have at command shall be made available for every growing child and every child-bearing mother in the country.

There still remains for study the attractive physico-chemical problem of how it is exactly that this calciferol molecule exerts its special influence upon the living cells of the intestinal walls and exactly why, without it, they cannot do their work of effecting the passage of calcium salts into the blood from the food but not back again. Of this we now know almost nothing. Here our task is to attempt further steps towards better knowledge of the mysterious microcosm of the living cell substance.

Other fascinating vistas are in sight. Only in the last few weeks workers in the physico-chemical laboratory at Cambridge have found some evidence that the action of particular wave-lengths of light in developing vitamin D from its precursor substance may not be, as we had been thinking, an isolated phenomenon. They have obtained some indications that, just as for this, so in the case of two other vitamins—each in its own way indispensable for animal life—particular wave-lengths of light may produce the vitamin from its precursor while other wave-lengths close to them destroy it. What we know already of the chemistry of the vitamins having these special relationships to light shows that they belong to widely different types of chemical compounds. If the indications just given should be confirmed, it will seem to be, so to speak, more than a mere coincidence that in two or three different directions at least the animal cell has come to be vitally dependent upon different individual chemical substances, of which each has these remarkable photochemical properties. We should have to consider that we have here perhaps taken our first step towards knowledge of a phase of evolutionary development that has not been dreamed of hitherto, a development made manifest in a highly specialised and detailed adaptation of living matter to its age-long environment of light.

In quite another direction, the growing demands of medical research for intensive physico-chemical studies may be illustrated. Among the varieties of parasitic life that infest the animal body, I mentioned the so-called viruses that cause devastating diseases in man, in animals, and in plants. The loss they cause in life and in money has a magnitude almost beyond calculation. They cause smallpox, measles, infantile paralysis, and many other diseases in man. They cause foot-and-mouth disease of cattle, swine fever, fowl-pox, and other devastating plagues in animals. They cause ruinous diseases in vegetable crops of many kinds, from potatoes in Great Britain to bananas in the tropics. They are called 'viruses' at present because that commits us to no decision as to their nature. What do we know about them ? In a fluid containing them they can be shown to be freely suspended and particulate bodies, for the fluid can be freed from them by rapidly spinning it in a tube so that the particles are driven to one end of it. The bacteria themselves vary widely in size as animals do. None of them can be seen with the unaided eye, and taking the largest as enlarged to the size of a horse the smallest would then be represented by a mouse—and would be near the extreme limit of our highest powers of direct microscopic vision. The viruses are so small, however, that they pass through porcelain filters that retain all bacteria, and they are just upon or beyond the border-line of direct vision by ordinary microscopic means.

Here again medical research has had to call for the intensive application of new physical methods of study. By using the shorter wave-lengths of ultra-violet light the limits of clear microscopic vision can be extended, though this involves using quartz instead of glass throughout the optical apparatus, and obtaining photographic images instead of using direct vision by the eye. It is desirable to photograph the virus bodies in their natural state undisturbed by chemical agents or by stains which by coating their surface alter their apparent size. These methods are already being successfully applied at the National Institute for Medical Research by Mr. J. E. Barnard, who has been foremost in developing them. Another physical problem has been to devise suitable filters with apertures of known size and uniformity so that the different viruses may be graded in order of magnitude and the work of separating them in the laboratory made constant and accurate. This problem has been largely solved already by Dr. W. J. Elford, also at the National Institute, who has found how to produce accurately graded and uniform filters by making collodion films under precisely controlled conditions.

Many of the known viruses have already been arranged in an order of size, and the results gained by optical and filtering methods, which are constant, agree closely where they can be compared. They show that the viruses vary in size nearly as widely as the bacteria do. The largest are close in size to the smallest bacteria, and they descend to the virus of foot-and-mouth disease, of which the particles are little larger than the colloidal aggregates of oxyhæmoglobin in solution. There is probably not room in each particle for more than two or three hundred protein molecules. They can be present in immense number, and yet very few of them are enough to carry full potency. The fluid from a case of foot-and-mouth disease can be diluted ten million times and yet be potent to reproduce the disease.

There are many reasons for considering the viruses to be the smallest forms of life and for allowing them to be living organisms. But there are many unsolved difficulties here. The particles are far smaller than the simplest living cells which have hitherto been regarded as the smallest organisations of living matter endowed with specific character and the power of self-production. It is not certain that a virus can multiply outside a living animal or plant cell : inside it they may multiply with such rapidity as to make it tempting to think that the new particles are being formed not by the growth and a doubling subdivision of their

own substance, but directly, and by some more rapid transformation of matter, out of the substance itself of the living cell containing them. In other words, it may perhaps be as true to say that the disease causes the virus as that the virus causes the disease.

Here again we notice how great is the intellectual interest offered to the physico-chemical student, quite apart from any incentive given by the gigantic practical benefits that will certainly be the reward of successful work in this field. It may be that in the study of these minute forms we are destined to find new clues to some of the most fundamental properties of living matter, and to express them in terms of physics and chemistry. It is perhaps just as likely that we may find ourselves able instead only to express physics and chemistry at this point in terms of life.

It is obviously most urgently desirable that we should increase our knowledge of these tiny forms and the laws of their behaviour as rapidly and fully as possible, if only with the direct utilitarian object of protecting the life and property they attack upon such an immense scale. We have to remember, too, that beyond a doubt some forms at least of malignant disease can be propagated by minute particles of matter which have all the known characters of the viruses. That being so, it is hard not to believe that the right clue to the problem of cancer lies here, and it is in fact being devotedly pursued from that point of view.

I might give many other examples of the great refinements now attained in many directions of biological and medical work. For study of the electrical changes in rapid muscular movement, the physiologist Einthoven introduced the string galvanometer which has been so useful in the hands of Sir Thomas Lewis and others in recording and analysing the successive events in the beat of the heart, normal or disordered. This instrument has passed as a contribution from biology to the regular uses of the physical laboratory. New devices of amplification by the physicists, on the other hand, have allowed Dr. Matthews at Cambridge to follow and measure the curve of electric change due to the passage of an impulse along a single nerve fibre, while Dr. E. D. Adrian there obtains an audible record by a loud-speaker of the impulse, for example, which passes along the optic nerve of a fish when a brief shadow flits across its retina. Prof. A. V. Hill follows the course of the heat changes due to the train of transient and minute chemical changes in nerve fibres that propagate the nervous impulse and measures them with an accuracy expressed in millionths of a temperature degree. The biologist, if given two samples of crystallised egg albumen from the eggs of a duck and hen respectively, can tell, by means of a biological test, which of them comes from which bird with great rapidity and certainty, though the detection depends on a subtle difference of molecular pattern far beyond the reach of any analysis by the chemist. Dr. Todd, at the National Institute at Hampstead, again, has shown that the interactions of the blood between fowl and fowl can be so used as to enable the biologist if he desires it to identify any given hen and its family from any other hen in the world. No organic chemist has ever dreamed of performing in such subtlety as that.

Medical progress, however, is greatly hampered by various circumstances that keep from its services many of the able men who are best fitted to enjoy giving their life-work to advancing it.

One of the most serious of these is the unfortunate and harmful tendency both in the schools and in the universities to segregate physicists and chemists on one hand from biologists on the other. At the schools this is largely the result of the scholarship system. It is found easier to cram clever boys along narrow specialist lines in physics and chemistry for scholarships at the universities, while the universities have never taken effective action so to use the scholarship system as to secure a well-balanced scientific education for scholarship candidates. The result is twofold. The cleverer boys are diverted from biology, while the biologists, if any, must give up proper training in the physical subjects and themselves specialise narrowly if they are to have any chance of scholarship success. The system of university examinations at both Oxford and Cambridge encourages still further this segregation of the sciences, and at Cambridge changes in regulations during the last twenty years have made the position worse rather than better. These are not only personal views drawn from my own experience; the same opinions have been strongly expressed by Lord Chelmsford's Committee, appointed in 1930 by the Prime Minister to consider the obstacles which stand in the way of the education and supply of biologists for work in Great Britain and overseas.*

I must not enter further upon this educational question now. I want only to urge here that the general cause of medical research suffers greatly from the present wide and unnecessary divorce, during the earliest stages of education and onwards, between those taught on the physical side and those upon the biological side. It is wholly indefensible on any ground that schoolboys and undergraduates who have special aptitudes for physical inquiry should be confined by a faulty system to the study of non-living matter only. The problems of the living cell are at least as attractive to a keen mind as those of non-living matter, and they demand perhaps greater rather than less manipulative and analytical skill, because of the instability of the living substance that is studied.

Medicine has always been the mother of sciences, and we may remember that it was from the body of medicine, namely from the schools of physiology, and not from schools of organic chemistry, that biochemistry was born and developed as an organised university discipline. It has been found indeed as the result of experience that the man trained narrowly in organic chemistry does not in general make the best biochemist. Without earlier acquaintance with the problems of living things, he

* Report of the Committee upon Education and Supply of Biologists. H.M. Stationery Office Publications, 63-75, 1932. Price 1s.

is less likely to break new ground than the biologist starting far behind him in purely chemical equipment. There is pressing need now for a parallel development of bio-physics, not necessarily, or even desirably, as a separate discipline, but by a breaking down of the present artificial educational barriers between physics and physiology, barriers so unworthy of the Greek spirit of which those very names remind us.

I must not stay to speak of still another set of conditions that handicap medical progress. Of those biologists who pass on to hospital work and the study of disease as such, many who are among the fittest to make new knowledge in the sphere of clinical medicine are tempted to turn aside from the arduous path of new investigation, either because of the absorbing human interest of professional work or again because of their financial needs or desires.

The mastery over non-living matter which physical science has given us has transformed all the conditions of human life within a century, but the conveniences offered by improved transport and improved communications have brought only superficial changes, and it is doubtful whether they have done on the whole greater service or disservice to the happiness and well-being of mankind. Our improved powers of producing wealth, as the whole world is now observing, seem already to have outrun lamentably our powers either of wisely using or even of retaining it. It is better mastery over living matter, and the improvement of the bodily and mental powers of man, that are needed for the real betterment and enrichment of the race. By powers of a kind that we are already in process of gaining by medical research we may hope to transform human life in ways almost unimagined now and to make a new world indeed.

Without entering into dreams of the far future we know that here and now the campaign of medical research is improving our estate. Its progress and success have immediate interest for all of us and the highest claims upon the goodwill of all mankind. It is a campaign to diminish pain, to lessen the waste of human effort and human life, and to enrich and enlarge the powers of the human body and mind.

York Meeting of the British Association

THE full programme of the York meeting of the British Association is approaching completion, and should be in the hands of members very shortly. A change of practice has been instituted with the view of economy and greater convenience. The "Programme and Daily Timetable" will embody the usual features both of the Association's list of transactions and of the so-called local programme formerly issued by the authorities at the place of meeting. Between these two publications there was always a measure of overlapping; moreover, the local programme was never in the hands of members until their arrival at the meeting. Now, following the practice initiated at last year's centenary meeting, when the whole organisation was centred at Burlington House, it becomes possible to place fuller advance information in the hands of members whose intention to attend, and postal addresses, are known.

Another and still more important change of practice with the same objects is initiated this year. It had become the custom, as is well known, for local committees to prepare handbooks for the successive places of meeting. Some of these have become standard reference-books of material value; on the other hand, the series followed no definite plan, and these books, again, were issued only at the meeting, and were sometimes very costly to produce. It is known that they did not always receive from members the attention they deserved: there is a case on record of a copy of the local handbook being seen on a second-hand bookstall in the place of meeting almost immediately after its issue. For the present year, a short "Scientific Survey of York and District" has been prepared by recognised authorities through the London office, with the collaboration of the appropriate sectional officers and the York executive. This also will be issued, so far as possible, to members in advance, and they will thus have the opportunity of priming themselves with information about the locality before they visit it. It is intended afterwards to include this "Survey" in the Annual Report, and if the present issue is found to form a satisfactory model, there will gradually accumulate, as the Association meets in successive centres, a systematic series of local scientific studies.

In these directions, at least, the Association has travelled far from the practice of twenty years ago, when the meeting was announced by a single leaflet, and members were left to find all other information at the meeting itself. Certainly the Association has become more businesslike (if the epithet may be permitted) in the formulation and announcement of its programmes. The main lines of the sectional transactions are laid down at the joint meeting of the organising sectional committees in January. The value of this meeting, which was initiated at the instance of the former general treasurer, the late Dr. E. H. Griffiths, has been, from the point of view of administration, immense, and it is believed to be the general opinion that it offers a most useful occasion for the really hard labourers in the Association's vineyard to keep in personal touch during the interval between the annual meetings.

As a result, the principal features of the meeting were known in broad outline when the "Preliminary Programme" was issued and noticed in NATURE for April 30, p. 642. Not many important corrections are made. The title of Lord Rothschild's presidential address to Section D (Zoology), not then announced, is now known to be "The Pioneer Work of the Systematist". The evening discourses by Sir Arthur Hill and Mr. C. C. Paterson have been transferred from the Exhibition Hall, which is found unsuitable for lanterns and demonstrations, to the less commodious but more

intimate Co-operative Hall, where, to obviate overcrowding, special tickets will be required (an unusual practice, which members are asked to note). The discussion on the university movement in Yorkshire, originally announced provisionally in Section L (Education), will not take place. For the rest, the full programme in no way falls below its predecessors in general interest. As compared with the York meetings of 1881 and 1906 (and indeed with later meetings) there is to be observed the widening of the tendency of sections to lay out their programmes and group their communications under definite broad headings. This is a movement appreciated by the informed public which it is one of the functions of the Association to address: the method gives a clear view, from year to year, of directions in which the main lines of scientific advancement are being laid down; and if the Association should be tending to leave the highly specialised individual communication to other more specialised media (and probably, on balance, there is such a tendency), the meetings should not on that account become less valuable to scientific workers. As occasions for personal contacts, these meetings are unique. To take a single illustration from the present programme, it is difficult to imagine another organisation which would give opportunity for a joint discussion of common problems between physicists and psychologists.

In the previous article on the York meeting in these pages, it was stated that many points of interest in the neighbourhood would be visited, and that no locality is richer in them. The full programme bears out this statement. In York itself there are all the antiquarian interests of the city. There are the cocoa and chocolate works of Messrs. Rowntree and Messrs. Terry, at both of which special receptions are being arranged. There are the museum, the carriage works, and the signalling school of the London and North Eastern Railway, the scientific instrument works of Messrs. Cooke, Troughton and Sims, and glass, aircraft, electrical, and other works. Taking a radius from York to the east coast, Hull, Leeds, and the Pennines, there are geological, botanical, zoological, archæological, industrial, and educational interests of the widest variety, of which the various sections which arrange their own excursions will take full advantage. The general excursions, mainly, as usual, on the Saturday, will combine railway and road travel in a manner not without significance when these methods of transport are elsewhere so strongly in opposition; there will also be occasions for relaxation on the River Ouse.

It might have been feared—indeed, it was feared—that the difficulties of the present time might react unfavourably on the attendance at the meeting. It is never known until the meeting itself what amount of local support by way of membership will be forthcoming: it is to be hoped that it will be ample at York. But so far as concerns the attendance of visiting members, as registered from day to day in the London office, there is no evidence of any enforced diminution of interest.

Lastly, these same difficulties, as suggested at the beginning of this article, have dictated economy in the working of the meeting. Traditions expensive to maintain had been handed on from one locality which entertained the Association to the next. The Council was instructed by the General Committee at the centenary meeting last year to review the cost of meetings falling upon local funds, and to suggest measures for its reduction. This has been done. The steps taken in cooperation with the York executive will not affect the Association's own funds in the direction of saving—they may, indeed, have a contrary result. But they will render the Association this year, and, it is to be hoped, in future, a less exacting guest than it used to be, and that without any diminution in the scientific value of its proceedings.

Obituary

SIR RICHARD THRELFALL, G.B.E., F.R.S.

NO one who knew Threlfall is likely to forget him: his robust personality, his bonhomie, his humour, his gift of vivid expression, his energy, his driving force, his power of telling a good story and of making a good speech, together with his massive frame, made an impression not easily effaced. Those who knew him most intimately knew that besides all this he was the staunchest and most helpful of friends, one on whose help they could rely in good times or bad, and whose death has taken from them a prop on which they had often leaned.

Threlfall was born at Hollowforth, a village near Preston, on Aug. 14, 1861, and in due time went to Clifton. Here his tastes soon became apparent; explosives were his first love, and legends about his adventures in practical chemistry still float about; one of these is that he conceived the idea of felling trees by the aid of dynamite and tried it on a young fir tree just outside the school, with the result that the tree was shot through the window of the school laboratory. Once when he was working at home during the Easter holidays, in a small laboratory which his father had fitted up, he had an explosion which blew off the third and little finger of his left hand and a good deal of the hand at the back of them, as well as the top joints of the right thumb and index finger. It was characteristic of him that before being driven into Preston to have his wounds dressed, he asked his mother to get a piece of wood and put it between his teeth so as to keep his mouth open. He said if he did get lockjaw he was not going to be starved to death as well. In spite of the loss of half his fingers he became one of the best manipulators and glass-blowers of his time, and wrote a book on laboratory arts. He was in the Rugby XV. at Clifton, and also shot for the School.

He left Clifton in 1880 and entered Caius College,

Cambridge, where he had won an entrance scholarship. Among the scholars of Caius in his time were many who attained great distinction, including Sir Charles Sherrington; the regius professor of civil law at Cambridge; and the Master of Emmanuel College. He took a 1st class in Part I. of the Natural Sciences Tripos in 1882, and again he was in distinguished company, for with him were Adami, Bateson, H. H. Head, Harker, Harmer, and Shipley, who all, like himself, became fellows of the Royal Society. Between the first and second parts of the Tripos he spent a semester at the University of Strassburg and worked under Profs. Fittig and Kundt. It was about this time that he constructed an automatic microtome. The history of this discovery is given in *Biological Reviews* of October 1930.

In 1884, Threlfall took a first-class in Part II. of the Natural Sciences Tripos. He was very prominent in undergraduate life, and played twice in the Rugby XV. against Oxford. In those days a 'blue' was not given in Cambridge for Rugby football, though it was in Oxford. The Rugby team was naturally up in arms, and said that if the 'blue' was not given to them they would take it for themselves. This brought all the wigs on the green, and in 1885 a meeting to which all members of the University were admitted was held at the rooms of the Union Society. The room was so crowded for some time before the proceedings began that when Threlfall, on whom the hopes of the Rugby supporters rested, arrived, he could not get beyond the crowd at the back of the hall, and had to be held up by some friends while he made his speech. The speakers before him delivered carefully prepared speeches which smelt very much of the lamp and left the audience quite cold. When he got up and jerked out from his uncomfortable stance one short sentence after another, full of good sense, good humour, and good jokes, he soon had the house rocking with laughter, and put the issue beyond doubt. I never heard a speech which had so much influence on the division. About this time he was Hercules in the "Birds" of Aristophanes, the second Greek play produced at Cambridge, and certainly looked the part.

Threlfall had worked at the Cavendish Laboratory while an undergraduate, and after taking his degree began systematic research work. He and I collaborated in some investigations, and I soon realised his quite exceptional skill as an experimenter. He was a demonstrator in the Laboratory for a short time, but left Cambridge in 1886 to take up the professorship of physics in the University of Sydney. When he arrived at the University and asked where the Physical Laboratory was, he was told there was no laboratory. Then he said he was going back to England, as he was not going to be a professor of physics without a laboratory; so they took him over the building and showed him a room here and another room there which might perhaps be spared to make the laboratory. When he said he was not going to have a laboratory of that kind, they offered to try to get the funds from the Government, but for a long time nothing materialised.

Threlfall had in the meantime become very friendly with the Prime Minister, and kept pressing upon him the claims of the laboratory, without any immediate result. One night, however, the Prime Minister came up to him at the club and said, "Dick, I have done the square thing by you at last. I've put your laboratory on the estimates. We've just been beaten on a division, and are resigning to-morrow, so that the other fellows will have to pay." The other fellows did pay, and Threlfall got a laboratory which at the time it was completed was at least as good as any in the world.

He had many amusing experiences in Australia. Once when he and the professor of geology were travelling together, they were surprised, when they arrived at a small town, to be welcomed by a band which struck up "See the conquering hero comes". The geologist said, the people here have evidently got some mine they want to boom, and are doing this to induce me to give them a good report. This seemed reasonable, but when they got to close quarters, it turned out that the people had mistaken Threlfall for Donald Dinnie, a famous Scotch athlete, who for many years had been the 'star' performer at Highland gatherings and could 'toss the caber' farther than anyone else had ever tossed it, and was at this time touring New South Wales. The geologist asked who they thought he was, and they said they thought he was the man who went round with the hat after the performance.

As soon as the laboratory was finished, Threlfall began to experiment, and many important researches by himself, his colleagues, and pupils were made during his tenure of the professorship. I hope at another time to give a detailed account of his contributions to physics, but I shall now confine myself to personal reminiscences. I may mention here, however, his experiments made on quite an engineering scale on the velocity of transmission of violent explosions through sea-water, and the work he did as chairman of the N.S.W. Royal Commission on the causes of the spontaneous combustion of coal in ships.

In addition to his more conventional duties, Threlfall played in the Rugby XV. of the University of Sydney.

Threlfall returned to England in 1899 and joined the well-known chemical manufacturing firm of Albright and Wilson at Oldbury, near Birmingham, the largest producers of phosphorus in England. The knowledge of phosphorus and its properties which Threlfall acquired at Oldbury were of vital importance to the country when War broke out. In 1905 he was elected an honorary fellow of Caius College, on the same day as Sir Charles Sherrington. He had been elected a fellow of the Royal Society in 1899.

Threlfall's qualities first found opportunities for their full development during the War. He threw himself with the greatest ardour into the work of applying chemistry to the needs of the Army, Navy, and Air Force. His qualifications for this were unique; he knew chemistry from the point of view of the manufacturer as well as of the professor, and

he had at the works at Oldbury great facilities for carrying out experiments on a large scale with the least possible delay. His powers of work, his ability to get results quickly, his energy and enthusiasm were quite extraordinary. He served on the Board of Invention and Research under Lord Fisher, on the Advisory Council for Scientific and Industrial Research, on the Trench Warfare Committee, and devoted practically all his time to work for the nation. I was on the Central Committee of the Board of Invention and know what he did for that Board alone. The committee met every week, and more often than not we had a report from him on some question that we had asked him to investigate, or gave him a new problem on which we wished for a report. His development of smoke screen and the tracer bullet were of vital importance in the War. For these services he was made K.B.E. in 1917 and G.B.E. in 1927, and never were these honours better earned.

After the War, Threlfall continued to spend a very large amount of time and work on the affairs of the Department of Scientific and Industrial Research, of which his great friend Sir William McCormack was chairman. He succeeded Sir George Beilby as chairman of the Fuel Research Board, and in 1919 went on a mission for the department to Japan. He also, after the War, spent a good deal of time and money on experiments on the effect of great pressure on carbon, as Moissan claimed to have produced diamonds in this way. Sir Charles Parsons was also about this time working by a method of his own on the same subject; neither were successful in producing diamonds, and they came independently to the conclusion, which I believe is now generally accepted, that Moissan was mistaken in the interpretation of his results. Threlfall also took up again a research which he had commenced when in Australia, that of measuring the variation of gravity at different places by means of a quartz torsion-balance.

Threlfall's published papers, good as they are, give a very inadequate idea of the amount or importance of his work, the most important part of which was done for the War or for the application of science to industry. This was known to few, and no account of it appeared in scientific papers; it is to be hoped that steps will be taken to keep it in remembrance.

He was nearly as keen about his amusements as about his work; he was fond of shooting and fishing, and was a good shot with both gun and rifle and an excellent fisherman. He was also the most sociable and 'clubbable' of men: he thoroughly enjoyed the meetings of the Royal Society Club, the Old Boys' dinners at Caius College, the Cavendish Laboratory dinner, or a dinner with a friend or two at the Athenæum; he enjoyed the dinner itself as well as the company. He was an excellent after-dinner speaker; his strong personality came out in this as in everything he did, and his speeches had a freshness and vigour all his own.

In April 1930 he had a serious illness, and though he recovered sufficiently to get about again, his health gradually declined, and on July 10 he died at his house in Edgbaston. He married in 1890, when he was professor at the University of Sydney, Evelyn Agnes, daughter of John Forster Baird of Bowmont Hill, Northumberland. Lady Threlfall died in 1929, leaving four sons and two daughters.

J. J. T.

I FIRST met Sir Richard Threlfall during the War, when he came to witness trials of his phosphorus smoke bombs. During the last year of the War I was in close touch with him, as he was busily engaged on other experimental work of importance to the Air Force, and frequently visited Col. Bertram Hopkinson, who was then in charge of experimental and research work for the Air Force. He was a great friend of Bertram Hopkinson; he had also been an intimate friend of his father, John Hopkinson. He often spoke to me about them in later years, and evidently held them in affectionate memory.

The particular work of Threlfall's with which I was then officially connected exhibited all his great powers of experimental skill, resource, and persistence. His persistence in research work was one of Threlfall's most marked characteristics. He never knew when he was beaten; he hated to acknowledge defeat in the laboratory. From a commercial point of view perhaps this was occasionally a fault, but on balance it must have paid hand over fist. When engaged on a problem, he would work long hours at night in his laboratory at home, tireless in the pursuit of his end. A remark in his paper on "The Electrolysis of Molten Zinc Chloride" (*J. Soc. Chem. Ind.*, July 1929) indicates his constant attitude to research. After referring to the formidable experimental difficulties he would have to encounter, he says, "However, in the end I decided that such difficulties as might arise could probably be overcome by steady work and engineering". They were.

Threlfall afterwards referred to this work as his most complete and finished investigation. It occupied, on and off, a period of eleven years, but unfortunately its commercial application was first prevented by the War, and afterwards rendered inadvisable by reason of other developments. However, this commercial failure had its bright side for other people, for it set him free to publish an account of the work on the occasion of the award to him of the Gold Medal of the Society of Chemical Industry in 1929. The account is necessarily brief; but it is written clearly and forcefully, and gives the reader a good idea of the magnitude of the problem, and of the skill and wide knowledge of the investigator.

The details of most of Threlfall's industrial work must necessarily remain confidential, but a brief reference to the chief items will indicate its scope. In addition to his researches on the electrolysis of fused zinc chloride, he worked out processes for the electro-chemical production of sodium chlorate, and ammonium persulphate, which were successfully operated on a large scale. He was also responsible for the substantial improvement of electric furnaces for the production of white phosphorus,

and for the erection of a station at Oldbury for the generation of electricity on a large scale from gas-engines. In the course of some of this work he was led to investigate the flow of gases in pipes, an account of which he afterwards published. He also devised a characteristic method for determining the efficiency of electric generators by air calorimetry, which gave rise to considerable discussion and interest among electrical engineers at the time (1903). His remaining industrial work included the development of processes for the manufacture of carbon tetrachloride and carbon disulphide, the production of ferro-chrome, and of some of the rare metals.

In my view, which I feel sure will be shared by all who knew something of his work, Threlfall was one of the greatest of electro-chemists. It was a subject which exercised to the full his profound knowledge of physics, his practical acumen, and, on the industrial scale, his engineering instincts. It is unfortunate that he was never able to publish a book on the subject, for his great experience and firm grasp of the subject would have certainly provided a strong impulse for further scientific research, especially in the rather neglected field of the electrochemistry of fused salts. Published scientific knowledge on this subject is meagre compared with knowledge hidden away in the electro-chemical industry, and the industrial electro-chemist must derive little benefit from current scientific literature. Some remarks of Threlfall's in an address to the Birmingham Section of the Institution of Electrical Engineers in 1905 are worth quoting. "The most pressing want at the moment among laboratory electro-chemists is a sense of humour in those who contribute accounts of their work to the various journals. Many of these papers appear to have been written with the idea that people interested in the subject enjoy reading for its own sake, and actually prefer fifty pages to five. . . . It is a thousand pities that the subject of electro-chemistry owes so little to French chemists—had it been otherwise, we should no doubt have had a standard of exposition which would have reduced the volume of the literature in the ratio of, say, ten to one." Possibly some may think that these remarks are true to-day, and that they have an even wider application.

The War gave Threlfall an opportunity of giving his great knowledge and experience to his country, and incidentally benefited him by widening his interests and giving him greater scope for his powers. In his own words, he was beginning in 1914 to settle down to the normal life of a successful business man in the Midlands, his only close touch with the scientific world being through the Royal Society, and its Dining Club, at the meetings of which he was a constant attendant. The War changed all that without bringing him the sorrows of a parent, for three sons, after long war service, all returned safely. Sir J. J. Thomson has already alluded to his valuable work for the fighting services; I need only add, as a matter worthy of special record, that he was the first to suggest the use of helium in balloons and airships, and expressed the opinion in 1915 that sufficient quantities of this gas could be found in the sources of natural gas in the United States.

Fresh opportunity for public service of the highest importance came with the formation of the Department of Scientific and Industrial Research in 1915. Threlfall was one of the original members of the Advisory Council, and remained a member until 1926. It would be no injustice to the other distinguished members of the Council during Threlfall's term of office to describe him as the hardest worked of any who had no direct responsibilities for the work of the research stations. The voluminous papers with which members of the Council were supplied to prepare them for the fortnightly meetings were scrupulously read through by Threlfall and marked copiously with his notes. His criticism could be trenchant, but was always constructive when possible, and seldom destructive without justice. His strong personality, his intense interest in the Department, and his sympathy with and understanding of all phases of the work, made him an invaluable member of the Council. He thoroughly enjoyed it all; he liked the fresh atmosphere, the opportunity of forming new friendships and renewing old ones, the feeling that he was useful and appreciated. The Department was fortunate indeed, in its formative years, to be able to command the services of one who was perhaps the most informed scientific man actively engaged in industry.

It was in the country that one got to know Threlfall best. A country squire himself by tradition and upbringing, he loved every phase of country life; one could not spend a day in the country with him without learning something fresh about Nature, and something, too, of the essential kindliness of the man. He was never happier than when by his beloved River Vyrnwy in North Wales, a long stretch of which he rented for fishing for more than twenty years. He liked to have his friends there, often depriving himself of his own fishing in order to put the expert visitor on to the best parts of the river, or to instruct the beginner. Indeed he overflowed with hospitality and geniality, loading his car with delicacies for his guests until, if boys were of the party, it looked like a travelling tuck-shop. Then there were the long evenings at the Wynnstay Hotel, Llanfyllin, when, after a hearty meal, and hearty laughter at good stories, and discourses on the art of fishing, he would sometimes talk of days gone by: of school days at Clifton and how he shared a study with Douglas Haig; of his classical education, which he thought was overdone ("I could never understand why so much importance is attached to the opinions of men who had access to so little information"); of early days with 'J. J.' at the Cavendish, and how he inoculated him with a lifelong passion for Rugby football; of his life in Australia as a youthful professor, and how he spotted Rutherford as a 'winner' within ten minutes of his entering his laboratory at Sydney on his way from New Zealand to Cambridge with an 1851 Exhibition; of Robert Louis Stevenson, who shut his bedroom windows in the

hottest month at Sydney because it was so cold compared with Samoa; of Ludwig Mond, Kelvin, Rayleigh, and a host of others; with sometimes a sigh for vanished youth—his strength was a byword at Cambridge in his day—but always a sturdy interest in life and work. A great man, the staunchest of friends, and a most lovable character.

H. T. T.

PROF. K. SUYEHIRO

PROF. KYOJI SUYEHIRO, director of the Earthquake Research Institute, Japan, died after a brief illness on April 9 (*Bull. Earthq. Res. Inst.*, 10, v, 1932). Suyehiro was born in Tokyo on Jan. 24, 1877, the second son of Mr. S. Suyehiro, a well-known writer and politician. In 1900 he finished his course on naval construction in the Imperial University of Tokyo, and two years later became assistant professor on that subject. In 1909 he travelled abroad, and on his return in 1911 was appointed titular professor in the University. In 1925 he founded the Earthquake Research Institute, of which he served as director until his death. He was also president of the Society of Naval Construction and of the Physico-Mathematical Society. Much of Suyehiro's work is connected with naval construction. In seismology, he studied and measured the oscillations of buildings, and last year he visited the United States in order to attend conferences on the influence of earthquake shocks on buildings. Not the least useful part of his work lay in the guidance and encouragement of his numerous students.

News and Views

Prof. J. E. Lennard-Jones

THE first occupant of the recently created John Humphrey Plummer chair of inorganic chemistry at Cambridge will be Prof. J. E. Lennard-Jones, of the University of Bristol. During his tenure of office at Bristol, first as reader in theoretical physics and later as professor and first holder of the Melville Wills chair in this subject in the Wills Physical Laboratory, Prof. Lennard-Jones has carried out a number of important investigations in the field of molecular physics. His earlier work on the forces between atoms in gases, and later, in crystals, was of fundamental importance and led him to the study of cohesion and other surface phenomena such as adsorption, as well as the structure of molecules in general. The results that he obtained attracted general attention and were particularly appreciated by physical chemists and metallurgists, both in Great Britain and abroad, because of the light that was thereby thrown upon some of the most fundamental problems of modern chemistry. The post to which Prof. Lennard-Jones has now been appointed affords special opportunities for the continuation of this co-operation between theoretical physicists and chemists, which in the past has been far less marked in Great Britain than on the Continent. On the other hand, the University of Bristol, with which he has been associated for seven years, suffers the loss of an original thinker, a brilliant expositor, and a capable administrator.

International Congress of Prehistoric and Protohistoric Sciences

THE first International Congress of Prehistoric and Protohistoric Sciences, held in London on Aug. 1–6, must be counted completely successful. Foreign visitors seemed thoroughly satisfied with the arrangements for their instruction and entertainment; while the whole-hearted manner in which British archæologists supported the meeting both by their attendance and by the contribution of papers, as well as the ready enthusiasm with which they entered into the discussion of mutually interesting problems with their colleagues from other countries, ensured that this new undertaking should at least be launched under favourable auspices. The number attending the Congress was approximately six hundred, and just under two hundred papers were accepted for reading—too large a number perhaps; but the careful arrangement of subdivisions and the classification of papers reduced the inconvenience of clashing to a minimum. A high standard was maintained; and a number of papers, to some of which we hope to refer at a later date, dealt with topics of great importance. Some communications from foreign visitors were perhaps of a more highly technical character than those to which a British audience is accustomed; but this was to be expected with a membership of which a considerable proportion was professional. It is only in Great Britain that that interesting and valued survival, the amateur as archæologist, flourishes to any appreciable extent.

SENSATION was not lacking at the Congress, as may be gathered from the accounts, which were somewhat exaggerated, in the daily Press. Among these was the announcement, a little premature, of the deposition of Oldoway man from his pride of place as the oldest specimen of *Homo sapiens*—for which the evidence appears elsewhere in our columns (see p. 237)—and the new conclusions relating to the Lloyd's skull, which Prof. Elliot Smith announced in his review of recent discoveries in human palæontology. Even his opening remarks gave his audience a surprise, for he stated that he had been asked by Dr. E. Dubois to announce his recent discovery of three femora of *Pithecanthropus* among the material he brought from Java in 1900, which support the classification of that type as a true genus, and by their form justify the epithet *erectus*. Prof. Elliot Smith, however, pointed to the possibility of a connexion with Ngandong man, to the recent discovery of which he also referred. In regard to the Lloyd's skull, he made the remarkable announcement that this is now to be regarded as by far the oldest known representative of *Homo sapiens*. Dr. Matthew Young has made a statistical comparison

of the fragment with the skulls of a number of medieval women from Glasgow, which also show the abnormality of a supra-occipital bone such as is present in the Lloyd's skull, and has found it in all essentials of the modern type; while Miss Garrod, after a re-examination of the stratigraphical and archæological evidence, has arrived at the conclusion that it is Mousterian, or even earlier.

Ancient Cave-Dwellers in Texas

FROM the point of view of the student of the ancient cultures of North America, the investigations which are now being carried out by the Smithsonian Institution of Washington in the south-western United States are at present by far the most interesting in American archæology. It would seem well within the bounds of probability that the Basket-Maker–Pueblo sequence will be amply documented at no very distant date, if researches continue to be prosecuted with the vigour and success of the last few years. The Smithsonian Institution now announces the successful result of an expedition, of which Mr. Frank M. Setzler was in charge, to Texas. This expedition has just returned to Washington after exploring seven caves spread over a wide area in the Big Band and Chisos mountain region of south-eastern Texas. A considerable amount of cultural material was found, which points to the caves having been the permanent habitation of a very primitive race of Indian, unfortunately without any indication of its affinities. It is possible that it may be related to the Basket-Makers of Arizona and New Mexico, who were partially cave-dwellers; but there are differences in culture, especially in the basketry and arrow-shaft techniques. The food of the Texan cave-dwellers appears to have been principally cactus, of which they chewed the pulp and spat out the fibre. This was supplemented by the flesh of bear, deer, rabbits, and birds of all kinds. Their clothing and baskets were woven of cactus fibre. The most remarkable custom, however, was that of burying the body of a small child, never more than two years old, in the exact centre of the caves which were their dwellings, a characteristic they shared with some of the ancient Mayas.

Research Management and Budgeting

To a symposium on the management of research, appearing in recent issues of *Industrial and Engineering Chemistry*, W. A. Hamor and G. D. Beal contribute a paper on the control of research expense (April 1932, p. 427). The recognition of the importance of planning and control in management, which has become widespread during the last ten years, has led to the administration of research being placed on a much more accurate basis. The progress in the control of research expenses made possible by systematic planning and budgeting has been to the joint advantage of management, technology, and science in that due attention can be given, in planning research, to the probability of the solution of a problem at a cost commensurate with its value. All research expense cannot, of course, be reduced to a method of accounting, but positive savings which can be classified should be accounted as such and duly credited against the improvement in process efficiency, reduction or disposal of wastes, patents, etc., the remaining research expense concerned with the maintenance of quality through control, improved, or novel products being charged off to product and market improvements.

AN accounting system will guard against the numerous uneconomical practices and wastes that can easily creep in and fritter away resources of time or material. Budgetary control is quite possible in spite of being based on estimates because it is not a substitute for management; and when reasonably close estimates have been prepared, the expenditure of the sum to the most advantage will largely depend upon the director. The methods of control adopted, while sufficiently elastic, should enable time and materials to be costed up against the laboratory investigation on which they have been expended, whether improvement of existing processes or products or the discovery of new products or processes, other expenses such as cleaning, light, heat, power, etc., being charged on a *pro rata* basis. In such budgeting and control, the question of salaries and increases of salary and travelling allowances will be considered from a broad point of view, calculated to encourage the development of scientific enthusiasm and the stimulus of contact with other professional workers at scientific meetings.

Volcanic Steam for Power Generation

ON July 22, Prince Ginori Conti gave a lecture to the International Union of Power Producers at the hall of the French Institution of Civil Engineers. The possibility of utilising the heat energy in the interior of the earth has frequently been considered by engineers, but in practice it is necessary that the heat be localised near the surface of the earth if this is to be done on a commercial basis. In Tuscany, not far from Florence, Prince Conti has an installation in a volcanic region where low pressure steam issues from cracks in the ground. A system of boring has recently been adopted to obtain the vapour at a higher pressure and increase its volume. The vapour is charged with sulphur, borax, and carbon dioxide. For many years borax has been obtained from the ground round the vent-holes, on which much of the vapour was condensed. Owing to the corrosive nature of the vapour, it was very difficult to design suitable apparatus. At one of the stations the steam generated in the boilers is used to supply suitable low pressure turbines. At another station high pressure steam is employed. Aluminium is used for the conductors in the stations, as copper corroded much too quickly. The total capacity exceeds 12,000 kilowatts, but there are several difficulties still to be overcome. The problem is simpler at Sonoma, in California, where the unwanted gases are easily eliminated from the vapour. The hot vapour is found at depths of between 100 and 200 yards. At present this station supplies 11,000 kw. to the surrounding district. According to *World Power* of July, there is a large quantity of power available in the volcanic regions of Bolivia.

B.D.H. Products

WE have received from the British Drug Houses, Ltd., London, N.1., copies of their catalogues of fine chemical products and micro-analytical reagents and organic reagents for 'spot' tests. The standards of purity adopted for chemical products are described in the B.D.H. book of A. R. Standards and those for pharmaceutical preparations in the book of P.P.P. (pure for pharmaceutical purposes) Standards. In the case of the latter, other considerations as well as purity must be taken into account, for example, ease of weighing for dispensing, and ready solubility with the formation of a clear bright solution. Low limits for lead and arsenic are defined, being in the case of most substances only a few parts (1 to 5) in a million. Other metallic impurities may not be physiologically harmful, but may cause precipitation, coloration, or some other reaction and so create difficulties in dispensing: their limits must therefore be fixed as well. The catalogues of fine chemicals run to nearly 150 pages and include lists of standard reagents, indicators, microscopic stains, and dyes. The same firm has also issued recently revised editions of booklets describing their vitamin A and vitamin D preparations, avoleum, radiostol, radiostoleum, and radio-malt. Advance in our knowledge in the vitamin field has been so rapid that frequent revision of brief summaries of this work is required. The activities of the products are controlled by physiological tests and standardised in terms of the international standards wherever such standards are available.

Treatment of Leprosy

DERIVATIVES of chaulmoogra and hydnocarpus oils now have an established position in the treatment of leprosy. The active constituents are certain fatty acids, which are usually administered as their soluble sodium salts or as the ethyl esters. A mixture of esters of the acids of the chaulmoogric series with 0·5 per cent iodine has been recently recommended for the intradermal treatment of the superficial lesions of the disease: the addition of the iodine reduces the irritating properties of the ethyl esters. The intradermal method is relatively free from general and local reactions: rapid resolution of the raised macules, infiltrations, and nodules is reported when small amounts of the solution of esters and iodine are injected into the skin around them. Messrs. Burroughs, Wellcome and Co., London, have issued a solution of these esters with 0·5 per cent iodine, suitable for intradermal and intramuscular administration, under the name "Iodised Moogrol". It is recommended that 5 c.c. be given at weekly intervals: the intradermal injection should be 0·1 c.c. at each point. Intradermal administration should be combined with intramuscular, part of the dose being given by each route.

Oceanography of the Baffin Bay Region

THE United States Coastguard in 1928 sent an expedition in the ship *Marion* into Davis Strait and Baffin Bay to carry out scientific investigations connected with the international ice patrol, particularly in regard to ocean currents, ocean depths, and ice conditions in the region north of that usually covered by the ice-patrol vessels each spring and summer. The ship followed a zigzag track northward from the Gulf of St. Lawrence to and fro between Labrador, Greenland, and Baffin Island. An account of the expedition and its results are being issued as the U.S. Coastguard *Bulletin* 19, published in three parts. Part 1 (Washington: Government Printing Office, 1932; pp. 81, 50 c.), just issued, contains a fascinating narrative of the cruise, illustrated by 38 well reproduced photographs; it gives also a report and discussion of the sounding work accomplished (by the echo method), and a description and discussion of the bottom samples obtained at some of the places where wire soundings were made. Part 3, published last year, dealt with the arctic ice and its drift into the North Atlantic Ocean, while Part 2, to be issued shortly, will report on the oceanography of Baffin Bay and Davis Strait.

Physiography of the Nile Basin

IN recent years a great deal of information on the Nile basin, the regime of the Nile, and the control of its floods has been collected by the Irrigation and Physical Department of the Egyptian Ministry of Public Works. This has resulted in a series of valuable papers, including the volumes on the Lake Plateau Basin of the Nile published in 1925 and 1927. This work continues and is being correlated with meteorological and hydrographical work in Uganda and other parts of East Africa. The Irrigation and Physical Department has now published the first of a new series of volumes on the Nile ("The Nile Basin." H. E. Hurst and P. Phillips. Physical Dept. Paper 26. Cairo, 1931. P.T.50). It deals particularly with the topography of the Lake Plateau, Bahr-el-Jebal, Bahr-el-Ghazel, Sobat basin, and White Nile basin, with a full account of the meteorology of the whole basin. A feature of the book is the large number of coloured folding maps, including maps of the whole basin on a scale of 1 to 2,000,000. There are also numerous climatic maps and many excellent illustrations. The volume concludes with a long bibliography of the Nile.

Plains of Southern Alberta

A REGION embracing such well-known names to the petroleum technologist as Calgary, Turner Valley, Bow Island, and Medicine Hat, will always preserve a certain freshness, but more because of its oil and gas industry than on account of any special geological merit. Yet the Alberta Society of Petroleum Geologists has made much lately of its stratigraphy and palæontology, and publications concerning these aspects of research have not been by any means restricted. As is often the case where a sense of vastness seems to engulf human effort, so in the Southern Plains has much of the significance of disconnected work been lost to the wider fraternity of geologists. The Donaldson Bogart Dowling Memorial Symposium on this stratigraphy (Tulsa, Oklahoma: Amer. Assoc. of Pet. Geol.; London: T. Murby and Co. 3 dollars) is not only a happy thought to the memory of a

man who probably knew his "Plains" better than any other, but also a genuine effort at co-ordination and presentation of the results of carefully focused investigations. It might, however, have been substantially improved by a more complete summary of the present position of our knowledge, by way of introduction to the several contributions, than is attempted in the brief foreword; this, though sufficiently lucid so far as it goes, still leaves to the reader the task of fitting together the various pieces of evidence to make a pleasingly intelligent picture of the whole.

Index of Publications of the Royal Society

The Royal Society has issued in one alphabet an author index to its *Proceedings*, Series A and B, from 1905 to 1930, and to the *Philosophical Transactions*, Series A and B, from 1901 to the same year, the entries being arranged chronologically under each heading. A previous index to the *Proceedings* was published in 1913, which covered the period from 1800 (when the series began under the title "Abstracts of Papers printed in the Philosophical Transactions") to the year 1904, so that the author index to this publication is now complete to the year 1930. The only indexes to the *Philosophical Transactions* hitherto available have been author and subject indexes down to the year 1830, but the "Catalogue of Scientific Papers", which includes papers in the *Philosophical Transactions*, may be considered to continue the indexing under authors' names down to the year 1900, whence the new volume completes it to the year 1930. So far as the author index is concerned, therefore, the indexing of the two publications is available for their entire runs. A subject index from 1800 is still lacking, except in so far as the mathematical, mechanical, and physical papers for the period 1800–1900 are concerned, since these have been included in the three published subject indexes to the "Catalogue of Scientific Papers", which covers both publications.

Science and Letters in Poland

The principal contribution to vol. 15 of *Nauka Polska* (Polish Science), which has recently appeared, is Prof. Z. Szweykowski's account of the Institute for the Promotion of Science and Letters in Poland. This Institute, which is to-day under the patronage of Prof. I. Mościcki, the President of the Polish Republic, and himself a distinguished chemist, was founded in 1881 in difficult circumstances from the Mianowski Fund. It has had a chequered history, but the Mianowski Institute now occupies the spacious Staszic Palace, and its future is assured. The aim of this Institute is the furtherance of all branches of science in Poland. It has already published or supported financially the publication of 1200 volumes and the preparation of 200 scientific works, and has subsidised fifty scientific periodicals. In addition, it has made grants to some fifty societies, research laboratories, and museums. The same volume of *Nauka Polska* includes a comprehensive survey of the progress of science in Poland between 1800 and 1880 by Prof. F. Bujak. It constitutes a summary of the works of Polish men of science during the greater part of last century. Other articles deal with the present-day needs of applied physics, the position of the State libraries in Poland, and the scope and organisation of the Institute for Slavonic Studies.

Habits of Bats

In the *Journal of Mammalogy* for May (p. 133) Mr. C. E. Johnson gives some notes on a family of red bats (*Lasiurus borealis borealis*) in captivity, and mentions that the old female, when let loose indoors, alighted more than once on the floor, and rose as easily as a bird. In the eighteenth century, Gilbert White alludes to a tame bat he saw, which several times confuted the vulgar opinion that bats could not rise from a flat surface, by rising with great ease from the floor; and the writer of this note has found the common yellow bat of India (*Nycticejus kuhli*) and the collared fruit-bat of Africa (*Rousettus leachi*) also quite able to take wing from the flat. These examples are worth giving because the error mentioned by White still persists, and in quarters where 'vulgar opinion' might not be supposed to be the vogue. The fact is that a bat does not voluntarily remain on the flat in the open, but may no doubt be found there unable to rise owing to some incidental disability, just as a man may be found lying helpless on a pavement for a similar reason.

Safety in Mines

The Safety in Mines Research Board has recently issued its tenth Annual Report, which contains a good deal of matter of scientific interest. Perhaps the part that will be most widely read is Appendix No. 9, which refers to researches intended to obviate fatalities from falls of ground. It commences by a record of researches on the strength of supports, etc., carried out under the direction of Prof. S. M. Dixon, and, furthermore, contains summaries of the results obtained by the various district committees working on the subject throughout Great Britain. The body of the Report shows considerable activity on the part of the Board, and indicates how greatly the scope of the work has been extended and how much has been done to make the results accessible to mining men generally. It must, however, be admitted that the work so far has been rather of the nature of collecting scientific material which will, no doubt, be useful at some future date in increasing the safety of mining, for up to the present the results obtained are of scientific interest rather than of practical importance.

American Railway Progress

The issue of the *Journal of the Franklin Institute* for March contains the address of Mr. W. C. Dickerson, president of the American Locomotive Company, on the progress made during the interval 1920–30. The 15 charts reproduced allow it to be readily seen. The weight on the driving wheels of the goods locomotive has increased from 245 to 247 thousand pounds, but the drawbar pull, at 28 miles an hour, from 32 to 50 thousand. For the passenger locomotive the corresponding figures are 192 to 187 and 18 to 44 thousand

pounds, at 60 miles per hour. Engine runs have been increased from 140 to 400 miles, crews being changed at intervals. As a result there are fewer locomotives in use to-day than ten years ago. Goods waggons have increased in size and decreased in number, and ordinary passenger coaches have been replaced by Pullman cars. The ton miles for goods have risen from 410 to 447×10^9, but the passenger miles have fallen from 47 to 31×10^9. Revenue increased from 6·2 to $6{\cdot}3 \times 10^9$ and operating expenses decreased from 5·8 to $4{\cdot}5 \times 10^9$ dollars. Mr. Dickerson is not satisfied that 45 per cent of the locomotives in use are more than twenty years of age. He shows that it is in the end more economical to replace old locomotives rather than to rebuild them. He considers that the diesel-electric locomotive has a wide field of usefulness.

Smoke Abatement

THE *Quarterly Journal* of the National Smoke Abatement Society, issued by the Society, 23 King Street, Manchester, among other things analyses the progress of smoke abatement as revealed by the latest Report on Atmospheric Pollution issued by the Department of Scientific and Industrial Research. This records for the average of a number of stations a decrease in 'total deposits', in tar, and sulphate averaging 16 per cent, 24 per cent, and 19 per cent respectively. While this decrease may partly be due to industrial depression, it is concluded that there has been a definite reduction of domestic smoke. Some of the figures, if correct, suggest that current ideas require revision. While the atmosphere of industrial cities seems to be improving, conditions in London get worse, and now appear to be similar to those of Hunslet—an industrial area in Leeds. Again, the suburbs of Leeds yield figures better than those of Southport. Such comparisons will suggest the need for caution in interpretation, but the figures show that conditions can be improved, and the *Journal* does a good service in emphasising this.

Food Technology

REFERENCE has previously been made in these columns to the problems of food preservation and their importance to modern civilisation. The more scientific aspects of the subject are dealt with in the reports of the Food Investigation Board and the Empire Marketing Board, and references to the extensive literature on the subject can be found in the "Index to the Literature of Food Investigation". *Food Technology* is described as a monthly review of manufacture, packing, and transport for production managers, food chemists, and engineers, and is designed to make known the work of research centres and to secure greater publicity for their achievements. The journal contains articles on different aspects of the food trade, answers to readers' inquiries, and notes on recent patents, amongst other features. It appears that it should fulfil its object of keeping those engaged in modern food factories in touch with research work on the treatment of food, as well as with the necessary auxiliary trades. It is edited by Dr. H. D. Law, 153 Stratford High Street, London, E.15; price 12*s*. a year.

Best Books in 1930

UNDER the title "Best Books of 1930" a selected list of books published during that year has recently been issued by Mr. Alex. J. Philip, "Lodgewood", Gravesend, and Messrs. Simpkin Marshall, Ltd., London, E.C.4. The list is classified on the Dewey Decimal System and has been selected with the help of many authorities, institutions, and societies. The main headings of the classification include general, philosophy, metaphysics, religion, sociology, philology, science, arts, literature, and history, and these are subdivided into their various groups. About 2500 "Best Books" are thus classified for the year 1930. Such a list should prove useful as a work of reference, and should be an asset to all lending and reference libraries, as well as to departmental and institutional libraries. Nevertheless, we venture to suggest that since the comparative value of a book is often a matter of opinion, such a selected list cannot be expected to be anything other than a tentative guide to choice.

Announcements

THE Third International Congress of Cytology will be held in Cambridge at the end of August 1933. Further particulars will be published in due course.

MR. I. W. M. ARMSTRONG-BLACK has been appointed assistant agricultural chemist, Nyasaland (Colonial Agricultural Service).

A SHORT training course for curators and assistants has been arranged by the Museums Association to be held at Manchester on Sept. 27–30. The course will be devoted to the study of the technique and administration of science and art museums and galleries, and will include visits to the Manchester Museum at the University, the Manchester City Art Gallery and branches, the Whitworth Art Gallery, and the Royal Museum and Art Gallery, Salford. No fees will be charged for attendance. Applications for grants towards students' expenses in attending the course will be considered by the Committee and should be addressed to the Secretary, The Museums Association Short Training Course, Public Museum, Bootle.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant agricultural chemist in the Department of Agriculture and Horticulture at the University of Bristol—Agricultural Advisory Office, 22 Berkeley Square, Bristol (Aug. 20). A lecturer in mechanical engineering at the Municipal Technical College, Hull—The Director of Education, Education Offices, Guildhall, Hull (Aug. 20). A principal of the Lester Technical School and Institute, Shanghai—The Secretary, Association of Principals of Technical Institutions, Chelsea Polytechnic, Manresa Road, S.W.3 (Sept. 1). An attendant for the Departments of Botany and Zoology at the North of Scotland College of Agriculture—The Secretary, 41½ Union Street, Aberdeen. An assistant tobacco chemist in the Chemical Laboratories of the Ministry of Finance, Egypt—The Chief Inspecting Engineer, Egyptian Government, 41 Tothill Street, London, S.W.1.

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Artificial Disintegration by Neutrons

FOLLOWING up the experiments already reported,[1] I have recently taken 1490 pairs of photographs of the tracks produced in an expansion chamber filled with oxygen (97 per cent by volume) when a source of polonium and beryllium was placed in the centre. The conditions of experiment and the source itself were the same as in the previous work, the initial pressure of the gas being roughly atmospheric.

About sixty recoil tracks were obtained and, in addition, seven or eight examples of paired tracks, providing certain evidence of disintegration. These numbers may be compared with about a hundred recoil tracks and thirty disintegration pairs recorded in the nitrogen photographs (1740 in number). It appears, therefore, that the disintegration probability for neutron-oxygen nucleus encounters, though doubtless somewhat smaller, is yet of the same order of magnitude as that which characterises similar encounters with nitrogen nuclei. This is in itself an interesting result, for hitherto no certain evidence has been obtained for the artificial disintegration of oxygen —either by α-particles or protons.[2]

The disintegration photographs have been examined and measured by the stereo-reprojection method previously employed. It appears likely that in all cases so far observed, disintegration has occurred with capture of the incident neutron. If that be accepted, then the disintegration particle is almost certainly an α-particle. The nuclear reaction may be written

$$O^{16} + n^1 \longrightarrow C^{13} + He^4.$$

(From momentum relations alone it is practically impossible to distinguish this process from that in which the resulting nuclei are C^{12} and He^5, but for the present this latter possibility may be passed over.) In the accompanying table, E, the kinetic energy of the responsible neutron, and W, the energy absorbed in the disintegration process, are given as deduced for the eight cases observed. The energy unit employed is 10^6 electron volts.

No.	1	2	3	4	5	6	7	8
E	7·0	7·0	6·2	7·6	4·2	5–7	4–7	2·2
W	2·2	4·3	3·5	5·2	1·7	1·0	2·5	1·2

Numbers 1 to 4 may be regarded as satisfactory, with a probable error of $0·5–0·7 \times 10^6$ e.v., numbers 5 to 7 carry somewhat less weight, and number 8 is rather doubtful.

The results as a whole, however, show that the capture disintegration in question takes place with the absorption of energy, the amount absorbed being different on different occasions. This probably means that in some cases the nucleus C^{13} is left temporarily in an excited state, afterwards emitting a quantum of γ-radiation in its return to the normal. Now, this nucleus is also produced in the artificial disintegration of boron by α-particles, and the existence of proton groups having an energy separation of 3×10^6 e.v. and of the accompanying γ-rays are established facts.[3] Some such energy difference as this is consistent with the values of W given above.

The neutron energies given in the table are in general somewhat greater than those deduced in most of the cases of capture disintegration in nitrogen. The energies deduced from recoil track measurements, on the other hand, were in complete accord with the nitrogen results. It is possible that the smaller disintegration yield in oxygen is the necessary consequence of the greater mean energy required for disintegration; moreover, the present results confirm the suggestion that a small fraction of the radiation from beryllium is of higher energy than was previously believed to be the case. This suggestion was first made by Curie, Joliot, and Savel from other considerations.[4] We may conclude, in fact, that the upper limit of energy of $6·4 \times 10^6$ e.v. previously obtained is appreciably too low.

The experiments here described are being continued with oxygen at greater dilution, in the hope of increasing the accuracy of measurement and further investigating the disintegration phenomena which occur.

N. FEATHER.

Cavendish Laboratory,
Cambridge, July 28.

The Oldoway Human Skeleton

DR. L. S. B. LEAKEY's claim that the Oldoway man of *Homo sapiens* type was buried in Bed 2 of his succession, before the formation of the overlying Beds 3 and 5, rests on his statement that no material from Beds 3 and 5 was found in intimate association with the skeleton in the burial, although such material is found lying on the present surface-slopes of the gorge at and near the site.[1]

On discussing the matter with Prof. D. M. S. Watson and Mr. A. T. Hopwood, I came to the conclusion that more thorough investigation of this critical evidence was desirable, especially as subsequent alteration of rock-material in the neighbourhood of the skeleton might have rendered it less easily recognisable than in its unaltered condition. I therefore suggested that the deposits of Beds 2, 3, 4, and 5, as well as the material found within the ribs of the skeleton, should be carefully re-examined. Mr. Hopwood kindly supplied typical samples of Beds 2, 3, 4, and 5 collected by him at Oldoway. The petrological investigation of the deposits was undertaken at the Imperial College by Dr. J. D. Solomon, who had formerly worked with Dr. Leakey in East Africa and was familiar with the occurrence of similar beds in the field. Dr. Solomon found that each of the deposits possessed distinctive lithological and mineralogical characters. The way now being clear for a useful examination of the grave-contents, Prof. Reck, at Mr. Hopwood's request, persuaded Prof. Th. Mollison of Munich to send us a sample of material which, he assures us, was part "of the material in which the Oldoway skeleton had been embedded". Dr. Solomon, Mr. Hopwood, and I together examined this material. It contains (*a*) pea-sized bright-red pebbles like those of Bed 3, and (*b*) chips of concretionary limestone indistinguishable from that of Bed 5 and enclosing at least one mineral (an amphibole), in relative abundance, not found in Beds 2 and 3, but present in Bed 4.

Assuming, therefore, that the provenance of the materials supplied to us is as stated (and we have no reason to doubt it), the Oldoway interment is not contemporaneous with Bed 2 containing Chellean-

Acheulean implements, but was made after the formation of the concretionary limestone ('steppe-lime') of Bed 5, that is, is post-Aurignacian.

The samples are being kept for reference in the British Museum (Natural History), South Kensington.

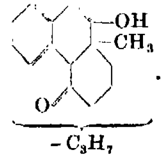
Chemical Constitution of the Follicular and Testicular Hormones

Follicular Hormone

IN a paper published recently by Butenandt and his co-workers,[1] the hypothetical formula (I) was developed for the follicle hormone.



. . . . . (I)

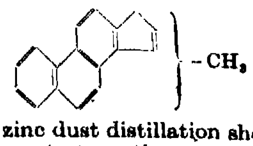
This formula attempted to correlate the X-ray measurements of J. D. Bernal,[2] which made a three-ring system for the hormone probable, with the chemical evidence at that time in hand.

A series of new experiments up to the present have not substantiated formula I, but indicate that in the hormone molecule there are only three aromatic double bonds (a benzene ring) present, that is to say, four rings altogether.

(1) Even by most energetic catalytic hydrogenation, only three double bonds are saturated in the hormone and hormone hydrate molecule. The following derivatives were prepared: Hexa-hydro-hormone-hydrate $C_{18}H_{27}$ $(OH)_3$ (F.P. 256°), Hexa-hydro-desoxy-hormone-hydrate $C_{18}H_{28}-(OH)_2$ (F.P. 153°), Hexa-hydro-desoxo-hormone $C_{18}H_{29}.OH$ (F.P. 105°). All three alcohols react as completely saturated substances. The hexa-hydro-hormone-hydrate, which was the product most fully investigated, is completely stable towards potassium permanganate, perbenzoic acid, and ozone. As in the case of the other alcohols, it gives no reaction with tetranitromethane.

(2) Careful *molecular refraction measurements* of the hormone hydrate, its acetate, and its methyl ether, as well as of the desoxo-follicle hormone, $C_{18}H_{23}.OH$ (F.P. 133°), give values which completely agree among themselves, and are only compatible with a hormone formula containing three isolated double bonds or one benzene ring. These results are of especial interest, because hormone formula (I) demands increments not only for four double bonds, but also a marked exaltation due to the conjugation of the enolic double bond to the benzene ring.

(3) *Attempts at dehydrogenation* with electrolytic zinc dust produced an aromatic hydrocarbon (F.P. 234°), which is perfectly stable towards potassium permanganate, and, according to the analyses and molecular weight determinations to date, has the formula either $C_{18}H_{14}$ or $C_{17}H_{14}$. This formula points to the existence of four rings (for example, three benzene rings and one five-membered ring).



. . . (II)

Inasmuch as a zinc dust distillation should be applied only with the greatest caution to a structural determination, these results are given only as contributory evidence pointing to the existence of a four-ring structure in the hormone molecule.

The discrepancies of these results with the measurements of Bernal[2] and with the 'enolic nature' of one of the three aromatic double bonds[3] must be fully investigated before a decision can be reached regarding the basic skeletal system.[4] The similarity of formula II to the new formula recently suggested by Wieland and Windaus[5] for the sterols, bile acids, and pregnandiol, indicates the possibility that the hormone is closely related to these compounds.

Testicular Hormone

During the past year, four different crystalline products have been isolated from the oily fraction of human male urine which is highly active in the cock's comb test as well as on the vesicular glands of rodents.[6] These products are at present being investigated. The tentative results, which have been carried out on extremely small amounts of substance, give the following picture, the details of which must all be confirmed:

(1) Substance, $C_{18}H_{28}.(OH)_2$, F.P. 232°, isomeric with hexa-hydro-desoxy-follicle-hormone-hydrate; $\alpha = +16.6°$; acetate F.P. 112°.

(2) Oxy-ketone, $C_{18}H_{30}O_2$ or $C_{17}H_{28}O_2$, F.P. 163°, $\alpha_D = +76°$, oxime F.P. 216°.

(3) Oxy-ketone, $C_{16}H_{26}O_2$ (?), F.P. 176·5°, $\alpha_D = +89.9°$, acetate F.P. 158°, oxime F.P. 215°.

(4) Oxy-ketone, $C_{16}H_{26}O_2$ (?), F.P. 178°, acetate F.P. 160°.

Only the last-mentioned oxy-ketone, F.P. 178°, produces high physiological activity in the smallest doses in the capon test, and is to be considered as the hormone producing comb growth. A total of 1-1·2 γ given in four doses within two days produces a growth effect up to 30-35 per cent in the area.

The remaining crystalline products appear to be completely inactive as regards growth of the comb when they are absolutely pure, even in doses 600 times as strong (detectable activity in the larger doses might be due to traces of the hormone). The physiological activity of the crystals on the genital tract of rodents is at present being investigated.

Gill-Morrell and Barkhausen-Kurz Oscillations

MR. R. COCKBURN has shown that with one vacuum tube he obtained by means of the Barkhausen-Kurz method electromagnetic oscillations of two kinds.[1] These oscillations differed one from the other by the dependence of their wave-length on the length of the oscillating circuit connected with the tube. One of these oscillations he referred to as the *GM*-type and to the other one as the *BK*-type.

The oscillations with similar dependence of the wave-lengths on the length of oscillating circuits as described by Mr. Cockburn were obtained by us several times with different vacuum tubes. These oscillations we obtained by means of a generator of our usual construction[2] which had oscillating circuits in the plate and in the grid circuits of the tube. The oscillations obtained by us, and similar to those referred to by Mr. Cockburn as the *GM*-type, corre-

sponded to those parts of the regions of oscillations of the 'working diagrams' of the tubes[3] for which the grid potential E_g was near to the potential E_s of the upper bend of the statical $I_s E_g$-characteristics of the tube. The oscillations similar to those referred to by him as the *BK*-type corresponded to the same regions of oscillations but to potentials $E_g > E_s$. Fig. 1 confirms this, showing the dependence of the wave-lengths of the oscillations on the length of the plate and grid circuits. These latter were always in resonance with each other. The measurements were performed with a constant heating current and at constant grid potentials.

It is seen from Fig. 1 that the oscillations corresponding to $E_g = 100$ v., 120 v., and 150 v. ($> E_s$) do really differ from the oscillations corresponding to $E_g = 50$ v. ($< E_s$). The wave-lengths of the former depend on the length of the oscillating circuits rather less than the wave-lengths of the latter. In spite of this difference, it is impossible to refer to one of these oscillations as the *BK*-type and to the other as the *GM*-type.

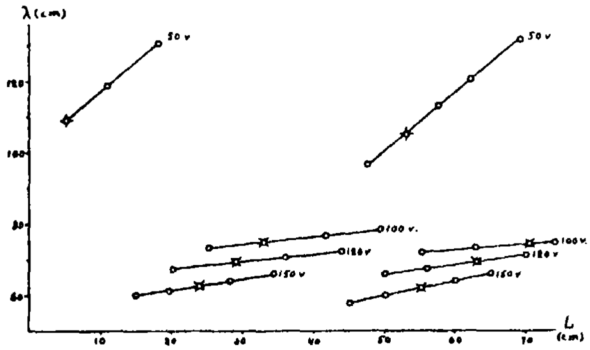

FIG. 1.—The dependence of the wave-lengths λ on the length L of the oscillating circuits; ⌘ the observations corresponding to the maximum of the energy of the oscillations.

With full confidence, all of them could be referred to as one and the same type of *GM*-oscillations. The greater dependence of the wave-lengths on the length of the oscillating circuits at $E_g < E_s$ is due to the fact that these potentials are limiting, that is, further decrease of E_g causes a cessation of the oscillations. Because of this, the oscillating 'regime' at $E_g < E_s$ is less stable than at $E_g > E_s$, and all external factors, including the variation of the length of the oscillating circuits, produce a greater influence on wave-lengths.

The results of Mr. Cockburn's investigations, as it seems to us, also do not give grounds to refer to the oscillations described by him as different types. In any case, no one of these oscillations can be referred to as the *BK*-type, because all of these are dependent more or less on the length of the oscillating circuits. Such a dependence cannot exist in the case of *BK*-oscillations. Unfortunately, using Mr. Cockburn's measurements, one cannot show with confidence the cause of the difference between the two oscillations described by him. This is due to the fact that during the observations he changed simultaneously the emission current and the length of the oscillating circuits. But, as is well known, the wave-length depends on both of them. It seems to us therefore very desirable that the conditions of observations should be changed in the future in such a manner that the dependence of the wave-lengths on the emission current and on the length of the oscillating circuits may be investigated separately.

In connexion with Mr. E. C. Megaw's letter,[4] we should like to point out that in our opinion the rôle of the space charges in the process of the generation of the *GM*-oscillations is rather limited, at least in the modern gas-free tubes. The generation of such oscillations is defined by the fulfilment of the conditions[5]

$$T = \tau, \frac{\tau}{2}, \frac{\tau}{3}, \ldots \qquad (M)$$

where T is the natural period (fundamental or overtone) of the oscillating circuit in which the oscillations arise and τ *is the time necessary for the electrons to* pass from the filament to the plate and back to the filament. In the case of tubes with close mesh grid, τ is a shorter time, since in this case the electrons will go from the filament to the plate and back to the grid only.[6] The condition $T = \tau$ corresponds to the 'normal waves', and the conditions $T = \tau/2$, $\tau/3$, ... correspond to the 'dwarf waves', that is, waves of higher orders.[7] In the case of a fulfilment of one of the conditions (M) the tubes can transmit energy into the corresponding oscillating circuit and can maintain their oscillations. The rôle of the space charges generally is to influence the time τ of the passage of the electrons. In rare cases, when the natural period of the space charges[8] will coincide with T and τ or with T and $\tau/2$, $\tau/3$, ... the intensity of oscillations must increase considerably. The oscillations described by G. Breit, H. Hornung, and by W. H. Moore[9] must be referred to these cases.

[6] H. E. Hollmann, *Ann. Physik*, **86**, 129-188; 1928.
[7] We avoid calling the 'dwarf waves' 'harmonics' or 'overtones' for the reason that they are not such in a usual meaning of these words, because they are generated completely independently of the 'normal waves'. In several cases, for example in absence of a suitable oscillating circuit, the 'normal waves' can generally be absent, but that does not preclude the generation of the 'dwarf waves'. The 'dwarf waves' have also a different character of dependence on the heating current from the 'normal waves' (see *Phys. Rev.*, **39**, 542; 1932). Because of all this, the similarity between the conditions (*M*) and the series of harmonical overtones is purely superficial.
[8] Concerning the natural period of the space charges see Th. V. Ionescu, *C.R.*, **193**, 515-577; 1931; and A. Rostagni, *Atti della R. Ac. di Torino*, **16**, 123-130, 217-223, 383-395; 1931. These authors place more importance on the rôle of space charges in the process of generation than we do.

Heats of Dissociation and the Periodic Law

LOTHAR MEYER's curves illustrating the periodicity of the physical properties of the elements are capable of extension to the heats of dissociation of simple compounds, not merely in the same group, but also in the same period. While interpreting results obtained by the examination of the infra-red spectra of triatomic molecules, Mr. A. B. D. Cassie and myself were able to show that a direct ratio exists between the heats of dissociation of certain related molecules and the force constants for the bonds concerned.[1] Two illustrations are given in the following table:

Molecule.	$K \times 10^{-5}$ dynes/cm.	*H.D.* kcal.	*K* ratio.	*H.D.* ratio.
CO	18·8	237	—	—
$\frac{1}{2}CO_2$	14·2	182	13·2	13·1
CS	8·4	158	—	—
$\frac{1}{2}CS_2$	6·9	132	1·2	1·2

Henri, from the extrapolation of the ultra-violet band spectrum of CS, had previously obtained the value of 193 kcal. for the heat of dissociation of this molecule; since the publication of our paper, he has shown that this value represents dissociation into a

normal C atom and an excited (^1D) S atom. Similarly he has determined from his own experimental results a heat of dissociation for SO of 148 kcal. and regards this as giving normal S and O atoms. Since the heat of dissociation of the oxygen molecule is only 118 kcal., the experimental value for SO is evidently too great. We have shown that the force constant for SO_2 is $9 \cdot 6 \times 10^5$ dynes/cm., and for SO is $7 \cdot 8 \times 10^5$ dynes/cm.; since the heat of dissociation of each SO_2 bond is 248/2, the corresponding quantity for SO should, from the above, be approximately $124 \times 7 \cdot 8 / 9 \cdot 6 = 101$ kcal., and hence the experimental value again represents dissociation into one normal and one excited atom, possibly in this case a (^1D) O atom.

It was further observed that the force constants for the molecules CO, NO, OO were proportional to the heats of linking for these substances; the periodicity thus observed suggested the calculation from band spectra data of the heats of linking of a large number of non-polar compounds of the second and third

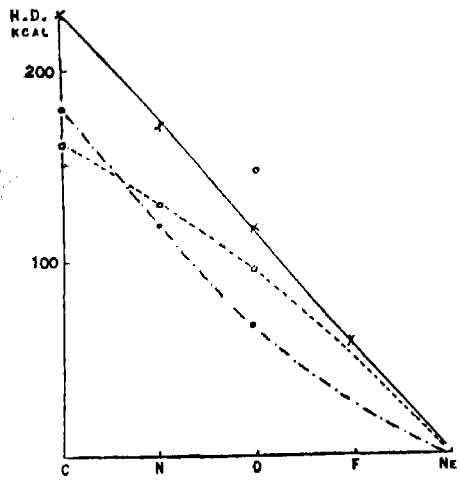

FIG. 1.—Heats of decomposition in second period. -x- oxide, -o- sulphide, -●- dioxides/2.

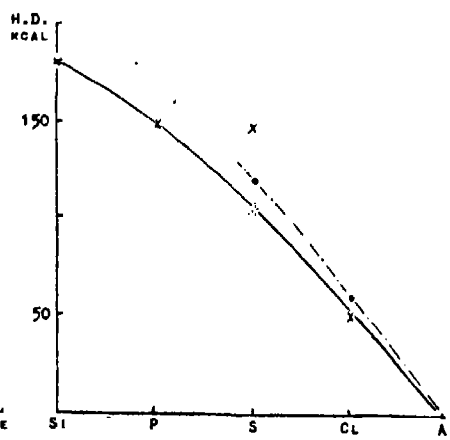

Fig. 2.—Heats of decomposition in third period. -x- oxides, -●- dioxides/2.

periods of the table: many of these, such, for example, as NS, have become only very recently available. Some of the data are given in Figs. 1 and 2, and it will be seen that the values lie on regular curves which are very nearly straight lines, the heat of formation of the inactive gas compound being taken as zero. If SO is taken either as the sulphide of oxygen in the second period or as the oxide of sulphur in the third period, it will be seen that the previously accepted value lies high above the curve in each case, interpolation giving the calculated value of *c.* 100 kcal. The method has been extended to the diatomic molecules of the elements and the nitrogen and carbon compounds; the regular nature of the curve holds in all cases. A number of interesting consequences arise and will be expounded in a subsequent paper: it will suffice to mention two of them, taken from the nitrides of the second period: (1) the experimental value for CN lies some 1·6 volts below the curve, suggesting decomposition into normal N and C atoms, C (^3P) being below C (^5S) by this amount; and (2) half the heat of formation of N_2O lies midway between NN and ON, confirming the structure NNO and not NON for this substance.

Micro-Analysis of Gases

KROGH'S micro-analysis method as originally described,[1] for small bubbles of from 50 to 100 cubic millimetres and containing oxygen, carbon dioxide, and nitrogen, is limited to bubbles which have been in contact with a fluid, because the lower cup of the micro-apparatus must be filled with some of the same fluid with which the gas bubble has been in equilibrium, otherwise the gas bubble will lose some gas, particularly carbon dioxide, which is so soluble in most fluids.

I have been attempting to modify this method so that gas tensions in any small bubble from an animal's tissues may be estimated, that is, also in bubbles which have not been in contact with excess of fluid. The problem was investigated using a freshly prepared solution of 80 per cent glycerol and 20 per cent distilled water to fill the cup, capillary, etc., of the micro-apparatus. The coefficient of solubility of nitrogen in glycerol is too low for measurement, and those for oxygen and carbon dioxide are too low to cause any appreciable absorption under the present conditions. The addition of the small amount of water to the glycerol enables the bubble to be moved up and down easily in the graduated capillary of the apparatus without breaking up.

A small gas bubble is injected anywhere in the body cavities, tubes, or tissues and after some hours' interval it is withdrawn by means of a standard 1 c.c. syringe fitted with a very fine needle, the dead-space of which is filled with the above glycerol solution. The bubble is then carefully transferred to the cup of the apparatus, which has been previously filled with the same solution. The remainder of the technique for analysis of carbon dioxide and oxygen is as described by Krogh. I have been able to analyse mixtures, of from 0 to 15 per cent carbon dioxide and from 0 to 20 per cent oxygen with the remainder nitrogen, in gas bubbles (50-100 c.mm.) using the micro-apparatus in this way; the gas tensions obtained agree, within 2-3 mm. Hg, with those obtained from analyses of 10 c.c. of gas in the ordinary Haldane analyser. Carbon dioxide and oxygen tensions in the bladder and uterus have been estimated with the above accuracy using this modification of the micro-method.

I have diminished the risk of entry of small bubbles of outside air into the lower cup during the manipulations by attaching a glass tube 8 cm. in length to its lower end by means of a short piece of rubber tubing. The lower end of the glass tube is bent slightly, and its opening is so cut that the under edge projects beyond the upper; the whole tube is kept filled with the same fluids as used for the lower cup.

Raman Spectrum and Molecular Structure of Ozone

AN attempt has been made to find the Raman spectrum of ozone, using a 30 per cent solution of ozone in liquid oxygen and a mercury arc as the exciting light. The solution is a dark purple in colour and absorbs the mercury line at 4358 A. quite considerably. The mercury line at 4046 A., however, is scattered fairly strongly, but it has no strong Raman companions. There is an extremely weak doublet corresponding to a mean frequency shift of 1280 cm.$^{-1}$, but no other Raman lines could be observed even with exposures lasting 80 hours. The spectrograph used was not particularly fast, but photographs of the weak oxygen line at 1550 cm.$^{-1}$ from 4046 A. could be obtained in 10 hours.

The conventional representation of the ozone molecule is an arrangement of the oxygen atoms at the corners of an equilateral triangle. More recently a straight line model has been proposed.[1] The weakness of the Raman spectrum is important as evidence against any simple symmetrical structure of the ozone molecule. On Placzek's theory,[2] either of these models would give rise to at least one strong Raman line, since each has a symmetrical mode of vibration in which the polarisability varies sharply with changes in the associated normal co-ordinate. The conclusion that the form of the ozone molecule is triangular but not equilateral is supported by the results of investigations of the infra-red absorption bands of gaseous ozone under high dispersion which one of us (S. L. G.) is carrying on at present.

A full account of the latter investigations, along with a discussion of the form of the ozone molecule, will be published later.

Post-Dissociation Radiation from Sulphur Trioxide

ACCORDING to Franck's theory of photodissociation of the halogens, the effect of light absorption is to split I_2 into a normal iodine ($^2P_{\frac{3}{2}}$) and an excited iodine ($^2P_{\frac{1}{2}}$). No direct proof has yet been forthcoming that the metastable atoms are actually produced in the reaction.

A direct proof of the production of the $^2P_{\frac{1}{2}}$-atoms may be attempted in various ways. The most convincing proof will be afforded if it can be shown that the illuminated I_2 vapour gives out radiations of frequency $\nu = {}^2P_{\frac{3}{2}} - {}^2P_{\frac{1}{2}}$ at very low pressures. The low pressure would avoid collisions of the second kind, and thus the energy of excitation would be available again as a radiation. The experiment with I_2 would be difficult, as the line $\nu = {}^2P_{\frac{3}{2}} - {}^2P_{\frac{1}{2}}$ would be in the far infra-red. But there is promise of better success with photodissociation of SO_3.

It was recently postulated by me[1] that SO_3, on absorption of light of wave-length less than λ2300 A., decomposes into SO_2 and O ($^1D_2$). If the assumptions are correct, it would mean that by irradiating SO_3 with light of wave-length below λ2300, we would obtain oxygen atoms in the $^1D_2$-state. If we prevent collisions of the second kind by sufficiently lowering the pressure, the forbidden transition line of the oxygen atom O ($^3P_1 - {}^1D_2$), corresponding to the wave-length λ6364, would be expected from the SO_3 gas.[2]

After repeated trials a weak line has been obtained by illuminating for 50 hours a 100 cm. long column of SO_3 gas at a pressure of less than 1 mm. The illuminating source was the condensed spark lines of cadmium below λ2300. The wave-length of the observed line is the same as that of the O ($^3P_1 - {}^1D_2$) line, that is, λ6364.

A New Photoelectric Phenomenon

METAL films are subjected to the passage of electric current and exposed to light, which is interrupted with acoustic frequency by a rotating disc with holes. A thermionic amplifier permits a sound of the same frequency to be heard in a telephone when silver, gold, platinum, and tin are tested: aluminium and zinc give no effect.

A copper wheel with sinusoidal border, carrying as many teeth as the holes of the disc, turns jointly with it. Against the border of the wheel, a jet of mercury is directed, the length of which pulsates with the same period as the light. The jet is included in the circuit of the metal film. By regulating the position of the jet and the resistances of the circuit, the sound at the telephone may be extinguished. It may, therefore, be concluded that:

1. The metals examined *increase* in resistance under action of the light. For silver, the maximum effect seems to be obtained in the ultra-violet region; for the other elements, such a maximum is displaced towards the visible spectrum and perhaps the infra-red.
2. The increase in resistance is of the order of 1/10,000 to 1/100,000 of the resistance of the metal.

The same experiments have been repeated by plunging the metal films into a current of water, but no sensible variation in the intensity of the effect has been noted. The effect appears, therefore, to result from direct action of light on electrical conductivity.

Origin of the Coronal Lines

IN a recent communication in these columns, Frerichs[1] has criticised de Bruin's classification of the strongest visible lines of the corona. In the same issue of NATURE, Dingle[2] also has criticised the identification of these lines. In each of these communications the authors failed to direct attention to another very strong objection to de Bruin's conclusion that the green auroral line and the green coronal line originate on the same metastable level of oxygen, the $^1S_0$ level. Since no trace of the green auroral line has ever been observed in the corona, and as no one has ever observed the green coronal line in either the aurora or in laboratory discharges in which the green auroral line was very intense, it is extremely difficult to see how the two lines can originate on the same initial state. If the two lines did originate on the same initial state, their relative intensities should be the same in both the aurora and the corona spectra. One might be able to account for a slight difference in relative intensities by postulating reabsorption of one of the lines, but it seems impossible to explain the profound difference which would follow from de Bruin's classification of the green coronal line.

Sex-Differences in Crossing-over and Chiasma-Frequency in the Mouse

HALDANE (1922) stated the law, based on the observations of many researchers, that if crossing-over is reduced or entirely suppressed, this occurs in the heterozygous sex. Reduction of crossing-over in the heterogametic sex is found in the Tettigidæ, *Gammarus*, *Mus musculus*, and *Mus norvegicus*, and complete suppression of crossing-over in the male of the Drosophilæ and in the heterogametic female of *Bombyx*.

Recent investigations on meiosis in diploids and polyploids have dispelled many difficulties and have increased our understanding of genetical segregation. Darlington (1930), adopting Janssens' (1924) partial chiasmatype hypothesis, states that "a chiasma is constituted by genetical crossing over between two of the four chromatids taking part in it, and association at diplotene is between chromatids derived from the same chromosome". Here Darlington is in direct opposition to the 'classical' theory held by Wenrich (1917), Wilson (1925), Sax (1930) *et alii*. Darlington's view assumes a close parallelism between chiasma formation and crossing-over. One important theoretical objection to Darlington's hypothesis, as he himself stated (1931), was that "the difference in crossing-over between the sexes has not been paralleled by the direct observation of differences in chiasma formation".

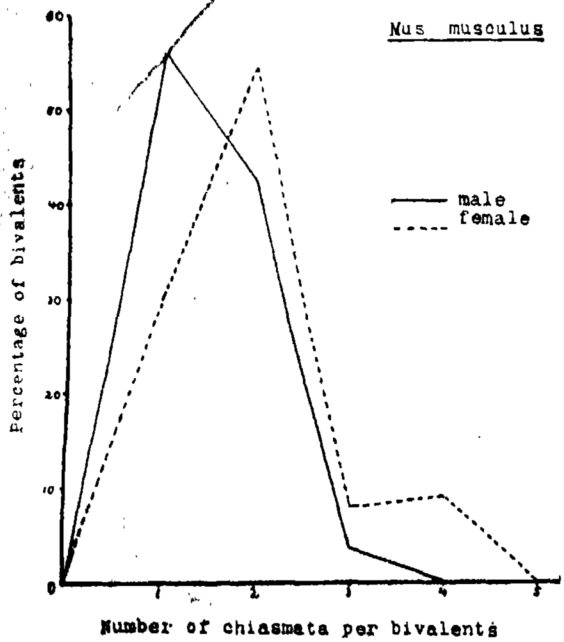

FIG. 1.—Graph illustrating the chiasma frequency of male and female *Mus musculus* at metaphase.

It was thought desirable to examine chiasma frequency in male and female mice, in view of the fact that it has been shown that linkage between the albino and pink-eye factors in *Mus* is closer in the heterogametic male, that is, the crossing-over value is lower in this sex than in the female. From these genetical data a difference in the chiasma frequency in the two sexes would be predicted on the chiasma-type hypothesis, whereas if any correlation between differences in chiasma frequencies and crossing-over values is to be expected on the alternative hypothesis that crossing-over is caused by the breaking of chiasma, the sex with increased crossing-over should have a reduced chiasma frequency.

Observations on chromosome behaviour during meiosis in *Mus* have revealed differences in the chiasma frequencies and terminalisation coefficients in the two sexes. In the female at metaphase the chiasma fre-

CROSSING-OVER VALUES BETWEEN ALBINISM AND PINK-EYE IN *Mus musculus*

CHIASMA FREQUENCY AND TERMINALISATION COEFFICIENTS DURING FIRST METAPHASE IN *Mus musculus*

	Total No. of Bivalents.	Total No. of Chiasm.	Total No. of Term. Chiasm.	Mean Chiasm. Frequency.	Term. Coeff.
Female	100	197	86	1·9	0·43
Male .	100	147	100	1·4	0·67

quency per bivalent is 1·9 and terminalisation coefficient 0·43, whereas in the male it is 1·4 and 0·67. Since the animals examined had the same genetic constitution, the differences in chiasma frequency could not be due to genic dissimilarity.

These observations strongly support the partial chiasmatype hypothesis of crossing-over.

Measurement of the Electricity liberated during Downgrade Reactions of Organic Compounds

MR. WOLFENDEN'S letter on this subject [1] has, I regret, only recently come to my notice. I had thought that our correspondence had cleared up the points at issue. I would point out that the liberation of electricity by the action of micro-organisms during the downgrade reactions of organic compounds, as set forth in my paper,[2] has been confirmed by Elema,[3] Gillespie,[4] Hewitt,[5] and others, and my results are quoted as the starting-point for the investigations of oxidation-reduction potentials in biochemistry and bacteriology. In this paper it was emphasised that the electrical effects only occurred under conditions favourable to the growth of the micro-organisms in question.

It is well known that aqueous solutions of pure sucrose are unsuitable for the growth of yeast, and that little or no fermentation takes place when these culture media are employed. When, however, sucrose is used in Pasteur's solution, fermentation proceeds rapidly.

In my experiments I have found that sucrose and the highly refined cane sugars are unfermentable with

yeast and give no electrical response.[6, 7] On the contrary, the unrefined sugars, such as Barbadoes, give a vigorous fermentation and corresponding electrical response. It is not therefore surprising that Mr. Wolfenden's experiments conducted with pure sucrose gave negative results, and the discrepancy between us may thus be explained.

In the two sets of experimental conditions Mr. Wolfenden used pure sucrose while I used unrefined sugar, and I cannot agree that "it seems unlikely that the impurities could play a decisive part", as they evidently promote yeast-sugar fermentation and thus constitute a decisive factor in the electrical response.

Hydrolysis in Green Plants by Moonlight

IN view of the recent interesting discussion on 'Lunar Periodicity in Organisms', which has appeared in these columns,[1] some very simple experiments, carried out in South Africa in the grounds of Huguenot University College, would appear to throw some light on the subject.

On a bright moonlight evening, about 10.30 P.M., on the 9th day of the moon, that is, near the time of maximum polarisation, I noticed a very sharp shadow cast by a vine leaf on the one beneath it, the tip being very brightly illuminated. The lower leaf was picked

FIG. 1.—Hydrolysis of starch by exposure to moonlight of lobes *F*, *E* of a vine-leaf.

and quickly plunged into 95 per cent alcohol. On staining with iodine, a remarkable disappearance of starch was found to have occurred in the portion irradiated by the moonlight (Fig. 1, *E* and *F*), while the basal portion *ABCD* in shadow still retained its starch.

Similar results had previously been found on exposing leaves of spinach and *Tropæolum* to moonlight, a portion of the leaf having been covered by cardboard or tinfoil. The exposed part of the leaf showed distinct hydrolysis, while the starch remained in the covered part.

Filtration of ...

FOLLOWING upon the publ... letter from Mr. MacClement an... upon the above subject,[1] it ma... cording the results of some si... direction. During the past nine m... filtering two potato mosaic viruses,... means of the same collodion membr... developed by W. J. Elford. This wo... carried out at the Molteno Institute at ... under the direction of Prof. D. Keilin, to wh... deeply indebted. I wish also to express my th... Dr. W. J. Elford for much assistance willingly give...

Before attempting to filter these two potato viruses through the collodion membranes, some preliminary filtration work was carried out with Pasteur-Chamberland candles. These experiments showed that while the *X* virus was filterable through an L_3 and occasionally an L_5 candle, the virus *Y* would not pass an L_1 candle. The experiments on filtration through the collodion membranes, while admittedly preliminary, showed that *both* viruses would pass a membrane of approximate pore size 0·35μ, and that both are held back by membranes of 0·15μ. This is a parallel case to that quoted by Messrs. MacClement and Henderson Smith, where Dr. Hamilton's virus would not pass an L_3 candle but would pass a membrane of 0·30μ pore size.

The inability of the *Y* virus to pass the L_1 candle is obviously not directly connected with the porosity of the candle or the size of the virus particle, but in all probability it is due to adsorption of the virus by the candle. I have found that if the virus complex, $X + Y$, is merely passed through a kieselguhr bed in a Buchner funnel, the filtrate invariably contains a 'pure culture' of the *X* virus, the *Y* being completely adsorbed to the kieselguhr; this offers a ready means of separating out a complex of these two viruses.

Production of Microscopic Test-Rulings

IN NATURE of Sept. 19, 1931, under "Birthdays and Research Centres", I claimed that microscopic test-rulings up to 250,000 lines per inch had been produced in my laboratory.

Lately, for various reasons, I found it necessary to make a personal investigation into this claim, and I regret that I have been unable to find any evidence that rulings beyond 120,000 lines per inch have been produced here.

The results for various areas are summarised, and certain reservations made in regard to the quaternary period, though a post-glacial optimum during the neolithic is confirmed.

Indian String-Games.—Dr. James Hornell has published a number of string-figures from Gujarat and Kathiawar (*Mem. Asiatic Soc. Bengal*, vol. 11, No. 4). In his introductory remarks, he points out that this is the first successful attempt to collect 'cat's cradles' from Indian sources, and that only two had previously been published. It is surprising to find that none of the collection is of any complete animal or flowering plant, though this may be due to the fact that the great majority of informants were town-dwellers. The figures are mostly taken from the common objects of life: scissors, a saw, a mirror, a lock and key, a betel plate, handcuffs, etc. Three figures represent fruits, two a bird's feet, and one the nest of a crane. Mythological subjects are not represented. With the exception of the cosmopolitan Eurasian cat's cradle, nine of the ten games found outside India are common to India and Africa. The tenth game, the 'crane's nest', is also found in Africa, but is worked out by different moves. This common distribution emphasises the long connexion of Indians with Africa, and in particular, that of the traders and sailors of Gujarat and Kathiawar with East Africa, through a trade which goes back fully two thousand years. This is undoubtedly the main factor in this remarkable community of string-games. It is urgently necessary that ethnologists should collect the games in inland regions and among hill-tribes, to determine how far the games now described are indigenous to India and how far borrowed from African sources.

Rainfall and the Distribution of Birds.—A study of the birds of south-western Africa, made during an expedition lasting for two and a half months in 1930, leads Baron Rodolphe Meyer de Schauensee to the conclusion that the distribution of the birds in the region is governed largely by rainfall; altitude seems scarcely to play any part as a barrier (*Proc. Acad. Nat. Sci. Philadelphia*, vol. 84, May 1932, pp. 145-202). The region investigated comprises three areas delimited by rainfall averages of 0-10 in., 10-20 in., and 20-40 in. A striking example of the relation between this factor and the presence of a geographical race occurs in the case of *Saxicola torquata*. The race *salax* was first described from the Gaboon, but de Schauensee found it near the Victoria Falls—apparently a case of discontinuous distribution, for the intermediate region of Central Angola contains the race *stonei*. The explanation is that *salax* follows the rainfall region of 20-40 in. around the area occupied by *stonei*, so that the former appears quite naturally to the north and to the south of the latter race. Other striking examples are given, and although the expedition was too short to make the observations adequate (558 birds were collected, representing 254 species and subspecies), the seeming significance of the association and the fact that it explains some otherwise inexplicable problems of distribution suggest that it well deserves further testing.

The Arachnid Order Chelonethida.—Under the foregoing title, Dr. J. C. Chamberlain has contributed an extensive memoir of 284 pp. which forms No. I. of volume 7 of the Biological Series published by the Stanford University, California (1931). The Chelonethida or pseudoscorpions, as they are more familiarly termed, are dealt with from two points of view, namely, morphological and taxonomic. The morphological section of Dr. Chamberlain's work provides the most complete account available of the exoskeletal parts, and is accompanied by a wealth of clear text-figures. There is a full discussion of range of form and structure within the order, and full use is made of the morphological data thus brought together in dealing with the taxonomy of the group. As the result of these studies, the author has completely revised and reorganised the systematics of the group. Older and inadequate systems of classification have been largely discarded and a new taxonomy given in their place. The author has found it necessary to name about fifty new genera and one hundred and fifty, or more, new species. These, however, are all described in papers now in course of publication elsewhere, with the result that the present memoir is largely freed from the mass of purely descriptive matter, and is directed more especially to general classification. The work is one which students of the Arachnida will welcome, and its utility is enhanced by a bibliography listing some 311 titles and by full indexes to both text and illustrations.

Vitamins and Fungi.—Most of the work on vitamins has been performed on higher animals with the view of growth stimulation, but Y. Tochinai and M. Terui, two members of Hokkaido Imperial University, Japan, have studied the effects of vitamin A on various fungi ("Studies on the Effects of Fat Soluble Vitamin upon the Growth of some Parasitic Fungi", *J. Fac. Agri.*, Hokkaido Imp. Univ., Sapporo, Japan, vol. 32, pt. 3, pp. 71-107; 1932). The fungi *Helminthosporium turcicum* and *H. Oryzæ* were both retarded in growth by high concentrations of vitamin A, though the latter fungus was stimulated slightly by low concentrations of the vitamin. *Gibberella Fujikuroi* reacted like *H. Oryzæ*, whilst *Colletotrichum lindemuthianum* was similar to *H. turcicum*, being inhibited by high or low concentrations of vitamin A. Olive oil was the solvent for the growth-promoting substance, so parallel cultures with the oil alone were inoculated with the fungi in order to be sure that the observed effects were due to the vitamin. Whilst *H. turcicum* and *G. Fujikuroi* were indifferent to olive oil, the other two fungi were stimulated by it, though not sufficiently to mask the effects of the vitamin A.

The Permian Yellow Sands.—Dr. M. B. Hodge has made a detailed investigation of the Yellow Sands of north-east England (*Proc. Univ. Durham Phil. Soc.*, **8** (5), 410-458; 1932). Elutriation shows that there are two dominant grades, one between 0·05 mm. and 0·15 mm., the other between 0·6 mm. and 0·8 mm. This is taken to indicate æolian transportation of the grains. The heavy minerals agree in species and type with those of the Scottish Carboniferous rocks. The quartz grains are frosted and the larger ones well rounded. The inclusions indicate a dual granitic and metamorphic source. It is concluded that the Yellow Sands were mainly a deposit of sand on the shore of the Permian sea, the material being derived partly from Carboniferous sandstones near by and partly from a crystalline area to the north. While the Sands were being laid down on the shores and along the adjoining coastal strip, the Marl Slate was accumulating as a calcareous mud in lagoons fringing the shores. With the sinking of the coast the lagoons were gradually invaded by the sea, from which the Lower Magnesian Limestone was deposited. While these changes were in progress the æolian sands would occasionally be blown into the lagoons, giving rise to the intercalations of sand with shale and limestone now found. The three deposits seem to be in part contemporaneous, although the general succession is, as usually stated, from Yellow Sands through Marl Slate to Lower Limestone.

Petroleum Genesis and Volcanic Ash.—For some time past it has been common knowledge that the production of artificial petroleum from animal or vegetable oils by distilling them with different adsorbent materials, for example, clay, charcoal, calcium carbonate, diatomaceous earth, has been achieved. A more sharply focused problem in this connexion has recently engaged the attention of Japanese investigators, who took advantage of the volcanic eruption of Komagadake, Hokkaido, in 1929, and secured from the Earthquake Research Institute some of the ash ejected. Using this material as the adsorbent, extensive physical and chemical tests were carried out with different oils, partly to ascertain the action of the ash thereon, also to see whether the results threw any light on the origin of petroleum in the Japanese oilfield (T. Terada, M. Hirata, and T. Utigasaki, *Scientific Papers*, Institute of Physical and Chemical Research, Komagome, Hongo, Tokyo, No. 343, 1932). The results show that the action of this ash on the oils tried is to produce a distillate closely resembling ordinary kerosene so far as physical properties are concerned, though differing from the petroleum product in chemical behaviour, notably in its reaction to strong sulphuric acid, which points to the presence of a predominance of unsaturated compounds. Notwithstanding this, the authors claim that there is decided possibility that much of the Japanese oil has originated from animal or vegetable oily matter buried beneath volcanic ash.

International Standards.—The degree of accuracy which has now been secured in the international measurement of capacitances is well brought out in a communication by Mr. H. L. Curtis and Miss C. M. Sparks, of the U.S. Bureau of Standards, and Messrs. Hartshorn and N. F. Astbury, of the National Physical Laboratory, to the April issue of the *Journal of Research* of the Bureau. The capacitance of a subdivided mica-tinfoil condenser of 1 microfarad was measured alternately at Washington and at Teddington, at the former by comparison with a standard air condenser the capacitance of which was measured in terms of resistance and time by Maxwell's method, at the latter by comparison with the standards of resistance and mut. capaci Washin 1·0019, 1 while at Te The unit of therefore iden thousand.

Measurements ... **Sweden.**—A recent *Circular* (March 25) co at Abisko on the intens A. Corlin. Both a Kolhö a standard Steinke chamb at a number of other places the data from different parts used. The results obtained are tail, the paper being chiefly devo the methods of observation and of but several points of much interest. Perhaps the most significant is that, a daily variations, the intensity of the radi closely constant at this high latitude (68 correcting for changes in the barometer, as found farther south. In the Abisko obse made to the north of the arctic circle, the every expectation that meteorological effects an an influence of the aurora, if these existed, would be detected. The rate of ionisation under standard conditions is given as nearly 2·78 *J*. Another point, which might have been anticipated, but which it is, nevertheless, satisfactory to have demonstrated directly, is that humidity, as well as temperature, has no perceptible direct influence upon the penetrating radiation, and that the correlation between ionisation on one hand and humidity and temperature on the other is wholly due to the existence of a correlation between ionisation and air pressure. Publication of the full record of this work will be awaited with much interest.

Infra-Red Photomicrography.—The recent placing of infra-red sensitive plates upon the market has stimulated many inquiries as to possible new applications of photographic methods. In a communication to the Eighth International Congress of Scientific and Applied Photography held at Dresden in August 1931, Prof. Köhler and Dr. Paul Kraft of Jena described results obtained with infra-red plates in photomicrography. Three typical examples of objects opaque to visible light but transparent to infra-red rays of about 8000 A. are shown in their paper; these are woollen threads dyed black, the head of a flea, and a fossil from coal. In each example a very great improvement in the detail of structure revealed is evident where infra-red sensitive plates were used. The magnification employed ranged from 20 to 76 diameters.

Corrosion Resistivity of Metals.—Many methods have been devised for following the velocity of metallic corrosion; the loss of weight, the loss of strength, the loss of conductivity in the metal, the evolution of hydrogen, the absorption of oxygen, and even the evolution of heat, have all served as measures of corrosion under different conditions. Lately, Mr. E. W. Zehnowitzer, of the Institute of Metals, Leningrad, has used conductivity changes in the *liquid* for the same purpose, introducing into his corrosion vessel two platinum electrodes, connected to a Wheatstone bridge in the familiar manner. His results, communicated in a letter to the Editor of NATURE, show that during the corrosion of zinc by sulphuric acid the conductivity of the liquid steadily falls, whilst during attack by distilled water it rises; the

r f, involving the distance of closest approach, a, of the ions, has been deduced by Debye and Hückel. Neumann (*J. Amer. Chem. Soc.*, June), by experiments on the solubilities of silver chloride in solutions of various sulphates and nitrates, finds marked deviations from the Debye-Hückel limiting law as well as from a first approximation formula, even at the lowest concentrations, in the case of sulphates and lanthanum nitrate. The sulphates of unsymmetric valency type exhibit deviations of fluctuating sign from the limiting law when the observed activity coefficient is plotted against the square root of the ionic strength. The symmetric sulphates show only one positive deviation, potassium and barium nitrates scarcely any. The extension of the Debye-Hückel equation due to Gronwall and La Mer (NATURE, **128**, 499; 1931) gives values of a in good agreement with experiment in the case of the symmetrical sulphates and nitrates, but does not explain the peculiar behaviour of the unsymmetrical valency type sulphates, except possibly as a first approximation.

Astronomical Topics

tion of Borrelly's Comet.—This comet was covered in 1905 and has been observed at every return since. Its period is so close to seven years that the conditions have been favourable for observation at all the returns. Two predictions of the conditions of this return were made: W. P. Henderson and J. D. McNeile (B.A.A. Handbook) gave Aug. 26·268 for the perihelion passage; M. Schaumasse (*U.A.I. Circ.* 365) gave Aug. 27·816. The truth appears to lie between them. The comet was detected by Prof. G. van Biesbroeck at Yerkes, July $30^d\ 9^h\ 6{\cdot}2^m$ U.T., the position being R.A. $5^h\ 31^m\ 54{\cdot}67^s$, N. Decl. 13° 2′ 13″ (equinox of 1932·0). The date of perihelion given by the R.A. is Aug. 26·690; the declination gives Aug. 27·171. The comet was of magnitude 12 at discovery; as it is approaching the earth until the end of the year it is likely to become brighter. The comet is a morning object in Gemini; the ephemeris in the B.A.A. Handbook will suffice for finding it. An ephemeris is also given there for Brooks's comet, which is likely to be found shortly; two independent computers, Mr. F. R. Cripps and Prof. Dubiago, both find Oct. 7·6 for the perihelion passage; the conditions this year are very favourable for observation, as the comet is in opposition when in perihelion.

Meteor Observations in New Zealand.—An article on meteors by R. A. McIntosh, of Auckland, New Zealand (*J. Roy. Ast. Soc. Canada*, May–June), is welcome since it shows that systematic observation of meteors is now carried on in those islands. For a long time the statistics were based solely on observations made in the northern hemisphere; obviously the inclusion of southern observations adds greatly to their value. When we walk beside a tram-line, more cars meet us than overtake us, since our motion shortens the interval in one case and lengthens it in the other. In the same way, more meteors meet the earth than overtake it. Now, these meteors that are meeting us come from the earth's apex, or point towards which it is moving in its annual revolution; this is a point in the ecliptic 90° behind the sun, which rises some six hours before the sun, or about midnight. Hence the 'meeting' meteors are chiefly visible after midnight, which explains the fact that more meteors are seen in the small hours than before midnight. The apex is at its farthest north in September, so we should expect a maximum of meteors in northern countries in that month; actually the diagram of Mr. McIntosh shows it in August, with a well-marked minimum in the spring; it is doubtless affected by the rich Perseid shower in that month. The diagram that he gives for the southern hemisphere does not show the seasonal effect so clearly; there is certainly no maximum about March, as we should expect; on the contrary, there is a succession of rich months from May to October, the cause for which is not clear. But the diagram of the numbers of meteors for different hours of the night agrees well with theory, and shows a maximum at 3 A.M. The slight falling off after that may be due to dawn, or to fewer watchers. Mr. McIntosh alludes to the effect of Jupiter's action in diverting the Leonid meteors so as to miss the earth in 1899; but he omits to note that the calculations of the B.A.A. Computing Section give hopes that this action may be reversed in 1932.

The Ritchey-Chrétien Reflecting Telescope.—The *Scientific American* for July contains an article by A. G. Ingalls on the improvements which M. Chrétien and Prof. Ritchey are carrying out in the design of the Cassegrain reflector. It is well known that star images in photographs taken with reflectors are generally good in the middle of the field but deteriorate greatly towards the edges of the plate, where large wings generally appear, making accurate determination of position or magnitude difficult. This is because the paraboloid form of the mirror gives good results for rays parallel to the axis, but not for oblique rays. The first improvement is to make the large mirror a hyperboloid instead of a paraboloid. The form of the secondary mirror is much more complicated; it is on the hyperboloid side of the paraboloid, but cannot be described by any simple name, since different zones are specially designed to give the best results. It is also proposed to use slightly concave plates, the curves being designed in conjunction with those of the mirrors. It is noted that the new reflectors are shorter and therefore lighter than the old, so that some of the extra cost of the mirrors is made up by the smaller dome. The article also mentions that Prof. Ritchey has designed new methods of guiding the telescope during exposures, which make the following simpler and more rapid. Two keys, one accelerating, the other retarding, are held in the hands, while an occulter, to cover the plate during moments of bad definition, is worked by the lips. The instrument now under construction has aperture 40 inches, but it is hoped to extend the method to much larger sizes; if so, the cellular type of mirror will probably be used.

Archæological Studies in

AN outstanding feature of the first International Congress of Prehistoric and Protohistoric Sciences held in London last week was afforded by the group of lectures which were delivered at the general meetings of the Congress held on the evenings of Aug. 2, 3, and 5, and on the morning of Aug. 6, to which the presidential address on the afternoon of Aug. 1, and the exhibition of British archæology in the field at the London Museum, to which reference was made in NATURE of Aug. 6, p. 196, had formed an appropriate introduction. While Sir Charles Peers, in his address on "The Beginnings of British Archeology", had traced the stages by which interest in the exploration of the past had attained the status of a scientific study, and the exhibition had given a practical demonstration of what is now being achieved in the field, Dr. Cyril Fox, Mr. E. T. Leeds, and Mr. T. D. Kendrick laid before their audiences the results of synthetic study of the facts most lately won in the field at three strategic points in the early history of the British Isles. The picture was completed on the morning of Aug. 6 by Mr. O. G. S. Crawford's account of Britain's achievement in the development of archæological discovery by photography from the air, which was so admirably illustrated by the photographs exhibited by the Ordnance Survey at the London Museum.

Sir Charles Peers, in his presidential address, while tracing the spirit of the archæologist back to the interest of primitive man in his predecessors, distinguished the latter as a hope for treasure, while around the great monuments of the past, which have never failed to arouse the attention of the living, has collected a mass of material, sometimes dignified by the name of folk-lore, which should not be overlooked. Early antiquaries explained prehistory in the light of history as known to them. When anything remarkable remained, the natural tendency was to ascribe it to the Romans. Camden, the learned forerunner of modern antiquaries, saw no reason to ascribe a date before the Roman occupation of Britain to any notable monument except Stonehenge—*insana substructio*. Aubrey, the Wiltshire squire, said Sir Charles, had the definite merit of setting down what he saw. In 1648 he was impressed by the absurdity of deriving such structures as Avebury from the classical tradition. He was persuaded that Stonehenge was a temple of the Druids. Then came William Stukely, a man gifted with a vivid imagination and an insatiable curiosity. "What is all learning", he said, "but a knowledge of antiquities?" Sir Charles then reviewed the work of Sir Richard Colt Hoare, whose book on the Wiltshire monuments, of which the first volume was published in 1810, was prefaced with the words, "we speak from facts not theory"; of William Smith, whose geological map of England demonstrated a succession of ruined worlds, opening the way to a new conception of the prehistory of man; and of John Frere, who attributed his palæolithic implements to a period "even beyond the present world"—the transition from ancient to modern archæology.

Dr. Cyril Fox, in his address on "The Personality of Britain", dealt with some of the fundamental principles of prehistory, demonstrating the bearing of climate and soil, and the resulting vegetable and animal life, on man and his history. As a whole, these represent man's environment and Britain's personality. The position of Britain, he said, adjacent to five hundred miles of European coast, renders the country liable to invasion, while its indented outline is convenient for invaders, and its estuaries and slow-moving rivers invite penetration. Of the three main routes fo. Channel, o. that by the narrow gorge, higher; but wh. Britain to its no. concentrate on Ke.

Dr. Fox then proc. division of the island . Clyde isthmus into a w. eastern lowland zone led . on the east, which was ea. while in the highland zone . the same way the fertile lowla. populations, while north of the the Highlands tended to devel. Influences from Ireland were usua. highland zone. The lands washed b. thus tended to develop cultural unity. way, soil was the controlling factor in . tribution and elevation in the highland, as . not stand the cold. The most complete man. of any primitive culture entering eastern or so. Britain from the Continent focused in the Salisbu. Plain region, but as civilisation developed, overseas trade moved in the direction of the Thames estuary and a change came in the type of soil and country desired by the inhabitants. Hence the progress from subjection to environment to control of environment, from barbarism to civilisation, is expressed by the utilisation of oak forests and the substitution of arable fields.

In "Celtic Art in Britain", Mr. E. T. Leeds sought to trace the origins and development of an artistic epoch which lasted from its beginnings in La Tène style down to the eleventh century of our era. It was first implanted on the south coast, probably in the late fifth or fourth century B.C., and taking root firmly in the third century B.C., when it began to discar. the naturalistic tendencies of the parent continenta. school in favour of geometrical arrangements of curving lines. This school found its most brilliant expression in a western school, the districts first occupied by iron age peoples, which permeated the eastern Midlands and spread to Yorkshire and beyond. A period of decadence ensued. While intruding Belgic tribes developed *champlevé* enamelling, the British craftsman attempted novel designs by "breaking the back of the curve".

Before the Roman conquest, southern Britain was falling under the influence of continental mass production. There is a loss of originality and an increase of formalism. Small geometrical designs in enamel aim at a jewelled effect: on the periphery of the Roman occupation, however, Celtic art survived and the Celtic genius adapted classical models as in the Æsica brooch. A fresh burst of activity set in as seen in the enamelled escutcheons of the Winchester and other bowls, a group confined to the east of the Fosse Way. The outcome was the trumpet scrolls beloved of the Celt with his feeling for the curving line. This renaissance in southern England in the sixth and seventh centuries, in conjunction with certain zoomorphic designs, provides the key to the sudden appearance in Ireland at the close of the seventh century of such masterpieces as the Book of Durrow, unheralded by anything in the previous art history of the island.

Mr. T. D. Kendrick, in "The Crafts in Ancient Britain", dealt with the difficult but none the less interesting period of the Early Dark Ages, holding

ɩhe
ɹrian
ɹrelius
, to the
objects are
. the Briton
round in the

graves of his conquerors. Investigation of the chronological position of such material as the famous 'Kingston' brooch shows that it is more likely to be British than Jutish, as it has been regarded. There is a definite probability of some progress in the task of sorting out minor Arthurian antiquities from the 'Anglo-Saxon' cases of the museums.

The quantity milled annually exceeds that ...all other species combined, and during the year ...ding March 31, 1930, totalled 159,000,000 ft. Board Measure (B.M.), or 58 per cent of the total timber production of the Dominion. In 1920–1930 the annual cut of the species exceeded 140,000,000 ft. B.M., the peak production of 195,000,000 ft. B.M. in 1926 representing 55 per cent of the total timber produced that year. That the fellings are exceeding the annual increment or possibility is exemplified by the statement that a few years ago Auckland supplied a far larger proportion of the total cut than any of the other districts, but its accessible supplies have now dwindled, and Westland has taken the lead and is said to be likely to supply an increasing percentage in future years.

The first detailed statistics on the export of rimu ...ere collected in 1913, when 8,500,000 ft. B.M. were exported. In the War years the trade increased, and by 1918 the total exports had reached 30,000,000 ft. B.M. This was due to the difficulty in obtaining supplies of North American and Scandinavian timber during the War years. With the drop in price of the foreign species at the end of the War, and low ocean freights, it was possible to land the foreign material cheaper in Australia than rimu. The exports of the latter to Australia had fallen to 4,000,000 ft. B.M. in 1925, and have remained at that figure ever since. Recent customs duties on foreign timber in Australia now permit rimu to compete successfully once more, and a recent survey has shown that 20,000,000 ft. B.M. of rimu could be used in Australia annually.

The leaflet is written from the marketing and manufacturing point of view. It is to be hoped that the Forest Department will bear in mind the great value to the country of this fine timber, and will take steps to see that its regeneration is undertaken, in order to perpetuate supplies.

The rimu is a fine forest tree, the height in the average commercial stand varying from 60 ft. to 120 ft. When mature, its trunk is long, straight, unbranched, and with little taper, carrying a comparatively open and irregular crown. From the remarkable weeping habit of its foliage it is the most easily recognised and best known of all New Zealand trees. The commercial bole usually varies from 40 ft. to 80 ft. in length. Its diameter, breast height, in mature stands varies from 2 ft. to 4 ft., although it is said that many of the trees at present converted range below the lower limit. In other words, as is invariably the case when primeval forests are lumbered, immature trees are being felled along with the mature ones. Occasionally trees up to 8 ft. diameter are encountered and milled. It might be suggested that a few stands of these fine old trees should be selected by Government and reserved to show future generations what the New Zealand soil is capable of producing.

Although the tree grows on flat, but not marshy, land, it favours undulating localities and hillsides, being found at all altitudes from sea-level up to 2500 ft. With the exception of the pure beech (*Nothofagus*) stands, rimu occurs in every major type of forest growth, and in the North Island it is an occasional associate of the kauri.

Mr. Ward gives interesting details on manufacture, seasoning, grading, the properties of the wood and durability, and adds notes on its utilisation by various industries.

Winter Climate of Greenland

IN a paper read to the Royal Geographical Society on April 18, by Mr. S. T. A. Mirrlees, new light is thrown on the winter climate of the interior of southern Greenland. Mr. Mirrlees pointed out that nearly all our knowledge of the climate of this region is based upon observations made on summer sledge journeys, supplemented by the observations made throughout the year at the various coast stations of the Danish Meteorological Service. Greenland lies to the north of the region of the world's most persistent cyclonic activity, but—if we accept as accurate the distribution of high and low pressure shown on the daily charts of the British Meteorological Office and similar older publications, such as those of the Danish Admiralty—is at all seasons liable to be invaded by the cyclonic depressions of the North Atlantic.

In a series of observations made every three hours between Sept. 8, 1930, and April 26, 1931, at about lat. 67° N., long. 41° W., at a height of about 8250 ft., by the British Arctic Air Route Expedition, his hypothesis is confirmed. The direct influence of the Atlantic depressions on the weather was found normally to be small, as is shown by the low figures for the monthly mean proportion of the sky covered by cloud, which varied from five-tenths in September to three-tenths in February. The mean for the whole period must therefore have been roughly comparable with the normal for the French Riviera. But there were some stormy periods and even gales, and the strongest winds showed no tendency to be more prevalent from the prevailing northerly direction of the wind than from other quarters; moreover, the characteristic changes of wind, pressure, and weather caused by the passage of the centre of a depression directly over or to the north of the place of observation were observed.

Very low temperatures had been expected, and were not wanting, for a reading of −59° F. was

catalytic action of the lime on the course of hydration.—**Urion**: Cyclopentenyl-alkylcarbinols and their dehydration products.—**Henri Erhart**: The soils of the Rhine terraces to the south of Alsace.—**Lefèvre**: The presence of peridinians in a fossil deposit at Barbadoes.—**Feng Yen-An**: The presence of centrosomes and of star-shaped forms in an angiosperm, *Lonicera alpigena*.—**Pierre Dangeard**: The vacuome of Algæ and its transmission by the zoospores.—**A. Guilliermond**: The structure of bacteria.—**Marcel Mirande**: The evolution of hydrocyanic acid by certain fungi.—**H. Heldt**: Aerial observations for the localisation of shoals of tunny fish and the possibility of the direct study of their migrations. From an aeroplane it is possible to discover the shoals of tunny and fix their size, position, and direction of movement.—**Mme. C. Vincent** and **J. Vial**: Researches on the yields of milk and of fat in human lactation.—**L. Bugnard** and **C. Soula**: Glycæmic equilibrium and digestive secretions.—**A. Gruvel**: Some observations concerning the large lake Amer (Suez Canal). A discussion of the effects of variations of salinity on animal life in the lake.—**Marcel Avel**: The regenerating power of the dorsal and ventral halves of the body wall, in the cephalic region, in *Lumbricus*.—**A. Dognon**: The biological action of monochromatic X-rays of different wave-lengths on the egg of *Ascaris megalocephala*. The action of the X-rays, in the case of the cell studied, diminishes suddenly at the wave-length 1·54 A., and then remains constant down to the shortest wave-length studied (0·7 A.).—**A.** and **R. Sartory**, **J. Meyer**, and **M. Antonioli**: The presence of a pigment resembling prodigiosine in *Actinomyces Allenbachii*. The colouring matter was isolated in crystals as chlorhydrate and perchlorate. Its chemical and physical properties, especially the spectroscopic analysis, closely resemble those of prodigiosine.—**A. Dorier**: The larvæ of *Parachordodes alpestris*.—**Ch. Joyeux** and **J. Piéri**: The rabbit as a reservoir of virus for exanthematic fever.

GENEVA

Society of Physics and Natural History, April 28.—**R. Wavre**: Extension of a theorem of Stokes relating to fluid stars. Generalising the classical theorem of Stokes and of Poincaré relating to planetary figures, the author shows that the attraction of a fluid star (or nebula) on other stars depends only on its total mass, its free surface, and superficial accelerations. The distribution of matter in the interior of the star is without influence.—**M. A. Schidlof**: (1) The evaluation of the difference between the masses of the α_1- and α-particles. The difference between the masses of these particles of a nucleus is evaluated by a method not making use of the Gamow-Condon-Gurney threshold maximum potential. For two different nuclei (Th^{232}, Pb^{208}) concordant values are obtained, which confirm the value previously deduced from the threshold theory.—(2) The arrest of the periodic systems of the atoms and the greatest electronic concentration of the nuclei. Utilising the value of the mass effect by the proton, calculated by considering the presence of the particles in atomic nuclei of the thorium series, the author has deduced from the condition of the possibility of equilibrium the upper limit of existing atomic numbers. The inequality utilised in this calculation also furnishes the upper limit of the electronic concentration of compound nuclei.—**E. Briner**, **J. Bron-Stalet**, and **H. Paillard**: Researches on the dehydration of phenol. Contribution to contact catalysis. The authors have studied the dehydration of phenol in the presence and absence of a catalyst. In the presence of thoria, the reaction takes place rapidly up to a transformation of 60-64 per cent of phenol into phenyl oxide. If the catalyst is absent, the dehydration of the phenol is very slow but complete.—**A. Naville**: The cytological bases of the theory of crossing over in the Diptera. The author shows that in *Calliphora erythrocephala* at the commencement of ovocytary evolution a series of premeiotic phases is observed, allowing a parasyndesis, and capable of explaining crossing over. In spermatogenesis, nothing similar is observed and the spermatocytes enter directly into diakinesis without undergoing premeiosis. If these results can be extended to other Diptera, they constitute a striking verification of the hypothesis of Morgan and Sturtevant on crossing over in *Drosophila*.—**E. Cherbuliez**, **E. Ehninger**, **K. Bernhard**: The multiplicity of principles in the croton seed. The authors have extracted from croton oil a substance which is a powerful vesicant but has no purgative effect, while the oil left after its removal retains its purgative properties. Hence there are at least two active substances in croton oil.

VIENNA

Academy of Sciences, April 28.—**Wolf Johannes Müller** and **W. Machu**: Theory of passivity phenomena. (15) The passivating action of oxide layers in the anodic passivation of iron in neutral sodium sulphate solution.—**Anton Kailan** and **Walter Haas**: Velocities of esterification of methyl and ethyl alcohols in acetic acid. The esterification constants are given for acetic acids containing different amounts of water and in presence and absence of hydrochloric acid.—**Franz Fuhrmann**: Studies on the biochemistry of luminous bacteria. (2) Influence of sugar, with sodium chloride, on the luminosity. Addition of glucose, fructose, or galactose to cultures of *Photobacillus radians* containing 0·5 or 0·25 M. sodium chloride usually effects no, or but slight, rise in the luminosity. During the early stages of growth, sucrose and lactose enhance the luminosity, and maltose in small proportions causes an increase, but in larger quantities a decrease.—**Friedrich Hopfner**: The fundamental equations of physical geodesy. Determination of the mean level of the earth's surface from gravitation values depends on combination of Bruns' theorem with the solution of a partial differential equation of the first order. Former known solutions of this problem differ only in form, being variants of the solution of the differential equation.—**Otto Fürth** and **Eduard Herbert Majer**: (1) Accumulation of carbohydrate in the liver of lard-fed rats. The formation of glycogen in the liver has been studied with rats fed on lard together with either crude fibre or the sodium salt of one of the organic acids formed during the digestion of fibre in the intestines. Glycogen is formed from beet-slices or fermentation lactic acid, but not from butyric, succinic, or valeric acid. These lower acids are either resorbed from the intestine and possibly used in building up fat, or assimilated by micro-organisms and used in the construction of body-substance.—(2) Phlorizin glycosuria of the pig.—**Gustav Götzinger** and **Helmut Becker**: New discoveries of fossils in the Wienerwald.—**Herbert Haberlandt**: Luminescence of fluorites. Some fluorites exhibit red fluorescence, but none of these shows rare-earth lines in the spectroscope. Many fluoresce after irradiation with β-γ-rays and some only after ignition and irradiation, whilst others display no fluorescence.—**Fritz Rieder** and **Elisabeth Rona**: Range of α-rays of actinium products. Investigation of the α-rays of RdAc reveals two prominent grou[illegible] with the ranges 4·7 cm. and 4·35 cm. respect[illegible] together with three other groups. Prep[illegible] AcX free from RdAc show groups [illegible] 4·1 cm., 4·3 cm., and 4·6 cm., an[illegible] (5·00 cm. and 5·40 cm.). Ac[illegible]

a fine structure, as it gives, besides the known group of 6·47 cm. range, two faint groups of 6·35 cm. and 6·60 cm. range.—**Rudolf Leutner**: Velocity of hydrolysis of cyclic acetals (1).—**Konrad Funke**: Perylene and its derivatives. (35) Diaminoperylene-3: 10-quinone.

May 6.—**Karl Brunner** and **H. Moser**: 5-Ethoxy-indolinone.—**Arthur Haas**: Relation between the world's radius of curvature and the radius of the electron.—**Franz Rücker**: Reflection and transparency of animal tissues in the ultra-red. Considerable proportions of infra-red rays traverse the skins of reptiles and amphibia. Thus, with many lizards, 3-4 per cent of the radiation passes through the whole covering of the body, including the black peritoneum, into the body. The influence of the chromatophores is seen particularly well with the tree-frog; almost twice as much of the radiation is transmitted by the skin of the back when the chromatophores are partially contracted as when they are expanded. The chitin of insects is also transparent to some extent. The skins of xerophile, thick-skinned snakes, are usually far less penetrable by the rays than those of the shade- and moisture-loving forms.—**Julius Pia**: The Girvanellæ of the English carboniferous limestone. Three species of *Girvanella* from this source have been named, but the author considers that only two have been clearly distinguished; namely, *G. ducii* Wethered and *G. staminea* Garwood (? *G. incrustans*).—**Johann Koppmair**: General solution of the fundamental problem of photogrammetry.—**Alois Zinke**: Perylene and its derivatives (36).—**N. A. Puschin** and **M. Deželić**: Equilibrium in systems with erythritol as a component.—**N. A. Puschin** and **J. J. Rikovsky**: Compounds of carbamide and urethane with acids and phenols.

Differential Fertility and Family Allowances *

THE Registrar-General is a maker of castes: he divides his people into classes according to the social status of the occupations which they follow, but his classes are to be distinguished also by differences in wealth, in culture, and in reproductivity. It is this differential reproductive rate that alarms the eugenist.

The number of children per married couple represents the contribution of a social or occupational class to the next generation, and this contribution differs very markedly from class to class as one passes in review from the teachers on towards the occupational class of the general labourer. It matters not whether one uses the yard-stick of social status, of wealth, or of culture, one finds that, on the average, the most socially eminent, the wealthiest, and the most cultured classes exhibit a much lower reproductive rate than do the socially submerged, the poor, and the uneducated.

The relative reproductivity of the different classes will be determined by differences amongst them in the birth-rate, which is a true reflection of the operation of all those agencies which raise or reduce fecundity, which condition the frequency of mating, which render fertilisation more or less certain, and which influence the viability of the embryo and fœtus. In this connexion, therefore, the birth-rate, the abortion-rate, the infantile mortality-rate, the marriage-rate, and the age at marriage all have to be considered. But since it has been shown that differences in the amount of marriage and in infantile mortality (so far as contributions to the next generation are concerned) are not so important as are differences in the birth-rate itself, and further, that differences in the number of children born to married women irrespective of age are of more importance than are differences in age at marriage, it is possible to disregard all else but differences in the actual birth-rate, and to seek reasons other than the marriage-rate and the age at marriage in order to explain the fact that, on the average, the wealthy, the cultured, and the socially eminent make distinctly smaller contributions to the next generation than do their opposites.

A social class can continue only through reproduction or else through reinforcement from without. So long as the State continues to regard the middle-class as a desirable constituent of its population, so long must parentage on the part of its membery

* The Social Selection of Human Fertility: the Herbert Spencer Lecture delivered at Oxford, 8 June 1932. By Dr. ... 32. (Oxford: Clarendon Press; London: Oxf... 1932.) 2s. net.

regarded as a social service. It appears, however, that the supply of children by this middle-class (which constitutes some 10-15 per cent of the total population) is sufficient only to replace one-half of the present parental generation. It is the case that the class is being reinforced continually by such as ascend to it from the less affluent social strata, but it has not yet been shown that the calibre of these reinforcements equals that of those whose company they join. It can be argued that the middle-class is the product of a very intensive selective process, that it created itself during the eighteenth and nineteenth centuries, its families usually having had their origin in individuals who wrenched themselves free from some harsh environment and gained social promotion in their own time through the exhibition of their own talents. It would seem that such as could exhibit abundant enterprise, thrift, and foresight were able, in those days, to attain a certain level of affluence, and that these were the founders of the middle-class.

This class is only worth saving if the qualities which distinguish it are socially desirable and are in any degree the peculiar true-breeding properties of the class. It is by no means improbable that this class has, through selection, come to be somewhat differentiated in certain respects from the general body of the population from which it sprang and from which it is recruited. Possibly it is not without significance that the children of this class are to be distinguished from those of others by differences in the intelligence quotient. Furthermore, though one should be accused of bias, it is possible to hold the view that in respect of perseverance, of ambition, of æsthetic taste, of grasp of moral principle—the very qualities that make for good citizenship—this class and its members are exceptionally well endowed.

If this be so, then it would seem that through a low reproductive rate the spread of these qualities is becoming more and more restricted with each successive generation. In this there is furnished a major problem awaiting the attention of the serious statesman. The problem would seem to be that of dissociating a low reproductive rate on one hand and the estimable qualities that make for good citizenship on the other. At the present time, and in the existing social system, it is an obvious fact, recognised by all, that it is a distinct advantage to the individual so to choose his parents that he is ither an only child or else one of two; for in these stances he can expect to be better tended, ated, and secure a better financial e chosen competitive professional career, and thus more quickly obtain that social promotion which is so universally desired than can one of a family of five to ten. To choose parents of low fertility is to choose not only one's parents but also one's environment—plentiful food, ample shelter, rest, and attractive recreation.

Infertility has an economic value, and social promotion is favoured by a low reproductive rate. In all ranks of society, infertility, whether pathological in its causes or the result of deliberate voluntary choice, endows its possessor with definite social advantages. The question to be asked and answered is this: *Is relative infertility a cause of social success, or is it a consequence? Must one be sterile to be socially successful, or does success bring sterility in its train?* Dr. R. A. Fisher, in the Herbert Spencer Lecture recently delivered at Oxford, deals with this question. The subject of his lecture was "The Social Selection of Human Fertility", and it is an attempt to create a substructure for eugenic optimism out of the genetics of populations. He presupposes that the qualities which have made for success within the social organisation that has existed during the last two hundred years in Great Britain are genetic, and is of the opinion that social promotion is gained through the expression of characters which make for useful citizenship. He makes out a very strong case for the adoption by the State of a system of family allowances. It is shown that such a system provides no economic motive either for having children or for refraining from having them, but that it merely abolishes the economic bonus for childlessness and permits parents to regulate their reproductive rates.

It is not generally recognised that a family endowment system already exists in Great Britain, but that the allowances are paid only to children of the unemployed and to those who are in receipt of poor relief. It is the case that a man with a sufficiently large family in certain of the occupational groups is actually better off when unemployed than when in employment. It is indeed provocative of thought to note that if two couples are compared, one of them childless and the other with four children, but both receiving the same income for equivalent social services, their effective incomes available for personal expenditure and savings stand in the ratio of 3 : 2, the childless couple receiving a bonus amounting to one-third of their income in consequence of not having four children.

Dr. Fisher improves upon the cry of 'equal pay for equal work', for he advocates an equal standard of living for equal work. He claims that a wage including family allowances sufficient to meet the

entire cost of children would secure this end and would cut out the heavy bonus for childlessness which is an outstanding feature of the present system. In this lecture the details of accountancy which the institution of such a system would demand are not discussed, but Dr. Fisher advocates that in general the allowance payable to parents in each social grade should be proportional to the basic salary in that grade—that is to say, that the allowance should be equivalent to the actual cost in expenditure and savings incurred on the average on behalf of each child in the group.

Brief reference is made to the system of family allowances which was instituted after the War by a group of French industrialists and which is now extended to include all the wage-earning classes throughout the country. In Great Britain, the beginnings of such a scheme are seen in the establishment by Sir William Beveridge of a system of family allowances for the teaching staff of the London School of Economics. In the University of Edinburgh, parentage is made less of a burden by the fact that the children of the staff are excused class fees.

Dr. Fisher possesses all the qualifications of the really good propagandist. If he wears a professional label, it is that of the statistician; if he has a hobby, it is biology. He is a propagandist in human biology and rides his hobby in a most attractive fashion. His blandness is really dangerous; nothing is easier than to accept his views without question. However, his persuasiveness is not greater than his knowledge. If there be an alternative to this simple, lucid, concise suggestion, then it must undoubtedly come from a skilled economist who is also a confirmed bachelor.

If, as Dr. Fisher implicitly states, a system of family allowances encourages a rise in the reproductive rate, then much of the infertility of the middle-class can be nothing more than unexploited fertility—that is to say, middle-class parents could readily have more children if they should so choose. This controlled fertility may result from the habitual use of contraceptives, or, as seems more probable, it may be due to the fact that in this class the frequency of sexual intercourse is relatively low. It appears that a child that is not a burden is quickly conceived. If this is the case, if, in the opinion of the State, a higher reproductive rate on the part of the middle-class is to be desired, then it may well be that if and when prosperity returns the deduction from the salaries of civil servants and others which were recently made will not be restored, but instead a system of family allowances will be instituted.

It has to be recognised that the efforts of the many who wish to correct what they regard as the evils of the differential birth-rate by endeavouring, through an appeal to idealism, to induce others of their own group to beget larger families have not met, and will not meet, with any discernible success. It is quite useless offering the alternatives of the present comfort of the reproducers on one hand and the indefinitely future welfare of society in general on the other. This latter appeal possesses no strength.

It was true, and possibly is still true, that a man may be so moved by his idealism as to be willing to die for his country, but it is not to be expected that he will be equally willing to procreate in her service until he has been convinced that his children will enjoy the advantages that have meant so much to him. Economic security means more to the average man of the middle-class than does the decline of the Empire or the suicide of the race.

A Synthesis of Medieval Science

Introduction to the History of Science. By George Sarton. Vol. 2: *From Rabbi ben Ezra to Roger Bacon.* (Carnegie Institution of Washington, Publication 376.) Part 1. Pp. xxxvi + 480. Part 2. Pp. xvi + 481-1251. (Baltimore, Md.: The Williams and Wilkins Co., 1931.) 12 dollars.

THE first volume of Dr. Sarton's "Introduction to the History of Science", already reviewed in NATURE, was universally and deservedly acclaimed as a major contribution to our knowledge of the growth of civilisation. The second volume, which follows after a brief interval of four years, covers the twelfth and thirteenth centuries—or, as Dr. Sarton puts it, the period from Rabbi ben Ezra, "one of the greatest Biblical commentators of the Middle Ages", to Roger Bacon, the *Doctor Mirabilis*. There is probably no single scholar competent to subject the book to a thorough and authoritative critical analysis, but the general verdict can scarcely be other than that the author has fully maintained, and, indeed, in several notable respects, surpassed, the high and exacting standard he set himself in the first part of the work. One finds it difficult to decide whether Dr. Sarton is more to be praised for his courage in attempting so stupendous a task, or for his unflagging determination in carrying it to so successful a conclusion; it is at least certain that no future historian of science, of learning as a whole, or of civilisation itself, will consider his library a-quately equipped unless a copy of Sarton' arm's reach.

It would be an egregious mistake to regard the "Introduction" as nothing more than an elaborate, comprehensive, and conveniently arranged bibliography. Dr. Sarton's ambition—achieved with a degree of completeness that must afford him the keenest satisfaction—was to provide a framework for the study of medieval science and medieval thought, and to express as exactly as possible the state of our present knowledge on each topic. While full bibliographical references are clearly essential to such a framework, in themselves they are but the unit bricks that have to be classified, arranged, and mortared together in orderly fashion before the significance of each and of all can be appreciated. It is in this synthesis of scholarship that Dr. Sarton excels. Enthusiastic for the widest vision (but no less for accuracy in detail), he is free from that intensive predilection for any particular period or problem which, necessary and laudable in other circumstances, would seriously disturb the balance of such a scheme of integration as is undertaken in this book. As a consequence of his catholicity of interest, he has been able to maintain, between the divers and manifold aspects of the medieval corpus of knowledge, an equilibrium that even the most narrow specialist must recognise to be just.

Yet we fancy that many specialists will be astonished at the intimate acquaintance that Dr. Sarton shows with the recondite details of their particular fields. Such a trivial question, for example, as the suggested identification of the Latin writer Artephius with the poet and vizier Al-Tughra'i does not escape him, while a host of similar instances might be adduced to prove that his conscientiousness has extended into every section and every subject. His picture of medieval learning, indeed, is not the work of a poster artist, or even of an impressionist; it shows rather the Pre-Raphaelite characteristic of minute accuracy in detail, and if the minutiæ do not unduly obtrude themselves, it is because the broad features of the canvas are too truly designed and too skilfully limned. This dual excellence is rarely found in such perfection as in Dr. Sarton's book, where the reader desirous of a bird's-eye view of wide stretches of territory will find equal satisfaction with the scholar who seeks specific information upon some individual point.

Of the twelfth century, Dr. Sarton remarks that it was essentially a period of transition and compromise, when exchanges between the three main civilisations of Europe and the Mediterranean world —the Jewish, the Christian, and the Muslim—were [illegible] than they had ever been before. The [illegible]on from Arabic into Latin was fervently undertaken by scores of accomplished and indefatigable men—Gerard of Cremona alone translated nearly a hundred treatises, some of them of immense size—and the foundations of a new, composite, Greco-Arabic-Latin culture were laid down. In mathematics, the use of Hindu numerals was introduced, and Muslim algebra was transmitted to the West by the efforts of such men as Adelard of Bath, John of Seville, and Robert of Chester. The first Latin translation of Euclid—also from the Arabic—was made about 1142, while in 1149 the trigonometrical tables of Al-Battani and Al-Zarqali were adapted, for astronomical purposes, to the coordinates of London. The Almagest of Ptolemy was available in Latin by 1172; fifteen years later Jabir ibn Aflah's "Correction of the Almagest" was added—again by Gerard of Cremona—and although a flood of astrological treatises simultaneously deluged the Latin West, it was in the twelfth century that European astronomy showed its first real activity since the days of classical Greece.

Chemistry, in the guise of alchemy, was another twelfth century importation from Islam, and by the end of the century original treatises were beginning to appear. Dr. Sarton places Geber's "Sum of Perfection" towards the end of the thirteenth century, but it is more probably to be regarded as the culminating point of the previous century's alchemical acquirements. Physics, geography, and natural history shared in the general reawakening of learning, while medicine benefited by the translations of Hippocrates and Galen, among the Greek authors, and of Rhazes, Avicenna, Al-Zahrawi, and Ibn al-Wafid (Abenguefit) among the Muslims.

By the middle of the thirteenth century the intellectual centre of the world had definitely moved. Islam and Israel were still doing a large share of the work, but Christian scholarship had at length established that preponderance which was only to increase with the passage of time. In the second half of the century "the hegemony of Christendom . . . was absolutely indisputable". Baghdad was sacked by the Mongols in 1258, and though the culture of Islam was not thereby completely destroyed, it nevertheless suffered a grievous blow. The Jews were nearly everywhere reduced to minor importance, and almost ceased to have international significance in the world of learning. Finally, this "time of Roger Bacon, of Jacob ben Mahir ibn Tibbon, and of Qutb al-Din al-Shirazi" marked the triumph of Aristotelianism in the form of Thomist philosophy.

It is not surprising that Dr. Sarton has selected Bacon as one of his eponymous heroes for chrono-

logical characterisation. "Bacon", he says, "was essentially an encyclopædist; that is, he was tormented with the idea of the unity of knowledge, and his life was a long effort better to grasp and to explain that unity." Shall we substitute 'Sarton' for 'Bacon'? Then the truth of the statement is in no wise diminished. E. J. Holmyard.

Australian and New Zealand Ornithology

(1) *What Bird is That? a Guide to the Birds of Australia.* By Neville W. Cayley. Second edition. Pp. xx + 319 + 44 plates. (Sydney: Angus and Robertson, Ltd.; London: The Australian Book Co., 1931.) 12*s.* 6*d.*

(2) *New Zealand Birds.* By W. R. B. Oliver. Pp. viii + 541 + 6 plates. (Wellington, N.Z.: Fine Arts (N.Z.), Ltd., 1930.) 30*s.*

(1) Australian ornithological workers have been very active during this century. Campbell opened in 1901 with his book on the "Nest and Eggs"; this was followed (1901–14) by a much larger work by North on the same subject, which also included the descriptions of the birds. In 1906, Hall issued a second edition of his "Key" of 1899; this edition was illustrated by photographs of the birds, taken from Gould's folio work. This led up to the famous "Australian Bird Book" by J. A. Leach, which ran into seven editions. Leach gave a small reproduction in black and white of all the birds, and a few coloured plates depicting in miniature many forms, of which nine went to a full plate.

In this present volume, Mr. Cayley, an artist, has drawn coloured figures of all the birds of Australia and these have been reproduced in the best style, thus enabling a student to identify any bird seen on a ramble by the water or inland. This book can be called the 'big brother' of the "Australian Bird Book", but the colour process of reproducing the plates has much improved since the latter was published and Cayley's plates are admirable.

We learn from Cayley's book that it was sponsored by the Gould League of Bird Lovers to celebrate the coming of age of that useful society. The purpose of this volume is to assist and encourage those Nature lovers who desire to gain a more intimate knowledge of the birds of Australia.

The work is divided into four main sections: forest-frequenting birds; birds of the heath-lands and open country; birds of the lakes, streams, and swamps; and birds of the ocean and shore. These are again divided into small groups, such as birds of the brushes and big scrubs, birds of the open forest, etc.

Finding ourselves in any type of country and seeing a bird unknown to us, we turn up our book to the chapter dealing with the kind of territory we occupy: there we find a coloured plate depicting the birds of that region. Having identified our picture and noting its number, we turn to that number in the letterpress, where we find the name of the bird, its distribution, notes on its habits and a description of its nest and eggs, and the months of the year when the eggs are to be found. Thus we are able to answer the oft-repeated question: What bird is that?

On p. 32 we find the only subspecies admitted, and that a new one, a form of masked owl, called *Tyto novæhollandiæ troughtoni*, a cave-dweller in that part of Australia where trees are absent, called Nullarbor Plain, to emphasise the fact. We doubt the wisdom of describing a new bird in this kind of book, especially as there are so many journals devoted to ornithology, which the compiler of the *Zoological Record* must examine. On p. 197 we find the genus *Emblema* superseded by *Cayleyna* with no explanation, and as this is the first time we have come across this word, we wonder why. We know *Emblemus* of Dejean, 1821, but here it is a nude name; perhaps it was quickened before 1842.

The author claims his volume to be "a Guide to the Birds of Australia". This it certainly is, and if we can answer the question on the title-page he can be satisfied that he has fulfilled his mission. The nomenclature followed is modern, as is the English name of each bird. The printing and paper are good, and the coloured plates leave little or no room for improvement. In the appendix, eleven introduced birds are treated, and the index of twenty-three pages seems complete.

This volume is a good example of the 'evolution' of a bird book. It will be rather difficult for a successor to think of the next 'stage' in development of a popular work. The size of the volume renders it easy to carry with us on our journeys.

(2) New Zealand! What visions of far-away places the name brings before us, and of tattoo-faced Maoris, savage and cannibalistic, at times; a fierce warrior race, but always an honourable foe. New-comers, comparatively speaking, to this paradise in the Pacific, from the 'Islands of Unknown', they landed in five differ- and settled in both North and S

and, 'tis said, devoured the original inhabitants. They also exterminated the large struthious birds known as 'moas'.

Our vision goes back to Tasman the Dutchman, who after discovering Tasmania, in the middle of the seventeenth century, sailed on east, and on Dec. 13, 1642, discovered New Zealand and named it after a small, flat province in Holland. This explorer never landed, for when he sent a boat off to obtain fresh water the Maoris killed some of his men, so he sailed north, to discover the Friendly Islands. About this time we have reason to believe that the moas had not long become extinct —indeed, some may have lingered on into the seventeenth century.

Now we come to the voyage of Capt. Cook, who was the first white man to land on the island; he, too, at first met with hostility from the Maoris, in Poverty Bay, in October 1769. On his second voyage, however, Cook had with him the Forsters (father and son) and Dr. Sparrman. These men collected birds at Dusky Sound, and that was the beginning of New Zealand ornithology. The sea birds collected on the first voyage are common to both Australia and New Zealand. Then we have the French landing from the *Coquille*, the *Astrolabe*, and this latter ship again with the *Zelee*; Gray, who did the birds in Dieffenbach's "New Zealand", 1844, as well as in the account of the *Erebus* and *Terror*, the bird parts of which were published in 1844–45; then Peale, whose work was published in 1848; thus leading up to Buller's "Birds of New Zealand", 1872–73, the second edition in 1888 and the supplement in 1905–6. In this work are the observations of Potts, who probably did more than any other observer in New Zealand to complete the life histories of the birds. In the New Zealand avifauna is included that of the Kermadec Islands and the Chatham and Antipodes Islands. This brings us to the book under review, Oliver's useful volume, a complete and up-to-date work, of which every ornithologist should possess a copy.

In the beginning we have a history of ornithology in the islands; chapters on the ecology, migration, changes in the fauna; the economic value of birds, and on the classification. This is followed by a history of the moas, leading to all the known forms, copiously illustrated with photographs of the heads and sterna.

Then we come to the living birds, all of which are carefully worked up in the modern method. ... orders, families, and genera are discussed, ... the species, of which a full history is ... bird described, its affinities and ... mutants, if any, given; the nestling and egg are described where known, and the breeding season indicated. Then follow the distribution, habits, food, voice, and breeding habits, and its relation to man.

The list of birds thus treated, of purely New Zealand forms, is 230, excluding the moas and introduced birds. All through the work, the extinct birds are given their place, as well as those birds introduced from Australia, etc. A complete index is added.

At the end of the book, about fifteen European, one Indian, and two Australian birds are also treated in the same way as those in the body of the work. Most people will regret the introduced birds, as in so many cases they depose the native-born and may eventually become harmful.

The new forms described are *Pachyptila turtur fallai*, *Cyanoramphus novæzelandiæ chathamensis*, *Bowdleria punctata stewartiana*, *Prosthernadera novæseelandiæ chathamensis*. This last form was described by Dr. E. Hartert two years before, under the same name. Amongst the extinct forms we find a new family, Anomalopterygidæ; a new genus, *Pachydytes*, and two species of extinct penguins, *P. ponderosus* and *P. novæzealandiæ*; and new genus and species, *Euryanus finschi*, for the extinct New Zealand teal. To the list of the birds of New Zealand must now be added *Sterna macrura*, the arctic tern; *Pisobia melanotos*, the pectoral sandpiper; *Crocethia alba*, the sanderling; *Lobipes lobatus*, the northern phalarope; *Microtribonyx ventralis*, the black-tailed water-hen; *Threskiornis molucca*, the white ibis (Australian); and *Graucalus novæhollandiæ*, the black-faced cuckoo shrike.

G. M. MATHEWS.

Italian Fisheries

Ministero dell' Agricoltura e delle Foreste: Direzione-Generale dell' Agricoltura. La pesca nei mari e nelle acque interne d' Italia: notiziario tecnico e legislativo e repertorio della industria e del commercio dei prodotti pescherecci. Vol. 1. Pp. xvi + 356. Vol. 2. Pp. x + 710. Vol. 3. Pp. ix + 412. (Roma: Istituto Poligrafico dello Stato, 1931.) 3 vols., 100 lire.

FASCIST Italy has been quick to recognise that in its fisheries, no less than in any other branch of the nation's commerce, future progress depends upon the efficiency with which the industry is conducted. As an initial step towards rationalisation, therefore, an exhaustive survey of the fisheries situation in all its phases has been under-

taken, in which no relevant subject appears to have been overlooked. Testimony to the thoroughness of this official 'stock-taking' is provided by these three remarkable volumes recently issued by the Italian Ministry of Agriculture and Forestry, the government department responsible for the administration of the fisheries. It is impossible here to give more than a bare indication of the contents of the three volumes, which comprise nearly 1500 pages of text, accompanied by a wealth of photographs, diagrams, charts, and plates, both coloured and uncoloured.

Vol. 1 commences with a descriptive catalogue of the various institutions and corporate associations which are directly interested in fisheries matters, whether these be scientific institutions such as marine laboratories and fish-hatcheries, schools, museums, and learned societies, or industrial syndicates, either national or local. Not the least instructive part of this section is the grouping of the different institutions and associations in relation to the particular department of the government to which they appear to be responsible. The second part of vol. 1 is devoted to the laws governing national fishing, and to the international conventions honoured by the State.

Vol. 2 is a detailed treatise on fishing technique. Beginning with the sea fisheries, descriptions and illustrations (many coloured) of the exploited fishes, crustaceans, and molluscs are first given, and then follows a most interesting and detailed account of fishing methods and results. In this volume, the charm which old-time methods of fishing excite is unusually evident because of the rich variety in boats and gear used in the Italian sail fishery. Nevertheless, this does not detract from the interest aroused by the description of the more modern if more prosaic steam fishery. Leaving the sea and turning to the fresh water, the subject matter is very complete.

The third volume is concerned with the marketing of fishery products, either as fresh commodities or after some form of conservation. Of the three volumes, this one is the most domestic, in that it deals with matters which are more the concern of the home government and the fishing industry than of the lay reader outside Italy. Yet it demonstrates in a very simple way the thoroughness with which the survey has been conducted. Thus, more than seventy pages are devoted to an enumeration of the common names used at different places for the economically valuable fishes, in order, it is assumed, to leave no room for doubt on account of local differences. In many instances, indeed, the common name, dialect name, and scientific name are given for one and the same locality. Or again, whereas it would not have been an unusual procedure if the volume gave estimates of the number of fish merchants, salesmen, boatbuilders, and personnel of other ancillary occupations, it is noteworthy that *individual* merchants and salesmen, etc., are named and classified according to the locality in which they are operating.

Altogether, this 'blue-book' on the Italian fisheries—for such is the most appropriate description of it—is a publication of a character almost unique, in that it is a State guide to the fisheries, prepared by a government, lavishly illustrated, and printed in the State Printing House. The work which it most closely resembles is the great "Handbuch der Seefischerei Nordeuropas" published in Germany, to which, it must be confessed, nationals of Great Britain must refer for the most complete description of British fishing. Certainly there is no comprehensive account of our fisheries written in English which can claim to be equivalent to either the Italian or German works. E. Ford.

The Internal Combustion Engine

The Internal Combustion Engine. By D. R. Pye. (Oxford Engineering Science Series.) Pp. xii + 250. (Oxford: Clarendon Press; London: Oxford University Press, 1931.) 15*s*. net.

Under this heading, two books on internal combustion engines, one by Prof. W. E. Dalby and the other by Mr. H. R. Ricardo, were recently reviewed in these columns (Nature, Nov. 28, 1931, p. 886). Mr. Pye's book differs considerably from either of these in scope and outlook. It is a very complete monograph on the theory of the engine. It is written in the clear and attractive style which those who are familiar with Mr. Pye's previous writings have learned to expect from him. The author deals fully with the practical nature and the comparative efficiency of combustion at 'constant volume' and 'constant pressure'; the nature of fuels; detonation; combustion in the cylinder; and the effect of various factors on thermal efficiency. There is a final useful chapter on the testing of engines. There is no unnecessary matter in the book, which undoubtedly presents the fullest and at the same time most concise description of the theory of the engine so far as it has been developed by modern research. Mr. Pye naturally draws most of his illustrations of the theory from the results of his own experience with high engines; he does not touch on the

problems of slow-running engines, but the underlying theory is common to all types.

There is little in the book to which a critic could take exception. Perhaps too much value is attached to the measurement of the air consumption of engines. When the fuel is largely or mainly composed of hydrocarbons, whether gaseous or liquid, there is a point at which the consumption of air per horse power developed is a minimum. This point occurs when the mixture is rich, that is, when there is too much fuel for complete combustion. Over a wide range of mixtures the air consumption per horse power remains practically constant, so it is comparatively easy to measure accurately in practice. The minimum air consumption gives a measure of the overall efficiency of the engine, but it does not give a measure of the minimum fuel consumption of the engine, or of the amount of fuel that may be lost by imperfect distribution in a multi-cylinder engine. Mr. Pye, following Mr. Ricardo, assumes that it does, and arrives (on p. 135) at certain conclusions which appear to the reviewer to be wrong, although perhaps not far wrong. But it is accidental that they are not far wrong. Again (p. 154), in the course of a general discussion on thermal efficiency referred to fuel or air, it is not strictly true to say that in gas engines operating on carbon monoxide or hydrogen, the heat output and the efficiency is the same for a mixture containing 80 per cent of the gas required for complete combustion as for a mixture containing 80 per cent of the air required.

These, however, are minor blemishes in a first-class work, which has been needed for some time; it can be strongly recommended to all serious students of the subject, and particularly to those who are engaged in unravelling some of the many properties of the internal combustion engine that are still imperfectly understood. It is unfortunate that the price of the book will prevent its purchase by many who would gain by having it on their shelves, but this is a general criticism applying to most scientific books.

Colloidal Properties of Smokes

Smoke: a Study of Aerial Disperse Systems. By Prof. R. Whytlaw-Gray and H. S. Patterson. Pp. viii + 192 + 12 plates. (London: Edward Arnold and Co., 1932.) 14*s*. net.

IN this book the authors give a connected account of the large body of work on disperse systems which they have for some years been carrying together with the relevant researches of other investigators. The subject is one of considerable theoretical and practical interest. On the theoretical side, the contrast in properties between a substance dispersed in a liquid medium and one dispersed in a gas throws light on the mechanism of general processes in sols, such as that of coagulation; on the practical side, the coagulation of smokes assumes particular importance in the industrial precipitation of fumes and in the consideration of urban fogs; while as an example of the bearing of the subject on the world of atomic physics, we may quote the experiments of Ehrenhaft on the sub-electron, the fallacious conclusions of which our authors trace to a neglect of the processes of coagulation common to all smokes.

The technique of all observations on smokes—counts of particles, size of particles, density of particles, to quote some of the most important—is a difficult one, and, very wisely, much of the space is devoted to a discussion of the experimental methods by which the authors have been enabled to obtain reproducible smokes and consistent measurements. The particular ultra-microscopic method by which certain earlier errors of counting have been eliminated is described in detail, as well as other methods by which it has been checked. Very ingenious is the way in which the velocity of fall under gravity, combined with the velocity of rise of the charged particle in a known electric field, has been used to determine the density of the particles; it is, of course, reminiscent of Millikan's method of determining e, but in this case e is taken as known, within an integral multiple, which is in its turn determined by carrying out four or five experiments, and selecting integers which give a consistent result. Some of the results of this method are very striking. It is, perhaps, only to be expected that the density of the solid particles should be very much below the bulk density of the substance in question, but, turning to liquids, whereas with oil droplets the density comes out in good agreement with the bulk density of oil, for mercury droplets the observed particle density is about 1·7. The reason for this the authors do not discuss.

While it is shown that Smoluchowski's theory of coagulation in liquid media can be adapted to give a good account of the very careful measurements of coagulation of smokes carried out by the authors, many of the problems described in this book are still in the early stages of investigation rather than in the stage of final solution. The movement of the particles under the influence of light, known as photophoresis, is still, when it comes to the point, quite obscure: the electrification of smokes, as

the authors point out, needs much further work before the distribution of charge with particles of different substances, and different methods of production, can be tolerably understood. A very sound beginning has, however, been made, and it is not the least merit of the book that, while what has been achieved is soberly set down, no attempt is made to gloss over the very grave difficulties still to be met in many parts of the subject.

E. N. DA C. A.

Short Reviews

Handbuch der Experimentalphysik. Herausgegeben von W. Wien und F. Harms. Unter Mitarbeit von H. Lenz. Band 25: *Geophysik.* Teil 2: *Physik des festen Erdkorpers und des Meeres.* Unter der Redaktion von G. Angenheister. Pp. xiv + 823. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1931.) 74 gold marks.

THIS book is good in places. Prof. Tammann discusses geochemistry. His article contains a needed warning against the too ready acceptance of the hypothesis of a sulphide shell of considerable thickness. On the other hand, he asserts that there is a critical pressure, above which the melting point decreases with pressure, and makes no mention of Bridgman's criticism of this hypothesis. G. Kirsch deals with radioactivity, age determinations, and heat supply, on the whole well, but gives on p. 51 a misleadingly incomplete statement of the nature of Jeffreys's objections to the theory of periodic melting. Kossmat's article on tectonics is useful and critical, though too short for the subject, and there is a shortage of quantitative data on the topics discussed.

The figure of the earth is treated by Schmehl; this article is notable for a correct statement of Stokes's formula, which has been misquoted in several recent German works. This section and that of K. Jung on the interpretation of gravity variation are uniformly good. E. Tams gives a good account of the distribution of earthquakes in place and time, and O. Meisser of the theory of elastic waves. Krumbach's article on seismology, however, shows some serious omissions. There is no mention of the Milne-Shaw seismograph, with which so many observatories are now equipped. In dealing with dispersion of surface waves, there is no mention of the distinction between wave-velocity and group-velocity, or of the important work of Stoneley and Tillotson. On p. 520 the author makes the surprising statement that Jeffreys agrees with S. Mohorovičić and Gutenberg that the thickness of the upper layer is 40 km., though there is a correct, but incomplete, reference to one of the papers in which Jeffreys estimated it as about 12 km.

The articles on oceanography, by Defant, and on tides, by Hopfner, are excellent summaries of existing knowledge, including recent British and American work.

The index shows lack of care. Three references to J. C. Adams should be to L. H. Adams, and "R. L. Lawson" covers the identities of A. C. Lawson and R. W. Lawson. Some reluctance to believe that a Christian name can begin with the letter I has affected the references to Newton, Bromwich, Taylor, and Lehmann; and H.M.S. *Challenger* seems to be thought to be a person. Several other authors have their names misspelt or wrong initials given.

H. J.

Vital Records in the Tropics. By P. Granville Edge. Pp. xi + 167. (London: George Routledge and Sons, Ltd., 1932.) 7s. 6d. net.

THIS little book may be recommended with confidence to the consideration of medical officers, administrators, and officials in tropical countries whose duties bring them in contact with a backward indigenous population. The case for the record of vital statistics is argued convincingly but temperately, and, as appears, with a full appreciation of the difficulties involved.

When dealing with methods of obtaining and recording statistical material, the author warns his readers that the trials of the recording officer go far beyond the suspicion, indifference, or stupidity which hamper, for example, the census among the civilised illiterate. These elements are indeed present, but to them must be added the effects of exaggerated rumour, taboos, social regulations, and an unlimited number of magical and religious concepts and prohibitions. It is made abundantly clear that the census officer and vital statistician must know something more than a smattering of anthropology and the bearing of anthropological data on his work, if his duties are not to lead him into trouble. At the same time he must be an acute judge of native character in the individual, in order that he may keep a check on the idiosyncrasies of his native assistants.

It is in view of these difficulties that the author, wisely it would seem, favours, at least in the initial stages, "small scale inquiries", that is, the intensive investigation and detailed record of single units (in native social organisation), of which the results can afterwards be combined in larger and larger unities until the frontiers are ultimately reached. The difficulties due to migratory habits of the native, whether normal or in an emergency, such as illness, are noted, and certain remedial measures suggested; but the author deals with a village population only, and does not indicate a method of approach when a population is nomadic, as, for example, the Masai.

Handbuch der Geophysik. Herausgegeben von Prof. Dr. B. Gutenberg. Band 1, Lieferung 1. Pp. vii + 308. 54 gold marks. Band 2, Lieferung 1. Pp. viii + 564. 102 gold marks. Band 3, Lieferung 1. Pp. ix + 570. 64 gold marks. Band 6, Lieferung 1. Pp. v + 312. 63 gold marks. (Berlin: Gebrüder Borntraeger, 1930–1931.)

FOUR more sections of this learned work by numerous authors are now available. It would [illegible] easy to find defects in it, but it would [illegible] difficult to do it better. What strik[illegible]

particularly is the inevitable fact that, in a comprehensive work of this character, sections are liable to become out of date owing to later work while the book is in the press; and most of the faults that one might find would be of this nature.

Prof. Nölke gives a thoughtful account of theories of the origin of the solar system, but does not appear to have grasped the essential difficulty of explaining how the comparatively small masses of the planets succeeded in holding themselves together for a long enough time to be able to condense. In places also he seems to have misunderstood the work of other investigators. Berg, writing on geochemistry, supports the eclogite-sulphide constitution of the rocky shell, but Gutenberg himself seems to agree with the reviewer that the evidence is in favour of dunite. Other chapters deal with the figure of the earth, its age, geological history, thermal history, igneous activity, movements of the crust, effects of ice, and geophysical prospecting.

Special mention may be made of Gutenberg's theory of continental spreading. He admits the force of the mechanical objections to continental drift as usually understood, but notices that the weight of continents implies shearing stresses within them of the order of magnitude of the strength, and consequently supposes that they may have spread out under their own weight. H. J.

Business and Science: being Collected Papers read to the Department of Industrial Co-operation at the Centenary Meeting of the British Association for the Advancement of Science, London, September 1931. Edited by R. J. Mackay. Published by Authority of the Council of the British Association for the Council of the Management Research Groups of Great Britain. Pp. xvi + 312. (London: The Sylvan Press (Henderson and Spalding, Ltd.), 1932.) 5*s*.

The various papers collected in this volume form a valuable contribution to the study of problems of management. Mr. B. Seebohm Rowntree points out in a foreword that good management is the most important and most dependable factor in the prosperity of a business. He emphasises that business management is a complicated science which must be studied as laboriously as one studies chemistry, medicine, or engineering, and on the extent to which individual employers succeed in mastering that science will depend not only the prosperity of their own firms but also that of the nation to which they belong.

The field covered by the papers is very wide, and includes contributions from some forty speakers, grouped into five sections, entitled "The Study of Management", "Preparation for Management", "Body and Mind at Work", "Some Higher Management Problems", and "The Development of Invention". In the section "Preparation for Management" an interesting account is given of various educational institutions which aim at providing training for the higher administrative posts [in] industry. Viscount Leverhulme describes the [Tra]ining College and the 'Trainee System' [of Leve]r Brothers; M. Pierre Jolly explains the methods adopted at the Business Preparation Centre recently inaugurated by the Paris Chamber of Commerce, of which a special feature has been the establishment of a bureau to collect and prepare materials drawn from actual business problems to be used as 'cases' for demonstrating to students the application of theoretical principles to practice; Dr. Bowie details the methods adopted in the College of Technology, Manchester, where the first Department of Industrial Administration was established in Great Britain; Prof. Florence describes the commerce course of the University of Birmingham, while Prof. McNair tells of the work carried out at the Graduate School of Business Administration, Harvard University.

Sexual Life in Ancient Greece. By Hans Licht. Translated by J. H. Freese. Edited by L. H. Dawson. Pp. xv + 557 + 32 plates. (London: George Routledge and Sons, Ltd., 1932.) 42*s*. net.

The late Dr. Licht's study of the sexual life of the Greeks of antiquity is a marvel of erudition. He ransacked Greek literature from end to end—from Homer to the latest writers in the Greek tradition of the beginning of the Middle Ages—and there is no side of eroticism to which any reference is made that he did not bring under review. The attitude of the Greeks towards the human body, their clothing, their marriages, the place of sex in festivals and games, in the theatre, and in religion are demonstrated by reference to, or quotation from, their own statements; while sexual activities in the relations between men and women, prostitution, homosexuality, and a variety of other matters pertaining to sex are described in detail on the basis of material from the same source.

Although it must be admitted that sensuality in the broader and original sense played a large part in the life of the Greeks, it may seem that Dr. Licht is inclined to attach too much importance to eroticism. He regards it as "the prime cause of old Greek culture and the centre of Hellenic life". It is easy to attach too much weight to their frank admission of certain facts. Dr. Licht is also inclined to misinterpret the reticence of classical studies on these matters. The facts were recognised, at any rate in more recent scholarship, if not treated with the minuteness and particularity of the present study.

A History of Later Greek Literature: from the Death of Alexander in 323 B.C. to the Death of Justinian in 565 A.D. By Prof. F. A. Wright. Pp. xi + 415. (London: George Routledge and Sons, Ltd., 1932.) 18*s*. net.

This most helpful compendium of the later Greek literature seems to us to throw much light on the intellectual atmosphere of the period covered. The Alexandrian school of philosophers and scientific workers, such as Euclid, Aristarchus, Archimedes, Eratosthenes, and Hipparchus, is given all the prominence it deserves. It is, however, the prose writers and poets who interest the author most; and the quotations he gives from their works add to the value of his criticisms. T. G.

Scientific Research and Industrial Development

IT is difficult if not impossible to appreciate the potentialities of science in industry or in society, or to assess accurately any plan which science can offer us, apart from the consideration of the relations between science and industry which have developed in the past and as they exist to-day. Nor is this a simple task of history. It is immensely complicated by the dynamic character of both science and industry. Society itself does not change its aspects more completely or rapidly than science or industry under the impact of science. For this reason prediction as to the results of planning industry or society on scientific lines is extremely rash. All that can be said is that the scientific method offers a reasonable chance of arriving at an unprejudiced solution of many of our problems and that its technique is sufficiently elastic to be adapted to the solution of new problems as they arise.

The most rapid review of the relations between industry and science during the last century provides convincing evidence of the power of science to assist in the development of industry and the amelioration of society. Of this there are few more striking examples to be found than in the field of fuel economy. A century ago Great Britain was passing through a depression fully comparable with that of the past two years and probably involving even more acute distress. The outlook in the coal and iron industries was gloomy in the extreme, yet at that very time the researches of Michael Faraday on electromagnetic induction were preparing the way for the immense development of the electrical engineering industries with their many branches to-day. The scientific discovery of the production of electric current by mechanical rotation in a magnetic field is the germ from which the dynamo and through it all the numerous branches of electrical power and electric light have sprung. Simultaneously, the engineer was applying his science to the development of railway transport and the advantages of gas lighting were slowly spreading over the country from London and the larger cities.

All these developments themselves induced large demands for coal and iron and finally steel, but as Prof. W. A. Bone pointed out in a recent brilliant lecture, it was the continuous application of scientific methods in the utilisation of fuel that made for progress. James B. Neilson's invention of the hot blast in iron smelting, Whitwell's development of the regenerative principle in blast furnaces, Bessemer's and Thomas and Gilchrist's discoveries in steel making, the Siemens gas-fired open hearth regenerative furnaces—these were all advances in economic production based upon the application of scientific principles to the daily problems of industry, and often upon a scientific study of fundamental laws of heat exchange economy or the complex chemical reactions occurring in the furnace, such as Lowthian Bell carried out for blast furnaces. The gas and coke industries show a continuous record of expansion which is inextricably linked with scientific method and discovery; the Bunsen burner, the Welsbach incandescent mantle, incandescent surface combustion, are all examples of independent scientific discoveries the utilisation of which has profoundly affected the development of the industry.

Similarly in power production the scientific work of Carnot, the experimental researches of Joule, the thermodynamic work of Clausius, Rankine, and Thomson led to the evolution of a scientific theory of the steam engine on which later developments were based. Sir Charles Parsons' invention and development of the steam turbine, perhaps the greatest mechanical achievement of the century, cannot be separated from scientific method and its application to industrial problems. The internal efficiency of the turbine itself has since been increased by the scientific study of nozzles, 'bleeding' and the use of higher velocity ratios, while other scientific work with higher boiler pressures, higher vacuum in the condenser, superheating, regenerative 'cascade' fuel-heating, etc., has increased the thermodynamical efficiency of the cycle. Nor have these achievements exhausted the possibilities. It is probable that the opportunities for pioneering in this field for the next generation are as great as ever; much yet remains to be done, particularly in extending scientific control in the utilisation of fuel, which incidentally lies at the root of the smoke abatement problem.

In spite, however, of the convincing demonstration in the past of the power of scientific investigation to alleviate the difficulties of the coal and fuel industries, a hiatus between knowledge and action persists which adds considerably to the difficulties in which the coal industry finds itself to-day. Not even the growing seriousness of atmospheric pollution or the intensity of the unemployment situation has driven Parliament to consider co-ordination in the utilisation of our coal resources in the form of smokeless fuel or oil fuel as a possible economic policy worthy of development. The fuel problem and the competition between raw coal, gas, and electricity is still allowed to develop along haphazard lines, without any attempt to plan and enact a scientific and economic national policy. To this position no contrast could be more startling than the discussion on fuel subjects at the jubilee meetings last year of the Society of Chemical Industry, which was planned to elucidate definite answers to such questions as the probable effect upon the amount of coal raised of the increasing use of oil, of the future development of the gas and electrical industries, of a large development of low-temperature carbonisation, or of a general improvement of the standard of living.

Only upon the considered answers to such questions can an adequate fuel policy be based, yet here again it is science and industry and not P[illegible] ment which is conducting the inquiry. [illegible] ference indeed took a sombre view of [illegible]

of any increased demand for coal, Dr. Lessing considering that a decrease in consumption is more probable; and even in the development of the hydrogenation process, prospects of an increased output of raw coal are not bright. Although international agreements might secure more lucrative prices, they are unlikely to affect the tonnage of coal raised. Lieut.-Commander Kenworthy's suggestion that scientific workers, economists, and business men should set up a representative body to examine the economic side of the coal problem was itself a confession that Parliament is not the instrument which will put the coal-mining industry on its feet. Essentially the plea was an admission that the fuel problem demands scientific treatment as an organic unit by the best brains of the country, unfettered by political ties.

In closely related industries the same story of the fundamental dependence of industrial progress upon scientific research is told. Long and patient investigations led Ludwig Mond to the discovery of nickel carbonyl, and the remarkable progress in the metallurgical industries during the last two decades is also based on purely scientific investigations—metals such as tungsten, molybdenum, vanadium being little more than curiosities when they were discovered. The 'Silal' heat-resisting alloys developed by the Cast Iron Research Association are finding a number of successful uses in industry, and it is claimed that the application of the knowledge of moulding sands and refractories acquired as a result of the Association's investigations represents an estimated saving to the industry of about £100,000 a year. Important advances in our knowledge of aluminium castings have come from the investigations of the Non-Ferrous Metals Research Association, while the investigations carried out by the British Refractories Research Association to improve the durability of refractories react on developments in the ceramic, the iron and steel, and other industries concerned with high temperature operations.

Much has been written in recent years on the dependence of the dyestuffs industry on scientific research and on the part which neglect of scientific research and development played in the decay of the British industry in the latter part of last century. It is, however, by no means generally realised that it was the rapid development of theoretical organic chemistry through the successive ideas of Berzelius, Gerhardt and Laurent, Liebig and Wohler, Dumas, unified by Cannizzaro, Williamson and Kekulé, which laid the foundations upon which the immense edifice of modern organic chemistry is based. Only in the order thus established could the significance of the fundamental discoveries, such as Perkin's mauve, the first azo dye of Peter Griess, Bayer's phthaleins and synthetic indigo, be appreciated and the development of dyestuffs, synthetic drugs, and other branches of chemical industry become possible.

These industries thus owe a double debt to science. Not only were these developments con... chemical science opening up the field ...ing some sort of order among the immensely complicated compounds of carbon, but also the fundamental discoveries leading to definite technical advances have frequently been made, often fortuitously, in scientific laboratories.

The renaissance of the British dyestuffs industry under the operation of the Dyestuffs (Import Regulation) Act is in itself a striking example of industrial development through the continuous intensive application of scientific research. Not content merely to tread in the footsteps of its foreign competitors, in 'caledon jade green', the 'duranol' colours for acetate rayon and the 'soledon' colours, the British industry has been responsible for three out of the five major discoveries in the chemistry of dyes in post-War years.

Moreover, it is interesting to note that, so far from the field being exhausted or its potentialities limited by the discoveries and developments of last century, although the main structure of organic chemistry has remained essentially unchanged during the last three decades, within that period the view that chemistry is a static science has been confounded by discoveries and industries in almost every branch of organic chemistry. The technical production of indigo essentially dates from the Deutscher Golstand Silberscheide-anstalt or Roessler sodamide fusion patent of 1901, the Sandmeyer process from indigo being still more recent. The oldest section of the dyestuffs field, the triphenylmethane or aniline colours formerly regarded as comparatively fugitive, was found in 1915 to be capable of yielding with phosphotungstic acid a series of lake or pigment colours of surprising fastness to light, whilst the azo section is still providing new dyes for overcoming the dyeing difficulties presented by the new synthetic fibres.

Closely parallel with the development of the dyestuffs industry is that of synthetic drugs and fine chemicals. Here again the industry may be traced back to much purely scientific work such as Kolbe's synthesis of salicylic acid, and its expansion has invariably been connected with external scientific work, like Knorr's discovery of antipyrine, Ehrlich's salvarsan, Fourneau's 309, Kraut's aspirin, Molle and Kleist's veronal, the isolation and synthesis of adrenaline, Banting and Best's isolation of insulin, Kendall's preparation of thyroxin and its brilliant synthesis by Harington. Pasteur's scientific investigations on yeast were prompted by a brewing difficulty and led him to the discovery of the whole theory of fermentation, the existence and action of bacteria, thence to the pasteurisation process, and finally to the discovery of the antitoxin of hydrophobia. These discoveries have not merely transformed the brewing, yeast, dairy, and cheese industries, but also have led to the rise of important new branches in the production by fermentation of solvents such as acetone and butyl alcohol. It would be difficult to measure the debt of either the fermentation industries or, indeed, of humanity to the scientific work of Pasteur.

Even in the older industries, scientific research has been responsible for revolutionary changes and developments. The art of soap-making has been

transformed into a science. Sabatier's observation of the hydrogenating properties of finely divided nickel is the germ from which has developed the industrial hydrogenation or hardening of oils and fats and innumerable processes in almost every section of organic chemistry, including the Berginisation process for obtaining liquid fuels from coal. Scientific investigations on nitrocellulose and cellulose acetate and their solvents have led to the discovery of lacquers which have not only revolutionised the paint and varnish industry, but also made possible the enormous expansion of the automobile industry. The leather substitute used extensively in upholstering motor cars has itself been produced as an outcome of the scientific investigation of nitrated cellulose. Equally important is the development of the whole rayon industry from scientific investigations and observations in the same field of cellulose—Chardonnet's discovery of nitrocellulose silk and Cross and Bevan's viscose. The technical possibilities of any one of these discoveries were scarcely dreamed of by industry when the first investigation was commenced. Finally, the great fertiliser industry, including the fixation of atmospheric nitrogen, is essentially based on Liebig's discovery of the superphosphate process and Lawes and Gilbert's patient investigations on the effect of fertilisers on plant growth.

The above brief review of the creative influence of science on industry might be extended by reference to the radio industry, which is similarly the outcome of the scientific researches of Clerk Maxwell and Hertz on the properties of the electric waves. The telephone originated with the experiments of Bell, and the cinematograph industry, the automobile, the aircraft, the synthetic ammonia industries, are all the outcome of fundamental investigations, the practical significance of which was undreamt of at the time, and each now gives employment to thousands of workers.

Admittedly, society must look to creative science for the best hope of an ultimate solution of the unemployment situation. Indirectly, therefore, the problem of unemployment is linked with the problem of fostering the most vigorous intellectual activity among scientific workers and attracting into the service of science the most able minds the present generation can provide. Conditions which tend to lower the standard of recruitment for the various branches of the profession of science may react dangerously upon the welfare of the community. If full contact is secured between the finest type of such scientific work and industry, a fertilisation of industrial research will result from which all branches of the community will benefit. So competent an observer as Prof. Henry Clay remarks in this connexion that industrial expansion takes place less as the result of the establishment of entirely new firms to exploit new processes and new demands than as a result of existing firms, which are making profits by the efficiency of their management, applying these profits to finance expansion in new directions. It would seem that only through the rationalisation of industry can creative science exert its full influence in expanding employment.

(To be continued.)

The Structure of Wind over Level Country *

ABOUT seven years ago, in connexion with the construction and navigation of airships, the Meteorological Office was called upon to conduct further investigations into certain problems of wind structure. The work was taken up with energy and ability by M. A. Giblett, the already distinguished young meteorologist who afterwards in 1930 lost his life in the ill-fated *R101*. The researches on wind structure were completed by members of the meteorological staff of the Royal Airship Works at Cardington, and the results are now issued in an impressive volume as Geophysical Memoir No. 54.

The data discussed in this memoir were derived mainly from four anemographs, three of which were set up at the corners of an equilateral triangle of 180 feet side—approximately the length of the airship *R101*—and a fourth at the middle point of one side of the triangle.

The instruments could be arranged to use recording drums turning at the normal rate, that is, once in 24 hours, or at 12 times the normal rate, or at 144 times the normal rate. A time-marking device could be set to operate simultaneously upon the individual records. The instrumental arrangements were in charge of B. C. V. Oddie; a complete description of the equipment, together with photographs and a discussion of possible instrumental errors, is given in Part I.

After that, the work falls naturally into two main branches—the facts of observation and the discussion of the observations. Parts II. and IV. contain results dealing respectively with the horizontal fluctuations in wind in time and space and with the variation of wind with height; seven appendices are devoted to the statistics, whilst the work, in all, includes no less than 95 figures, containing, in particular, reproductions of numerous records, ordinary, quick-run, and ultra-quick run. All this is a valuable store of information which probably will afford material for the discussion of further problems. The discussion in this work is contained mainly in Parts III. and V.

In Part III., C. S. Durst outlines an attractive theory of eddies. The gusts, lulls, and changes of direction in an air current are commonly ascribed to more or less circular eddies embedded in the general flow, but in the study of the ultra-quick runs it has been noted that "the wind velo[illegible] does not change regularly backwards and [illegible] between gusts and lulls, but that the [illegible]

* Geophysical Memoir No. 54. By the late M. A. Giblett (Superintendent of the Airship Division of the Meteorological Office), and other Members of the Staff of the Office. Pp. 119 and plates xxi. (London: H.M. Stationery Office.) 10s. net.

rapidly to a maximum (the gust), then falls off slowly to a minimum (the lull), and superposed on this general change there are many smaller irregular oscillations". Moreover, "the main gust and lull do not affect the direction greatly; in fact, the changes in direction produced by the rapid irregularities are as large if not larger than the changes produced by the main gust and lull". Of these two types of disturbance, the first-mentioned varies in magnitude according to the gradient of temperature in the vertical direction, and tends to vanish under conditions of extreme stability. This large scale type of disturbance Durst associates with convectional eddying in cells of a depth of perhaps 1500 feet, of length in the direction of the wind of the order of 3000-8000 feet, and of a width of perhaps 600-2000 feet. The small scale disturbances he considers to be of frictional origin, eddies set up by contact of the air stream with the surface of the earth; the diameters of these frictional eddies are of the order of 50-100 feet, and the axes may be oriented in all directions.

In Part V., A. F. Crossley takes up the discussion of the effect of the present theory of eddies on the variation of wind with height, and finds that simple equations of motion can be applied to the atmosphere only above a height of 1500 feet if super-adiabatic conditions are present in the surface layer, and above about 50 feet when there is an inversion.

A. H. R. G.

Sadi Carnot, 1796–1832

On Aug. 24, 1832, a hundred years ago, Sadi Carnot, the author of the famous memoir "Réflexions sur la puissance motrice du feu et sur les machines propres à développer cette puissance", died in Paris at the early age of thirty-six years. For some weeks previously he had been very ill with fever, and was only just beginning to recover when he fell a victim to the cholera epidemic which claimed some 18,000 persons in Paris alone.

Little notice was taken of Carnot's death, and no one realised that he had made a contribution to science which was destined to render his name immortal. His essay had been printed in 1824 by the minor Parisian publisher Bachelier, and had it not been for the comments on the views of Carnot by his countryman, Clapeyron (1799–1864), the engineer, who in 1834 wrote a paper entitled "Sur la théorie méchanique de la chaleur" for the journal of the École Polytechnique, it might well have been lost sight of altogether. It was Clapeyron's essay which attracted the attention of Kelvin when studying in Regnault's laboratory in 1845, and it was Kelvin who first mastered the principle enunciated by Carnot; as he was also the first to realise the merits of the work of Joule.

Carnot's essay was reprinted in 1871 in the *Annales scientifiques de l'École Normale supérieure*, and in 1878 it was again reprinted by the publishers Messrs. Gauthiers-Villars, together with a letter from Carnot's brother Hippolyte (1801–88) to the Paris Academy of Sciences, dated Nov. 30, 1878, a biographical sketch and extracts from Carnot's manuscripts. The centenary of the publication of the essay was celebrated at the P.N. Russell School of Engineering, University of Sydney, on Oct. 23, 1924; and again on Jan. 20, 1926, at a special meeting of the Société des Ingénieurs Civils de France, which was attended by the President of the Republic and many officials, savants, and engineers.

Except for two incidents, the life of Carnot [illegible] uneventful. He was born in Luxemburg on [illegible] 1796; but before he had reached manhood, [illegible] been overthrown, and a career which might otherwise have been spent on the battlefield was passed in the barracks and the study. He was taught mathematics by his father, and attended the Lycée Charlemagne; in 1812 gained admission to the École Polytechnique, and in October 1814 passed into the Corps of Engineers at Metz. Earlier that year he had, with his fellow students, served in a battalion formed for the defence of Paris, but he saw nothing of active service. For five years he was employed on routine work in various towns; in 1819 he entered the staff corps in Paris, in 1827 was made a captain of engineers, and the following year retired from the army.

A born student, Carnot when in Paris followed courses at the Collège de France, the Sorbonne, and the Conservatoire des Arts et Métiers, his scientific studies being interwoven with others on music, the arts, literature, and political economy. He made himself familiar with mechanical engineering and various industries, and it was the absence of any exact theory of the steam-engines of Newcomen, Watt, Smeaton, and Trevithick which led him to the study of heat and to writing his "Réflexions". Towards the end of his life he joined the Association polytechnique started by old students of the École Polytechnique for popularising knowledge, and had he lived longer he would no doubt have taken a prominent part in its proceedings.

Carnot came of a celebrated family of Burgundy, his father being Lazare Nicolas Marguerite Carnot (1753–1823), the mathematician and engineer who earned for himself the title of "the organiser of victory". Nicolas Leonard Sadi Carnot was his second son; an older one who had also been given the name of Sadi, after a thirteenth century Persian poet, died in infancy. Hippolyte was the third son, while his son was Marie François Sadi Carnot, who became President of the French Republic and was assassinated at Lyons on June 24, 1894.

Of the character of Sadi Carnot, his brother gives a pleasing sketch. Energetic, courageous, with few prejudices and many amiable qualities, Carnot left behind him manuscripts which not only contain

his ideas on heat, gases, vapours, and such matters, but also his thoughts on conduct and life. Thus he writes, on various occasions:

"Régler le matin l'emploi de sa journée et réfléchir le soir à ce qu'on a fait."

"La promptitude des résolutions s'accorde le plus souvent avec leur justesse."

"Parler peu de ce qu'on sait et point du tout de ce qu'on ne sait pas."

"La vie est un passage assez court. Je suis à la moitié du chemin. J'achèverai le reste comme je pourrai."

"Les lois de la guerre, dit-on; comme si la guerre n'était pas la destruction de toutes les lois."

Carnot had had an uncle, a magistrate who, stricken with apoplexy in court, had exclaimed, "Vous allez voir comment on passe courageusement de la vie à la mort". It was in that spirit that Carnot had faced the long illness which led to his own death.

Obituary

MR. GEORGE BARROW

MR. GEORGE BARROW, who died at his home in London on July 23, at the age of seventy-eight years, was a well-known geologist, who served for thirty-nine years on the Geological Survey of Great Britain. His earliest work was carried on in the north of England, especially in north Yorkshire. Afterwards he was transferred to Scotland, where he spent many years in surveying the southern Highlands, especially Aberdeenshire, Kincardineshire, and Forfarshire. This work brought him into prominence and placed him in the first rank of British authorities on metamorphic rocks and the tectonics of ancient crystalline provinces.

In 1900, Barrow returned to England and was entrusted with the mapping of parts of Cornwall and Devon, including Bodmin Moor and the southern flanks of Dartmoor. On his promotion to District Geologist in 1909, Barrow took charge of work in the London district, and interested himself greatly in economic geological problems, such as water supply and underground railways. He retired from the Geological Survey in 1915, and thereafter devoted his energies, to a considerable extent, to the local administration of the district in which he lived.

In his official work, Barrow was responsible for contributions to a large number of maps and memoirs published by the Geological Survey. Of these we may mention Cheadle (1903), Whitby (1882), Braemar (1912), Blair Atholl (1905), Scilly Isles (1906), Tavistock (1911), Bodmin (1909), Dartmoor (1912). This list might be considerably extended, but is sufficient to indicate the variety of his work. He was an active member of the Geological Society, the Mineralogical Society, and the Geologists' Association, served on their councils, and published papers in their transactions. In 1912 he received the Bolitho Gold Medal from the Royal Geological Society of Cornwall, and in 1913 the Murchison Medal from the Geological Society of London.

Barrow was a remarkably original field geologist, with a very acute eye for surface features and their relations to geological structure and history. His work on the high-level platforms of the west of England and the Pliocene features of the country around London is a good example of this. He was exceedingly painstaking and thorough, and was one of the first in Britain to perceive the importance of microscopic investigation of the older crystalline rocks. Working under the influence and tuition of Allan Dick, he applied these methods to Scottish Highland problems and obtained results of great value. In this he was really a pioneer. He was endowed with constructive imagination and a wonderful intuition, which led him often to arrive at conclusions very rapidly and in a manner which even his colleagues had some difficulty in understanding. Yet often these hypotheses, which seemed at first mere guesses, turned out to be sound. Consequently he had a very stimulating personality, and his conversation on geological topics was very inspiring, especially to younger men who had not his wide experience in the field. A genial companion and a generous opponent, he knew how to enjoy life, and retained his wide outlook, his courage, and his enthusiasm to the end of his days.

J. S. F.

MR. R. STAPLES-BROWNE, M.B.E.

RICHARD STAPLES-BROWNE, of Butler's Court, Alvescot, Oxfordshire, who died on June 5, was born in 1881, and from Rugby School went up to Emmanuel College, Cambridge, taking his degree by the Natural Sciences Tripos of 1902. He then commenced the medical courses, but the endocrine trouble which afflicted him throughout life called for a voyage round the world before he passed his second M.B. examination in 1906. About this time he came under the influence of William Bateson and relinquished medical study for biology, always his chief interest.

Staples-Browne's experimental work on inheritance in pigeons is among the best pioneer studies engendered by the rediscovery of Mendel's papers; he showed that Darwin's inquiry into the origin of the domesticated races of pigeons was unnecessarily complicated, and that his results are capable of simple explanation on Mendelian lines. Sex-linked heredity in doves was demonstrated by Staples-Browne just after this important condition had been discovered in poultry, and he may be said to have laid the foundation of our genetical knowledge of pigeons. During the War he joined up with the Medical Corps of the New Zealand Expeditionary Force, and, with the rank of captain, he did four years' service in its clerical and statis[illegible] branches in England, for which he wa[illegible] the M.B.E.

Descended from a long Oxfordshire ancestry, Staples-Browne inherited a country gentleman's love for ornithology, fishing, and shooting, but biological research was always foremost, and up to his last illness he was planning improvements in the laboratory which he added to the Tudor house he had modernised during the happy married life of his later years. He will be remembered as a most loyal friend, for his charming and courtly manner, for his wide interest in life, and for an early developed power of shrewd criticism in biological subjects. Hampered by long periods of bodily discomfort and occasional disabling illness, the amount and intrinsic value of his contributions to inheritance are a remarkable record of enthusiasm and moral courage defeating odds which would cause most men to relinquish original work.

WE regret to announce the following deaths:

Prof. J. C. Fields, F.R.S., research professor of mathematics in the University of Toronto, president in 1924 of the International Mathematical Congress, on Aug. 9, aged sixty-nine years.

Dr. T. H. Gronwall, known for his mathematical works, especially on theories of elasticity and differential and integral equations, on May 9, aged fifty-five years.

Dr. George F. Kunz, known for his work in mineralogy in the U.S. Geological Survey, and especially for his work on precious stones, on June 29, aged seventy-five years.

Capt. Poulett Weatherley, one of the earliest explorers of Northern Rhodesia, the Belgian Congo and Tanganyika Territory, and the discoverer of the source of the Congo, aged seventy-two years.

News and Views

Archæological Research and Government Control

A RESOLUTION of the first International Congress of Prehistoric and Protohistoric Sciences recently held in London expressed deep regret at the attitude of the Egyptian Department of Antiquities in putting obstacles in the way of the scientific study of Egyptian prehistory; and while expressing respect for the rights of the Egyptian nation to preserve and arrange its documents, requested the Egyptian Government to ensure facilities for study and precautions against action detrimental to research. The opinion of British archæologists, that the attitude of the Department towards archæological exploration by extra-territorial investigators is not in the best interests of science, has frequently been brought to the notice of the Egyptian Government. A resolution which expresses the opinion of a body so widely representative as an international congress may perhaps carry conviction that dissatisfaction with the methods of the Department is not merely the view of sectional interest.

THE situation is admittedly a difficult one. Nor does Egypt stand alone. Similar difficulties are bound to arise whenever a country which calls for exploration in the interests of archæological science is neither financially competent nor intellectually equipped to undertake such exploration on its own behalf. Preservation of finds intact and accessibility of the material for the purpose of study are also important factors in the situation. Archæological investigation unquestionably is being checked in several directions in present conditions. Financial assistance, which in any event is difficult enough to obtain at the present day, is being still further restricted by the uncompromising attitude of those in authority, who are in a position to dictate conditions. The institution of a body such as the Congress of Prehistoric and Protohistoric Sciences, which is above sectional interests, would seem to afford opportunity for the formulation of a settled policy which would reconcile, on an equitable basis, [illegible]ims of scientific study and research and the [illegible]tional authority, even with the admitted [illegible] other things being equal, national antiquities are best preserved, exhibited, and studied in their own regional environment.

Future Research Work in Prehistory

BEFORE rising, further resolutions were adopted by the Congress of Prehistoric and Protohistoric Sciences. The invitation to hold the next meeting at Oslo was accepted; and the president-elect, Prof. A. W. Brögger, of Oslo, who has acted as joint general secretary of the first meeting, was inducted into the chair by Sir Charles Peers, the retiring president. It was then resolved that research committees should be appointed to investigate specific problems and carry out certain specified pieces of work. One committee will investigate the relations which subsisted between the Ægean world and the Balkans and Danubian countries. Another is to study problems related to the civilisation of the western Mediterranean. Prof. Gordon Childe has been entrusted with the compilation of an international vocabulary of technical terms in archæology, with the co-operation of all countries represented at the Congress; while it is an instruction to the organising committee of the next Congress to investigate the possibility of a report on the systems of classification adopted by different schools of archæology.

Dental Mutilation in Early Times

ON page 284 of this issue we publish a summary of Sir Arthur Keith's report to the first International Congress of Prehistoric and Protohistoric Sciences on the human skeletal remains discovered by Miss Garrod in Palestinian caves in association with a mesolithic culture. The report directs attention to certain cultural practices for which the skeletal material affords evidence, such as the evulsion of the upper incisors and the practice of cannibalism. In the discussion which followed the presentation of the report, Prof. Elliot Smith expressed doubt as to chronology, and questioned the high antiquity of the practices to which Sir Arthur had referred the conditions observed in the skeletal material. In a letter on the Oldoway skeleton, which appears in the August issue of *Man*,

Prof. Elliot Smith, writing before the positive evidence pointing to the recent origin of that specimen was available, argues that the cultural evidence, upon which reliance had been placed in support of the antiquity of the remains, in effect tells against it. In particular, he maintains that the deformation of the teeth exhibited by Oldoway man, a filing away of the anterior surface of the lower incisors, first appears, with other forms of dental deformation, in human remains from a Ptolemaic-Roman cemetery near Dacca, in Lower Nubia, recorded by Dr. D. E. Derry and himself. He suggests, further, that the process of filing was the original device for removing the teeth, and was almost immediately superseded by lateral filing, or the more drastic evulsion. Therefore, he thinks, the practice of dental mutilation was not introduced before about 300 B.C. In this connexion we may direct attention to the recently published account of the fossil man of Asselar (Sahara) by MM. Boule and Vallois (see p. 280), in which the authors interpret the condition of the upper jaw as due to the evulsion of the upper incisors in early life, and refer to a similar condition in the fossil human remains of Afalou-bou-Rhummel (Algeria). The apparent age of the Asselar man at the time of the operation conforms to its generally accepted relation to puberty ceremonial; while the geological and palæontological evidence, if correctly recorded and interpreted, points unquestionably to a Pleistocene dating.

Radio Communication with very Short Waves

IT is announced in the *Times* of Aug. 15 that the experiments which are being carried out by Senator Marconi on communication by means of radio waves of very short wave-length have been successful. As communication was established between two places 170 miles apart, and as the wave-length he used was only 57 cm., the result is of great importance. Hitherto it has been considered impracticable to use such short wave-lengths for transmission owing to the curvature of the earth. The experiments prove that the range of communication with very short waves must extend much farther than the visible horizon. Many experiments, including some by Marconi himself, using very short waves, have been made previously in attempts to reach stations beyond the visible horizon, but all proved unsuccessful. The apparatus now used is of low power and is fitted with portable reflectors. In the recent tests, clear communication was established from Rocca di Papa, near Rome, to Cape Figari, in Sardinia. The transmitting apparatus is quite light, and can now be easily transported anywhere. Formerly the apparatus used was very heavy and cumbersome. It will be of great scientific interest to learn the greatest distance over which this new method can be used.

West Indian Hurricane Season

IN connexion with recent reports that a hurricane has swept along the Gulf coast of the United States, it may be noted that August is the first of the three months into which a very large proportion of West Indian hurricanes is concentrated, and that at least one of these tropical cyclones occurs in that month rather more often than not. Most of the storms that arrive early in the hurricane season sufficiently far west to cause serious damage in Texas, as has happened in the present instance, enter the mainland moving north-westwards and then northwards along a characteristically curved path, and begin to diminish in intensity on leaving the sea, but a great many of the August storms first appear farther east and pass across or to the east of the Florida peninsula. It is not yet possible to gauge the exact path followed by the recent storm, but Galveston and Freeport and, to a less extent, Houston were all affected by it. The deaths caused by it have apparently not been very numerous, considering the large amount of material damage, a fact which is attributed to the timely evacuation of the coastal lowlands. This suggests that the section of the forecast service of the United States Weather Bureau which issues hurricane warnings for the Gulf region deserves great credit for effective warnings issued in good time to be of practical service.

Laboratory for Freshwater Biological Research on Windermere

THE laboratories of the Fresh Water Biological Association's Station at Wray Castle, Windermere, were opened to public inspection on Aug. 10. A succession of microscopes was used to show the consecutive life stages from the plankton or microscopic plants through equally microscopic insects to the smallest fish. Exhibits, in tanks, of the small fish which feed on these and of the larger fish completed the life series. In addition, there were tanks containing leeches, fly larvæ, fish-like stage of the newt, and so on. The uses of nets and grabs for obtaining samples of life, water, and bottom material were also demonstrated. Diagrams showed the relations between wind direction, shoals, and the quantity of life, and the consequent variation in the number of fish an angler might catch. An ingenious and newly evolved apparatus involving a light-sensitive potassium cell and a two-valve amplifier, used in the evaluation of the light intensity at various depths, was shown. Research in progress was represented by an ingenious apparatus enabling the researcher to discover the variation in velocity with which a tape worm moves against, or with a constant current. The same water was circulated continuously, but owing to the necessity of keeping it untainted by metals it was pumped round by a water-suction pump. In addition there were numerous cultures of fly larvæ, which are being bred in order to discover which flies develop from named larvæ—flies and larvæ having been originally named irrespective of their relationship. The Fresh Water Biological Association is to be congratulated on the excellent arrangement of the laboratory, and on the great enthusiasm of the staff, and—a most encouraging sign—of the youthful and very keen body of research workers gathered together there.

Dungeness Preservation Fund

THE promontory of Dungeness is unique south-east coast of England as being area of any size remaining in a nat

state. It is of particular interest for its bird life, notably as the sole British breeding ground of the Kentish plover. Other uncommon birds also nest there, such as the stone curlew, and there is a large colony of terns. All this may soon be irretrievably lost if a threat of bungalow building along the sea-front cannot be averted. To secure the position, therefore, efforts are being made to raise £9000 for the purchase of 271 acres as a bird sanctuary and Nature reserve, to be administered either by the National Trust or by the Royal Society for the Protection of Birds. This area, with its half-mile of shore frontage, is the part immediately in danger, and its price is, unfortunately, already that of a building site. Its acquisition, however, would increase the sanctuary value of adjacent land that is already preserved, and would make inaccessible to development a further stretch of coast lying beyond. The area is thus a key position, and the success of the scheme for its security is very greatly to be desired. The treasurer of the fund is Mr. Percival Jackling, Lloyds Bank, Folkestone.

The Grid and the Cost of Electricity

In connexion with Sir Archibald Page's speech, a résumé of which was given in Nature of Aug. 6, p. 212, Col. H. L. Crosthwait, late R.E., writes asking whether the advent of the 'grid' is likely to reduce the price of electricity or not. So far as can be seen at present, it will reduce the price to numerous consumers. The large stations recently built are generating electricity with far greater economy than the older stations which they replace. The use of the grid will be a great help in securing continuity of supply, and will make it unnecessary to keep a large number of costly machines in reserve in case of breakdowns. The standardisation of the pressures and frequency of supply has cheapened the cost of machines, apparatus, and lamps. We have not heard complaints from any consumer that the electricity companies have been raising the price of electricity; on the contrary, many of them have recently made substantial reductions. It is probable that some consumers will be little affected by the advent of the grid, but many will get their electricity cheaper, and very many dwellers in towns and villages will be able to get electric light and power which they otherwise would not have obtained. The grid is the logical engineering outcome of Ferranti's scheme for lighting London, using electricity at high pressures, first put into operation about forty-four years ago. Its critics have suggested nothing better; as a rule, they desire progress to be made by costly competitive methods. In the future the grid will probably be considerably modified, but at present consumers can look forward to a gradual lowering of the price of electric light and power.

Monument to Otto Lilienthal

On Aug. 10 a monument to Otto Lilienthal, the ...man pioneer of gliding flight, was inaugurated at ...hterfelde, Berlin, on the mound from which ...de many of his flights forty years ago. ... was piled up for the purpose by Lilienthal, is some forty-nine feet high, and a photograph taken some years ago shows its sides covered by shrubs and the top surmounted by a small temple-like construction consisting of pillars supporting a slightly sloping round roof. According to the *Times* for Aug. 10, the mound has now been cleared of the trees and shrubs, while in the monument at the top, and beneath the central opening in the roof, is a silver globe inscribed with particulars of famous flights. The globe is mounted on a basalt block. A photograph of the inauguration of the memorial appeared in the *Times* for Aug. 11. Lilienthal was a successful engineer and manufacturer. He was born on May 23, 1848, at Anklam and died on Aug. 10, 1896, at Rhinow through an accident while gliding. Another monument to Lilienthal was inaugurated at Lichterfelde in 1914. This consists of a stone pyramid, bearing on one side a bust and on the summit a figure of a man with outstretched arms supporting a pair of wings.

The Workers' Educational Association and Science

At the Annual Conference of the Workers' Educational Association last year, it was resolved "to investigate the possibilities of stimulating further interest in the study of science [that is, natural science] on a non-vocational basis", and the result of the investigation by the Executive Committee has now been circulated. To a scientific worker, it seems in some respects a strange document to be produced in 1932. It says, "The Adult Education Movement cannot afford to neglect scientific thought and knowledge. Ignorance of the influence of science should belong to the past"; and then, "The study of science, in some of its branches, provided the approach is of the right character, is as attractive and has as great a bearing on social conditions as some of the social sciences". As if the very foundations of social conditions did not rest upon heredity, and health, and the fight against disease, and the production of food, whether from the fisheries or agriculture, and the growing of the raw materials of commerce, and the constant battle against pests, whether they be parasites or plagues, and upon life itself! The Report says, further, "It is only in relation to the question as to how far and in what ways natural science influences and affects society, that our classes can maintain their interest in subjects of this character". It is on strong ground, however, in holding that the teaching of natural science, in so far as it is to be promoted, should avoid the formal lines of a university degree course, and should be of such a character as to attract the uninitiated.

The Committee, basing upon its district reports, finds that "there is a lack of interest so far as the adult population is concerned in the study of science". We think this may be due partly to the ignorance of people as to what natural science means, and partly to the failure to offer suitable courses. But we congratulate the Committee on its unanimous opinion "that the Association should seek to stimulate further interest amongst adult students in the study of science on a non-vocational basis". Towards this end it makes several recommendations, of which the most

promising seem to be the organising of district panels of suitable lecturers, the inclusion of provisional science courses in the programmes of classes, and propaganda to encourage interest in the study of science, by printed leaflets and by peripatetic lecturers capable of interesting popular audiences. Two interesting "general recommendations" are added: that there should be "a rapid and progressive improvement in the supply of films and slides applicable to science teaching", and that for this purpose "the Association should investigate the possibilities of the setting up of a national organisation for the production and distribution of educational films".

The Science Museum during 1931

THE Report of the Advisory Council of the Science Museum of 1931 is the first issued since the Council was reorganised on lines suggested by the Royal Commission on National Museums and Galleries. With Sir Richard Glazebrook as chairman, the Council now includes three representatives appointed by the Board of Education, and twenty-six representatives of various scientific, technical, and industrial institutions. The Royal Commission also recommended that the Advisory Council should be assigned a more active part in the management and development of the Museum, and the adoption of this recommendation has already resulted in the appointment of a Standing Committee which will meet four or five times annually, and of three small sub-committees which are to report on the Science Library, the development of the Electrical Engineering Section, and on an exhibition of pottery and porcelain manufacture. The Report contains details of the attendances, lectures, temporary exhibitions, acquisitions, and of the Library. It also contains a tribute to the late Sir Hugh Bell, who was chairman of the Advisory Council from 1912 until 1931, and to the Director, Sir Henry Lyons, and his staff. Among the acquisitions during the year are the apparatus used by Sir William Ramsay in his work on the rare gases of the atmosphere, the fine collection of optical instruments, numbering nearly 600, given by Mr. T. H. Court, and the cinematographic apparatus invented in 1887–89 by Louis Augustin Le Prince, who disappeared while travelling in France in 1890.

Safety in Mines

THE Safety in Mines Research Board has just issued Paper No. 74, which contains an account of an important conference on safety in mines held at Buxton last year. There seems no adequate reason why information about this important conference should have been so long delayed, though there may have been difficulty in getting the authors of the various papers to correct their contributions. The meeting derives its great importance from the fact that it was the first international conference of this kind. In addition to the British representatives, there were delegates from Belgium, France, Germany, and the United States. A number of important papers on mining explosives were read, and proposals were made for future international meetings, subject to ratification by the organisations concerned—a ratification which, we presume, will certainly be forthcoming. Perhaps the most important of the suggested future arrangements was that "Periodical meetings of the directors of research shall be arranged at each research station in rotation". This arrangement would thoroughly ensure the international character of future conferences, and it is a most welcome sign that the question of safety in collieries is for the future to be treated as an international question and not as one possessing local interest only.

Geodetic Surveying in the United States

THE annual report of the Director of the United States Coast and Geodetic Survey for the year 1930–31 (Washington, 1931, 45 pp., 60 cents) describes briefly the wide range and large extent of the activities of this important and progressive organisation. It has as a frontispiece a photograph of the new surveying vessel (one of several possessed by the Survey) *Hydrographer*, commissioned in March 1931, and fully equipped with sound-ranging apparatus for depth-surveys; sound-ranging is also used for locating the position of the ship from the shore at the time of each depth-measurement. The use of these methods has greatly increased the rapidity of the coastal survey work. The control survey work on land has also been rendered much more rapid and less expensive by abandoning the erection of the large wooden towers formerly used in flat or rolling country, at points about ten miles apart, to enable the observers to see across such distances over intervening trees and other obstructions. These towers were often 100 feet or more in height, each being double, so that the observer could walk on the outer platform, unconnected with the inner tower carrying the instrument. They contained large quantities of material, used once only, and required much time to erect. They are now replaced by portable steel towers, which can be erected by five men in less than a single working day, and used many times, their transport from one place to another being made by trailer trucks. An improved and smaller theodolite has also been devised and brought into use.

Czechoslovakian Contributions to Science

THE scientific communications to the Czech Academy of Sciences during 1928 and 1929 have now been published in French or English in volumes 29 and 30 of the *Bulletin International* of the Academy. Among the papers presented are several by Dr. F. Němejc dealing with his palæobotanical investigations on some quaternary deposits in the district around Ružomberok in Slovakia. Dr. R. Kettner has made a similar study of the geological formations in the Hron Valley, and Prof. Ulrich describes the minerals variscite and barrandite from Třenice and also a Slovakian rutile. Dr. J. Hahn's account of the life history of *Monocystis Mrazeki* is illustrated with some fine photomicrographic plates, whilst M. Uher's communication dealing with the genesis of nerve elements cultivated *in vitro* is similarly illustrated. D[illegible] Jirovec has succeeded in observing and re[illegible] a coloured plate some twenty stag[illegible]

division of *Trypanosoma evansi*. His observations apparently contradict the earlier ones of Roskin. In pure chemistry, Prof. Tomiček and Dr. Janský have made an exhaustive study of the methods available for determining mixed halides in connexion with the analyses of bromides and iodides in spa and thermal waters. The improvements which they have introduced enabled them to give more accurate and detailed results. It was long supposed that the waters from Darkov, Silesia, were the richest in iodine, but according to these authors the waters from Čiz in Slovakia and Bad Hall in Austria are still richer, with a total iodine content of more than 28 mgm. per litre.

Colloid Aspects of Textile Materials

A GENERAL discussion on "The Colloid Aspects of Textile Materials" has been arranged by the Faraday Society to be held in the Department of Chemistry of the University of Manchester on Sept. 21–23, under the presidency of Sir Robert Mond. An introductory address will be given by Prof. F. G. Donnan. The general subjects to be discussed include cellulose and its derivatives, lignin and keratin; fibre particles, their production, deformation, and degradation; and manufacturing processes. Among the foreign guests who will speak at the discussion are: Prof. H. Mark (Ludwigshafen), Prof. H. Staudinger (Freiburg), Dr. S. E. Sheppard (Rochester, U.S.A.), Dr. J. J. Trillat (Paris), Prof. K. Freudenberg (Heidelberg), Prof. O. Roehrich (Paris), Prof. Herzog (Berlin), Prof. J. R. Katz (Amsterdam), Mr. C. R. Nodder (Lambeg), Prof. E. Elöd (Karlsruhe), and Prof. P. Krais (Dresden). Further particulars of the meeting can be obtained from The Secretary, Faraday Society, 13 South Square, Gray's Inn, London, W.C.1.

Swedish Meteorology

THE State Meteorological and Hydrographical Service of Sweden has published as Part 2 of the Årsbok for 1932 the meteorological statistics of the country for the year 1929. The data are collected from more than two hundred stations, for each of which pressure, temperature, humidity, wind direction and force, cloud, and rainfall are given in three records on every day of the year. For some forty stations, monthly and yearly means are also given for each hour of observation. There is no discussion of the data, but the usefulness of this publication is enhanced by the headings and notes being given in French as well as Swedish.

Announcements

PROF. F. WOOD JONES, professor of anatomy in the University of Melbourne, will go to Peking as head of the Department of Anatomy at the Peking Union Medical College, during the absence of Prof. Davidson Black on leave in Europe and America during the next six months.

THE valuable collection of Australian Coleoptera, containing a great store of 'types', of the late Mr. Lea, who died at Adelaide on Feb. 29 (see May 28, p. 786), has recently been purchased by the Governors of the South Australian Museum, partly as a memorial of his work.

THE "Achema VII" (the German Chemical Plant Exhibition, Ausstellung für chemisches Apparatewesen), arranged by the "Dechema" (Deutsche Gesellschaft für chemisches Apparatewesen, of Seelze, Hannover), will be held at Cologne in 1933 (probably on June 2–11, 1933) at the same time as the conferences of the Verein Deutscher Chemiker, the Deutsche Kautschukgesellschaft, the Deutsche Brennkrafttechnische Gesellschaft, and the Dechema. Other scientific and technical societies will also hold their annual meeting at Cologne during the same period.

THE following awards for the year 1932–33 have been made by the Salters' Institute of Industrial Chemistry: Fellowships renewed to: D. J. Branscombe, University College, Exeter; H. G. Simpson, East London College; J. L. Sweeten, St. Catherine's College, Cambridge; P. Chisholm Young, Trinity College, Cambridge. Fellowships awarded to: S. C. Britton, Pembroke College, Cambridge; E. H. T. Hoblyn, Imperial College of Science and Technology; R. H. McDowell, Jesus College, Oxford; G. Pearce, University of Birmingham. The Salters' Institute has also awarded 107 grants-in-aid to young men and women employed in chemical works, to facilitate their further studies.

POPULAR science book lists, 27 in number, have been prepared by a special committee of the American Association for the Advancement of Science, aided by some 300 specialists in colleges, libraries, and museums. The object of the series is to offer to the general reader reliable guidance in the choice of a few elementary science books, and in following up such reading by systematic study. The lists are annotated, and cover the whole field of elementary physics and chemistry, natural history and physiography, the history of science, and the teaching of science.

THE Arctic Institute of Leningrad has prepared a new map of the polar areas of the Soviet arctic regions. The map shows the regions discovered by recent Soviet expeditions, and has been compiled in both Russian and English.

MESSRS. Watts and Co. announce the early publication of "The Universe of Science", by Prof. H. Levy, in which recent pronouncements of Sir James Jeans, Sir Arthur Eddington, and General Smuts regarding the universe are critically examined.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A lecturer in metallurgy and applied chemistry at the Royal Naval College, Greenwich—The Adviser on Education, Admiralty, Whitehall, S.W.1. (Aug. 22). An assistant lecturer in engineering at the School of Mines, Treforest—The Director of Education, County Hall, Cardiff (Aug. 26). A de Beers professor of mining and surveying at the University of the Witwatersrand, Johannesburg—The Secretary, Office of the High Commissioner, South Africa House, 73 Strand, W.C.2 (Sept. 7).

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Theory of Induced Polarities in Benzene

THE letter from Dr. E. and Prof. W. Hückel in these columns [1] explains that "H^+" on page 326 of Dr. E. Hückel's original paper was a misprint for "H-atom". The misprint, occurring at a crucial point, was unfortunate, and in the light of this explanation we naturally withdraw all such criticism as was based on the misapprehension that Hückel postulated extrusion of proton during the ordinary "substitution of hydrogen" in the aromatic series.

Our objections to Hückel's theory as we now understand it are no less serious than when our first letter [2] was written. E. and H. Hückel now say that "the assumption in Hückel's theory is . . . only that for a definite reaction the heat of activation is smaller for a hydrogen atom bound more loosely and greater for a hydrogen atom bound more strongly. It cannot be denied that for all simple substitution reactions which have been investigated *quantitatively* up to the present time, this assumption—taking the charge density calculated by Hückel—leads to results which are in agreement with observation."

We may point out that the apparent agreement is real *only if Hückel's additional assumption relating to the direct connexion between the strength of the* bond in C-H and the Coulombic attractive force on the nucleus of the H-atom can be justified. Even if it could be justified, it has not been shown that the few data quoted by Hückel are inconsistent with the theory of aromatic substitution which we support. In contrast to this state of things, there is a vast body of data which fit in most satisfactorily with our own ideas but not with Hückel's, and no better illustration of this statement is needed than the statement made by Dr. E. and Prof. W. Hückel that "We cannot see what connexion there is between the dissociation of acids and bases and substitution reactions in benzene".

That there is, nevertheless, a very close connexion between these phenomena has, we believe, been widely recognised, in English-speaking countries perhaps more particularly, since the publication of the classical paper [3] of Flürscheim on the subject, and although organic chemical theory has undergone revolutionary changes during the interval and many of the examples, such as aliphatic acids, quoted by Flürscheim are now considered inappropriate, the paper embodied a discovery of first-rate importance, which is only emphasised by addition of new examples that are even more convincing than those given by the discoverer.

We would direct attention first to the mono-substituted phenols. Adequate data for use in the above connexion are available only in three cases: (*a*) the cresols (methylphenols), (*b*) the dihydroxybenzenes (hydroxyphenols), and (*c*) the nitrophenols. Of the three cresols, the meta-derivative is the most acidic.[4] Of the hydroxyphenols, the meta-derivative has a higher ionisation constant than the ortho-derivative,[5] and partition measurements made in the laboratories of the University of Manchester prove that the meta-derivative is also a more powerful acid than the para-derivative. Of the three nitro-phenols, on the other hand, the meta-derivative is much the weakest acid.[6] These cases represent typical alternate effects as this expression is now most widely used, no reversals in sign being required or implied.

The significance of the data relating to the acidities of isomeric substituted phenols can best be appreciated by reference to a well-known generalisation illustrated by the following quotation from G. N. Lewis: [7] "If we consider corresponding hydroxides of nitrogen, phosphorus, arsenic, antimony, and bismuth, we see the effect of the diminishing pull of electrons by the central atom as we proceed from nitrogen to bismuth. The hydroxides become progressively weaker acids and stronger bases."

The application of this generalisation to the arrangement C – OH in isomeric phenols leads to the conclusion that, other things being equal, the acidity of the hydroxyl group will be most pronounced when the group is attached to that carbon atom in the neighbourhood of which the electrons are most under the control of the central system either of the carbon atom or of the aromatic ring as a whole—in other words, at the carbon atom where the negative charge density is least or the positive charge density is greatest. In the three trios of substituted phenols above mentioned, the data, combined with Lewis's generalisation, show that the distribution of the charge densities in E. Hückel's two pictures (*loc. cit.*, p. 301) must be incorrect.

Relationships between isomeric substituted benzoic acids are more complicated. Nevertheless, as was pointed out by Flürscheim, the ionisation constant of the meta-substituted acid is greater than that of the para-substituted acid when the substituent is of the '*o-p*-directive' type, while the converse is true when the substituent is of the 'meta-directive' type. This generalisation holds good for the chloro- and nitro-benzoic acids [8] cited by Dr. E. and Prof. W. Hückel in evidence against our views, and is quite independent of whether the acids are weaker or stronger than benzoic acid, a question which depends mainly on the magnitude and orientation of the dipole moment associated with the introduction of the substituent into the aromatic system.

Our idea that attachment of the substituting agent to aromatic carbon precedes elimination of proton and is not simultaneous with the latter process is admittedly not proved, but it has served as a useful working hypothesis which has helped to correlate known data and to foresee others. Our fundamental thesis is that substituting agents of the electron-seeking type, such as halogens, sulphuric acid and sulphuric anhydride, nitric (or nitrous) acid, enter *most readily* into reaction with those carbon atoms of the aromatic ring at which there is an electronic excess, whilst agents such as alkalis, amines, metallic cyanides and sulphites, which act normally through their anions or by using their own electrons to form new covalencies, enter into reaction *only* with aromatic carbon atoms at which there is a decided electronic deficiency.

Emulsification

IN 1925, Seifriz[1] made a number of interesting observations on the emulsification of hydrocarbon oils with water, using casein as emulsifier. He showed, for example, that oils ranging in density from 0·664 to 0·820 gave stable emulsions of the oil-in-water type; those of density 0·857 to 0·895 gave stable emulsions of the water-in-oil type; while oils intermediate in density gave emulsions which separated immediately. So far as we are aware, no adequate explanation of these results has been offered, but a simple explanation is possible on the basis of recent developments in the study of the liquid state.[2] The hypothesis to be advanced has important consequences for the theory of emulsification and detergent action.

Liquids are no longer to be regarded as structureless, and in the case of aliphatic compounds, the tendency to incipient crystallisation increases with the length of the carbon chain. The resistance to dispersion of liquids composed of long-chain molecules must therefore increase with the chain length, that is, in the case of the paraffins, with the density of the oil. Hence the inversion of emulsion type observed by Seifriz is due simply to the increased resistance to dispersion of paraffins of high molecular weight, caused by incipient crystallisation.

When oils and related compounds are spread as a thin film on a solid surface, the tendency to incipient crystallisation manifests itself in the form of adhesion to the surface. In this case, removal of oil by means of soap solution is conditioned by the magnitude of adhesion and interfacial tension, as shown by the following experiments.

A mineral oil was subjected to repeated fractional distillation to obtain nine fractions of increasing boiling point. Each fraction was then used to oil a wool fabric, which was afterwards scoured with soap and soda solution, using a standard mechanical technique. The amount of oil remaining in the fabric was found

Percentage by weight of Oleyl Alcohol in mixture.	Oil-water Interfacial Tension (dynes/cm.).	Residual Oil (per cent on weight of wool).
0·0	47·9	2·50

100·0	14·4	2·66

to increase with the boiling point of the fraction, according to a law which indicates that the difficulty of removing oil increases in proportion to the length of the molecule.

Although the preceding results serve to indicate the importance of the adhesion factor, the difficulty of removing mineral oil from a solid surface such as wool is due mainly to high interfacial tension. Oleyl alcohol on the other hand, possesses a low interfacial tension, but is even more difficult to remove than mineral oil. This result must be referred to adhesion of a very high order, due to the polar character of the molecule and its high molecular weight.[3] Mixtures of mineral oil and oleyl alcohol are as a rule more easily removed than either oil alone. This important result discriminate between the two factors of interfacial tension, and is illustrated by the data of the accompanying table, obtained by oiling a wool fabric with 5 per cent by weight of each mixture, the fabric being then scoured as before, and the residual oil estimated by ether extraction.

As might be expected from the preceding results, both mineral oil and oleyl alcohol were found to be difficult to emulsify with soap solution, but the mixture of mineral oil and 6 per cent oleyl alcohol, for example, gave an extremely stable emulsion under similar conditions.

In conclusion, it is evident that the formation of emulsions, especially in the case of oils and related compounds of high molecular weight, is not determined simply by the magnitude of the interfacial tension and the formation of a stable adsorbed film at the interface. The cybotactic condition of the liquid to be dispersed is of equal importance in ordinary emulsification; while, in scouring processes, related adhesion phenomena acquire exceptional significance.

Inhibition of Enzymes by Carcinogenic Compounds

EXPERIMENTS carried out in this laboratory[1] have shown that 1 : 2 : 5 : 6-dibenzanthracene and 5 : 6-*cyclo*-penteno-1 : 2-benzanthracene are the most carcinogenic of pure compounds yet described. The action of these compounds and of certain non-carcinogenic hydrocarbons on the oxidising enzymes of yeast and muscle has been studied. The carcinogenic and other hydrocarbons dissolved in benzene or toluene were shaken up with enzyme preparations, and the effect on the activity of the enzyme measured. In no case was indophenol oxidase of yeast or muscle affected by any such treatment.

The oxidation of lactate by lactic dehydrogenase of yeast or muscle was, however, inhibited by a dilute solution of the hydrocarbon in benzene or toluene which had been exposed to air and light. Exposure to air in the dark, or to light out of contact with air, was ineffective. Solutions activated by exposure to ultraviolet light became coloured yellow or brown and non-fluorescent. The amount of inhibition produced in this way on a yeast lactic dehydrogenase by several hydrocarbons treated in a comparable manner was as follows:

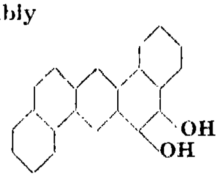
	Percentage Inhibition of Enzyme.	
Toluene control . . .	0	
(1) Anthracene	30	Non-carcinogenic.
(2) 1 : 2-Benzanthracene . .	28	,,
(3) Chrysene	26	,,
(4) 5 : 6-*cyclo*-Penteno-1 : 2-benzanthracene	55	Carcinogenic.
(5) 1 : 2 : 5 : 6-Dibenzanthracene	62	,,
(6) Polycyclic hydrocarbon from coal tar	74	More carcinogenic than (4) and (5).

In each case, 0·005 mgm. of the hydrocarbon was added to 1 c.c. of enzyme solution, which reduced 1 c.c. of 1/5000 methylene blue in the presence of lactate in 10 minutes at 40°. The maximum concentration of hydrocarbon is thus 1 part in 400,000.

The inhibitory action is greatest in the case of the carcinogenic compounds. The inhibition in the case of anthracene is not due to the presence of dianthracene, as this compound is quite inactive. **1 : 2 : 5 : 6-Dibenzanthracene was recovered unchanged after treatment which converts anthracene into dianthracene.**

The inhibitory factor was slightly soluble in water and more soluble in alkali, as was the colouring matter produced by exposure to light.

The chemical nature of the inhibiting factor is under investigation. It is possible that it is an *o*-hydroquinone; it does not appear to be an oxidation product in which *meso*-carbon atoms are involved. Comparison with reduced β-naphthaquinone and a reduced 1 : 2 : 5 : 6-dibenz-3 : 4-anthraquinone[2] showed the activity to be similar to that developed by the compounds named in the table above. The active compound derived from 1 : 2 : 5 : 6-dibenzanthracene is therefore possibly



Such a compound would have the structure $-\underset{|}{C}OH-\underset{|}{C}OH-$ which is similar to one of the groupings considered by Quastel and Wooldridge[3] to be necessary for the inhibition of lactic dehydrogenase. Full details of these experiments will be published shortly.

Isolation of Chemically Unstable Substances from Animal Tissues

IN the course of a study of some chemically unstable constituents of muscle tissue, we have made successful use of the following method for obtaining protein-free extracts of muscle. It has the merit of yielding, without departure from neutrality, a protein-free solution of the water-soluble constituents of muscle in a concentrated form. We have been unable to find a description of this technique in the literature, but should be grateful for information as to earlier examples of its use.

The method is based upon the facts that at 32° C. the solubility of sodium sulphate in water is at its maximum—50 gm. of the anhydrous salt to 100 gm. of water—and that if such a solution is cooled to 0° C., 96 per cent of the salt crystallises out as the decahydrate.

If muscle tissue, which contains water to the extent of 80 per cent of its weight, is minced with 40 per cent of its weight of anhydrous sodium sulphate, about three-quarters of the water of the muscle can be expressed without difficulty in the form of a saturated solution of sodium sulphate at 32° C. The solution contains no protein. The mother liquor poured away from this solution after chilling would be expected, on the basis of the figures given above, to contain the water-soluble constituents of the muscle in a concentration about three times greater than in the muscle. The following table, taken from a typical experiment, shows that this is the case.

The yield, unless special precautions are taken, is not very good—50-60 per cent—but in view of the ease and rapidity of the process and the high concentration of the extract, this is, for most purposes, not a serious drawback.

We have applied this technique so far only to the isolation of creatine, which can be precipitated immediately from the extract by addition of acetone, and of carnosine and anserine, which can be prepared from the extract by the use of copper carbonate,

	Concentration in Muscle. Mgm. per 100 gm.	Concentration in Na_2SO_4 Extract. Mgm. per 100 gm.	Concentration ratio.
Carnosine (by Pauli reaction)	35	112	3·2
Non-protein nitrogen	247	690	2·8
Lactate	250	700	2·8
Total phosphorus	118	303	2·6

acetone, and ammonia. The yield of crystalline copper carnosine or copper anserine compares favourably with the yields recorded by investigators using more elaborate methods. We have obtained in this way anserine from the muscles of sheep, goat, and rabbit, and carnosine from ox and frog muscle.

Observations on Filmed and Filtered Vowels

SOME specimens of film curves of German vowels obtained by the Vienna method of recording (wire in magnetic field slantways across a slit[1]) are reproduced in Fig. 1. Inspection of the curves reveals the following facts: (1) A vowel is made up of a series of adjacent vibration profiles; (2) the profiles differ progressively in length, amplitude, and form; (3) each

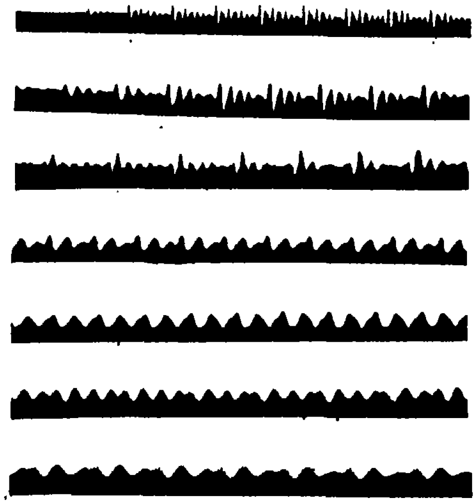

FIG. 1.—Film curves of vowels.

profile begins strong and becomes steadily weaker: (4) within each profile various characteristics, for example, maxima, are repeated; (5) different vowels show systematic differences of profile. Measurements reveal the following additional facts: (6) the frequencies of the inner repetitions change within each profile; (7) the rate of weakening changes within each profile.

These facts lead to the following conclusions: (1) The vibration profile is initiated by a sharp impulse that does not appear in the curve of the profile; (2) the profile consists of a more or less rapidly fading free vibration of complicated form.

The numerous systems of inner repetitions that the free vibration constituting the

be considered as the sum of a series of component free vibrations. Let us make this supposition and indicate the radian frequencies of the component vibrations by $\omega_1, \omega_2, \omega_3, \ldots$ Analyses of the profiles show that *all* the frequencies from 0 to ∞ are present to a greater or less degree. The profile is therefore not a sum of a few discrete free vibrations as ordinarily supposed, but an integration of an infinite number of such vibrations differing infinitely little from one another. The profile is therefore not a sum of discrete frequencies, but an integration over $d\omega$ between 0 and ∞. Each free vibration has a decremental index p. The analyses show that the decremental indices are infinitely variable, and that not one or a few but an infinite number of decremental factors are present between 0 and ∞. The decrement for each of the inner frequencies is therefore an integration over dp between the limits 0 and ∞. The amplitude of each inner vibration determines the amount of its contribution to the profile. The amount of the particular amplitude for a given frequency depends on the forces that control the formation of the profile. For a given profile it is determined by an integration over the particular frequency with the form of the profile $f(t')$ as amplitude within the limits α, β of the profile.

A complete expression for a vowel profile requires the formula:

$$y = f(t) = \frac{1}{\pi}\int_0^\infty d\omega \int_0^\infty dp \int_\alpha^\beta f(t')e^{-\omega p t'} \cos \omega(t' - t)dt'. \quad (1)$$

The change of the radian frequency and the factor of decrement as established by the measurements reported above require the additional equations:

$$\omega = f_\omega(t') \text{ and } p = f_p(t'). \quad . \quad . \quad . \quad (2)$$

The process that is expressed by formulæ (1) and (2) is a continuous affair that cannot be represented by any sum of discrete factors except as an approximation. A vowel profile is therefore unanalysable into a limited number of variables.

Equations (1) and (2) represent exactly what occurs in the vocal cavity. This does not consist of a set of cavities connected by orifices but of one cavity of complicated form that cannot be analysed into separate cavities. A sharp blow arouses a vibration that has every possible frequency between the limits of 0 and ∞. Just how strong each one of the infinitely numerous frequencies is depends on the shape of the cavity. The factor of decrement depends not so much on the inner work of the vibration as upon the softness and moisture of the walls of the vocal cavity. These may have any values. The shape of the vocal cavity is never constant for even the briefest instant; it is constantly and continuously changing according to the muscular movements that regulate it. These in turn are under the control of the various nervous and psychic centres that act in response not only to the speech impulse but also to the constant regulation by the entire nervous system and intellectual and emotional forces. This continual change results in the changes of inner frequency and decrement expressed by the equations in (2).

The essential characteristic of a vowel profile is its form. This view has recently received striking confirmation. At a recent demonstration by the British Post Office the attendant was good enough to carry out the following experiment. With a gramophone record of speech in connexion with a loud speaker various regions of frequency were filtered out as follows: (1) all frequencies above 1350; (2) all frequencies below 750; (3) all frequencies above 1350 and below 750; (4) all frequencies between 750 and 1350. The musical character of the speech changed with every change, but the specific characters of the vowels were unchanged. This leads to the rather startling conclusion that *the character of a sound as a vowel does not depend on the presence of any special frequencies.* The differences among the vowels therefore do not depend on the presence or absence of any particular tones or regions of tone. Any region of frequency assigned to any particular vowel can be filtered out with no change in the vowel except in regard to its musical character. Moreover, a small region of frequency anywhere is sufficient to give the vowel character. The conclusion cannot be avoided that the vowel character depends on the general shape of the vibration profile and that any frequencies of any kind may be present provided they give the same general form of profile. This would explain the otherwise unexplainable fact that a magpie with extremely small vocal organs of a kind different from human ones can imitate a man's voice so successfully.

The conclusion is inevitable that a vowel profile is a course of air vibration, muscular movement, nerve currents, and inner (psychic) activity. Any representation by a Fourier analysis, a physical analysis or synthesis, or otherwise into a limited number of variables can be only an approximation. A vowel profile, like a face profile, is recognised by its *form*; the one is a form in time, the other a form in space. Neither is recognised as a series of numbers. In both cases the form may be enlarged or diminished—the one in time (pitch), the other in space—without loss of recognition provided there is no distortion.

Diffraction of Gas Atoms

THE development of molecular ray technique makes possible investigations of the scattering of one beam of gas atoms by another. It is therefore of considerable interest to examine the conditions under which effects characteristic of the wave nature of the atoms would be observed. The angular distribution of the scattered atoms may exhibit maxima and minima, due either to the usual diffraction phenomenon or to the identity of the colliding particles if the atomic beams are composed of similar atoms.

We have therefore investigated theoretically the elastic collisions of two helium atoms with kinetic energy of relative motion (taken as kT) corresponding to temperatures of 20° C. and −185° C. respectively. For this purpose we have used an interaction energy given by Slater and Kirkwood,[1] and the theory of collisions due to Faxen and Holtsmark,[2] in which the scattered amplitude is given in relative co-ordinates by the series

$$f(\theta) = \frac{\lambda}{4\pi i}\sum_{n=0}^{\infty}(2n+1)(e^{2i\delta_n} - 1)P_n(\cos\theta),$$

the phases δ_n depending on the interaction energy and the energy of impact. λ is the associated wave-length.

For gas atoms a large number of terms of this series is required, and the evaluation of the phases by numerical integration of differential equations becomes very tedious. We have therefore used an approximate method of solution due to Jeffreys[3] for small values of n, and Born's approximation[4] for large values of n, intermediate values being given by interpolation. This method was tested by applying it to the calculation of the angular distribution of elastic scattering of 54 volt and 122 volt electrons in mercury vapour, good agreement being obtained with the experimental results of Arnot.[5] Since the completion of these calculations there has appeared a note by Henneberg,[6] who has obtained good agreement

with the experimental results for 135, 480, and 812 volt electrons by using a similar method.

In a co-ordinate system in which one atom is initially at rest, the number of atoms scattered between the angles Θ and $\Theta + d\Theta$ will be of the form $I(\Theta) \sin 2\Theta d\Theta$. The function $I(\Theta)$ obtained for the helium atom collisions is illustrated in Fig. 1, showing the existence of marked diffraction effects.

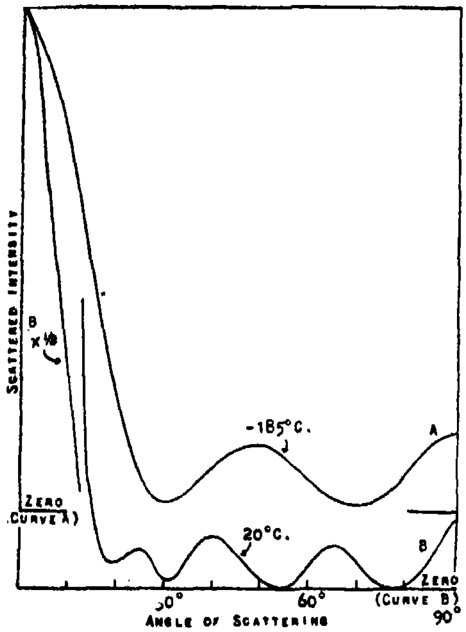

FIG. 1.—Angular distribution of function $I(\theta)$ for helium atoms scattered by helium atoms with relative velocities corresponding to temperatures of 20° C. and −185° C.

Allowance has been made for the identity of the helium atoms.[7] The collision diameter is very nearly the same for both relative velocities, being 2·4 A.

Unfortunately, direct experimental verification of these curves is difficult, owing to the necessity of obtaining monochromatic molecular beams. However, the effect should be apparent in the viscosity and other transport phenomena in helium. It is hoped to investigate this later.

The Velocity of Light

IN articles in NATURE and elsewhere, M. E. J. Gheury de Bray has proposed and defended the suggestion that the velocity of light may be a decreasing function of time, varying at present by about 4 km. a second a year. He bases this idea on an examination of the published results of measurements by a number of experimenters over a period of several decades, and concludes that all the results are in good agreement with his hypothesis.

I have obtained experimental proof that no such variability of velocity exists; the work was an offshoot of an investigation carried out at the California Institute of Technology to test whether time conforms to the requirements of the theory of relativity. An interference arrangement was employed in which the retardation of the interfering beams was 318 mm. or 582,000 wave-lengths of the mercury line used as the source. It proved feasible and easy to measure shifts in the interference pattern with a probable error of a thousandth of a fringe. This accuracy was attained by photographing the interference rings and comparing each photograph directly with a nearly identical one used as standard of reference for the whole series. The interference apparatus was built almost entirely of fused quartz and kept in a vacuum at an accurately controlled temperature, while the source, which was an electrodeless high-frequency discharge in unsaturated mercury vapour, was so contrived as to be free from spurious frequency shifts such as might result from Doppler effects, pressure variations, and so forth. The apparatus and procedure are described in detail in a paper entitled "Experimental Establishment of the Relativity of Time", by myself and E. M. Thorndike, to appear in the *Physical Review*.

The number of waves retardation in any interference arrangement is

$$n = \frac{\nu \Delta s}{c}$$

where ν is the frequency and c is the velocity of light, while Δs is the path-difference. If ν and Δs are supposed constant while c is a function of time, the rate of variation of n is thus

$$\frac{dn}{dt} = -\frac{\nu \Delta s}{c^2} \frac{dc}{dt}.$$

$\Delta s = 318$ cm., $c = 3 \times 10^{10}$, $\nu = 6 \times 10^{14}$, and according to de Bray's hypothesis $\frac{dc}{dt} = -4$ km. per sec. per year $= -1100$ cm. per sec. per day. Hence we should find

$$\frac{dn}{dt} = 0{\cdot}023 \text{ fringe per day.}$$

Three series of data were taken over periods varying from 8 days to a month, and the computed daily rates of change, expressed in thousandths of a fringe a day, are $0{\cdot}050 \pm 0{\cdot}020$, $0{\cdot}007 \pm 0{\cdot}013$, and $-0{\cdot}015 \pm 0{\cdot}021$. Their mean is $0{\cdot}014 \pm 0{\cdot}011$. This value stands in the ratio 6×10^{-4} to the amount required by the hypothesis of variable velocity, and of course definitely disposes of the possibility of it, unless the frequency itself is supposed to vary correspondingly.

Seattle, July 5.

Metabolic Rate and Habitat

WHILE innumerable adaptations in structure and habits of animals have been described, we have as yet little knowledge of the physiological causes and effects of distribution and habitat.

As regards metabolism, it is known that trout and mackerel, fishes confined to well-oxygenated waters, have hæmoglobins with a relatively small affinity for oxygen.[1, 2] Their blood cedes its oxygen readily to the tissues, permitting of an active life, but in water deficient in oxygen these fishes suffer. Carp, on the contrary, lead a sluggish life. Their hæmoglobin parts reluctantly with its oxygen, but it can capture the gas from poorly aerated waters and so enable the fish to survive. Trout, in effect, consume more oxygen than carp.[3, 4] The squid and the king crab offer a like contrast of blood with hæmocyanins.[5] Again, the oxygen affinity of respiratory pigments varies with temperature, and this circumstance may limit poikilothermal animals to different latitudes.[6]

Some marine invertebrates can live in brack[illegible] water, and it has been shown that these ani[illegible] sume more oxygen in the fresher wat[illegible]

sea.[7, 8, 9] This suggests that freshwater animals may necessarily have a higher metabolic rate than their marine relatives. Data, however, are lacking on this score. We have therefore compared the oxygen consumption of marine and freshwater amphipods and isopods. To obtain significant data, nearly related anæsthetised animals of the same size and sex were used. We have found that the metabolic rate of the freshwater species *Gammarus pulex* is 1½ times that of the marine *G. locusta* and *G. marinus*; and the metabolic rate of the freshwater *Asellus aquaticus* is 3 times that of the marine *Idotea neglecta*.

There is an equal absence of physiological data concerning freshwater animals limited in their distribution to swift streams and to still waters. Comparing the oxygen consumption of the larva of the mayfly *Bœtis rhodani*, an animal living in rapid streams, with that of its pond relative *Chlœon dipterum*, we find that the former has a value 3·4 times the latter. Moreover, the rates of their heart beats are as 3 : 1. Again, the metabolic rate of the caddis worm *Hydropsyche* sp., from rapid streams, is 1½ times that of *Molanna* sp., from ponds. Finally, an unexpected difference in oxygen consumption was found between members of one and the same species from two such habitats. The ratio of the metabolic rate of *Asellus aquaticus* from a swift stream to that of members of this species from slow water is as 3 : 2. It is hoped that breeding experiments will decide whether the last-mentioned difference is inherited or not.

Nitrogen Requirements of the Lactic Acid Bacteria

IN view of the importance attached by Orla-Jensen to the nitrogen source employed in the study of the lactic acid bacteria—an importance emphasised by the results of our own studies—we have investigated the nitrogen distribution in some thirty-seven sources of nitrogen, and have determined the influence of these sources on the production of acid from glucose, mannose, and lactose by five strains of lactic acid streptococci after fourteen days' incubation at 23° C. For the nitrogen distribution determinations we used the method of Wasteneys and Borsook. In the subsequent preparation of the sugar broths for the fermentation work and in the recording of the results we proceeded after the manner of Orla-Jensen. Certain of the nitrogen sources investigated are available commercially; many, principally peptic, digests of casein and some tryptic digests of casein, are such as may readily be prepared by laboratory workers.

Each of the streptococcus strains studied produces an amount of acid comparable with that produced by certain strains of *Sc. cremoris* when a peptic digest of casein, 1 per cent total nitrogen content, is used as the nitrogen source; the broth thus prepared containing 57·69, 20·36, and 17·39 per cent of proteose N, peptone N and sub-peptone N respectively. If the total N, content be 0·5 per cent, the total ...able acidity is not more in each case than from ... to one-third the amount already cited. A ... digest containing 1 per cent total nitrogen proves to be quite unsuitable as a nitrogen source for each of the organisms under study. When the total nitrogen content is 0·5 per cent, however, two strains are still feeble in the production of acid, but three strains produce from 6·0 to 8·6 grams acid (calculated as lactic acid) per mille. The tryptic casein digest broth contains 0·0, 27·68, and 69·82 per cent proteose N, peptone N, and sub-peptone N respectively. A commercial 'hydrolysed casein' broth prepared to contain 1 per cent total N shows an analysis of 35·84 per cent proteose N, 27·26 per cent peptone N, and 32·08 per cent of sub-peptone N. As a source of nitrogen this broth is very suitable for each of the five organisms, and particularly suitable for the three strains that, as described above, respond to a tryptic casein digest. Our results indicate that in fermentation studies on the lactic acid streptococci both the 'kind' and the 'amount' of nitrogen employed are critical.

This study is one of a series on cheese-ripening provided for by a research fund established jointly by the University of British Columbia and the Empire Marketing Board. A complete and detailed account of the work is in press awaiting the next issue of the *Journal of Dairy Research*, Cambridge.

Occurrence of the Cyclopoid, *Herrmannella rostrata* Canu, in *Cardium edule*

WHILST examining *Cardium edule* isolated in bowls and obtained from Morecambe Bay, Lancashire, Prof. Orton found an abundance of copepods and gave them to me for examination.

The copepod proved to be *Herrmannella rostrata* Canu,[1] one of the Lichomolgidæ leading a semi-parasitic existence in the cockle. When the cockles were opened separately in finger-bowls in the laboratory many of the copepods were clearly seen to leave their hosts; they appeared to be distributed throughout the mantle cavity but showed a tendency to congregate round the siphons. Tow-nettings from gulleys on the cockle beds in Morecambe Bay revealed a number of *Herrmannella* swimming actively in the sea-water amongst various Calanoids and other planktonic material. Males and females with and without egg sacs were seen both in the cockle and swimming freely.

Canu records *Herrmannella rostrata* from the mantle cavities of *Cardium edule* L., *Mactra stultorum* L., and *Pecten opercularis* L., from the French coast, but there does not appear to be any record of its being found in British waters. As it is so very abundant in *Cardium* from Morecambe Bay, it seems unlikely that it is of merely local occurrence, but possibly has been mistaken for *Lichomolgus agilis* (Leydig), a species which it closely resembles and which has been recorded from *Cardium* from many localities and from Lancashire by Thompson.[2] Sars, Canu, and many other writers[3] record *L. agilis* only from the Nudibranchiata.

Habits of the Toad, *Ceratophrys*

A MISHAP which throws additional light on the voracious habits of the South American toad *Ceratophrys* deserves to be put on record. Four of these creatures were received here at the end of June and at the same time two small alligators. When they came, only one vivarium was ready for use, and for a week the toads and alligators shared accommodation in it. They appeared to ignore one another and to be perfectly content. The alligators spent much of the time basking on the top of a small wooden penthouse or immersed in the water trough: the toads dug themselves comfortable burrows and were soon effectively concealed. Both took the food that was offered to them, the toads showing an appetite for the common frog and the alligators for a diet of beef and worms.

Meanwhile a new vivarium was prepared. But when the day came to transfer the alligators to it, it was found that one of them had completely vanished during the previous night. A thorough search revealed no trace of the missing animal, and the suspicion grew that one of the toads was responsible for its disappearance. On the pampas they are reputed to steal chickens, and Gadow reports an instance of cannibalism even, on the part of one of a pair sent to him by a friend (cf. Cambridge Natural History—"Amphibia and Reptiles", p. 217). The four toads in this case were subjected to a screening examination with X-rays, and in one of them a large dark shadow distinctly disclosed the presence of the missing alligator. The length of the alligator was 11 in. over all (head 2 in., body 3 in., tail 6 in.). Its maximum breadth was 1¼ in. The corresponding dimensions of the toad are: length 6 in., maximum breadth 3½ in.

It remains to be said that the toad is digesting its unusual meal with the utmost complacency.

The Andean Eruption and Sunset and Sunrise Glows in South Africa

THE first sunset glow due to volcanic dust from the Andean eruption was seen in Cape Town on April 21. The glow, which was of remarkable intensity, started about fifteen minutes after sunset and lasted fully an hour, the colour being a deep fiery red. There were many inquiries that evening at the *Cape Times* office and at the Central Fire Station whether a large fire was raging in the suburbs; there were also numerous telephonic inquiries at the Royal Observatory as to the cause of the phenomenon. I therefore gave a statement to the *Cape Times*, which appeared in the following morning's paper, attributing the phenomenon to volcanic dust from the Andean eruption, and anticipating that it would be followed by sunrise and sunset glows for several weeks.

The glows have continued to be visible in Cape Town up to the present time, eight weeks since the appearance of the first glow, with varying but on the whole decreasing intensity. None, however, has been so striking as the sunset glow on the evening of April 21 and the sunrise glow the following morning.

I have collected some information as to the region over which the glows have been visible. It appears that they have been generally observed throughout the Union of South Africa and the Bechuanaland and Basutoland Protectorates. The effects appear to have been even more striking in the clear air of the Karroo and the high veldt than here. At Mafeking, one month after the appearance of the first glow, a trustworthy observer stated that the glow was of a fire-red colour stretching right across the sky, even long after darkness.

The speed of the easterly moving current of air which carried the volcanic dust across from South America would appear to be about twelve miles per hour.

Aurignacian Flint Implements from Raised-Beaches underlying the Brown Boulder Clay

RECENTLY, in conjunction with Mr. J. Reid Moir, I recorded my discovery within the Thames valley of a Middle Mousterian occupation-floor overlain by gravel and brickearth (70 ft. above O.D.) and post-dating the formation of the Coombe Rock.[1]

I have since been engaged in a series of excavations in the estuarine gravels at Kirmington (90 ft. above O.D.) and to the west of Barton-on-Humber, Lincolnshire (50 ft. above O.D.). At both these sites the Brown Boulder Clay caps the estuarine gravel.

In addition to derived artefacts belonging to earlier periods, these estuarine gravels contain implements of Aurignacian age likewise exhibiting a rolled condition.

These specimens will be described before the Society of Antiquaries of London in November next.

Research Items

Fossil Man of Asselar (Sahara).—A study of a fossilised human skeleton, discovered at Asselar, Cercle de Kidal, French Sudan, in 1927, has been published by MM. Marcellin Boule and Henri Vallois (*Mém. 9, Arch. Inst. Paléontologie humaine*). The palæontological and geological data of the discovery, though the latter are to some extent a matter of inference, warrant an Upper Pleistocene dating (Europ. Âge du Renne), and point with certainty to a period when the Sahara was well watered. No implements were found associated with the skeletal remains, but surface finds of upper palæolithic, mesolithic, and neolithic types, obviously later in date, were made not far away. The skeletal remains were neither water-borne nor buried, and appear contemporary with the fauna, now extinct in the area, found in identical deposits nearby. The skull, including the face, is well preserved. The principal parts of the skeleton which are missing are about two-thirds of the femora and tibiæ. It is probably the skeleton of a male of at least forty and possibly more than fifty years of age. The most striking characteristics are the dolichocephaly of the skull, the broad and dysharmonic face, platyrhiny, the size of the teeth, and primitive features in the jaw. The cephalic index is 70·9. The skull is high and the cranial capacity approximately 1520 c.c. There is distinct sub-nasal prognathism, though this character is not specially marked when the face is taken as a whole. When compared with other types of early and recent man in Africa, Asselar man is seen to resemble most closely types found in South Africa, especially the Hottentot and Bantu, more particularly in the features in which these can be regarded as unspecialised and primitive. It is suggested, therefore, that Asselar man and Grimaldi man are derivatives, perhaps to be associated with the Capsian industry, from an earlier less specialised type, which divided, one branch going north and evolving in the direction of Cro-Magnon man, while the other, going south, became the ancestral type of the Bushmen and the less specialised Hottentot.

The Royal Tombs, Monte Alban, Southern Mexico.—An interesting article by Mr. Herbert J. Spinden on the recent discovery of a treasure of gold in one of the tombs opened by Dr. Alfonso Caso on Monte Alban, Southern Mexico (*Brooklyn Mus. Quart.*, vol. 19, No. 2), stresses the cultural evidence of the finds as of more importance than their intrinsic value. For example, they bear out the derivation of metal, gold and copper, and the methods of working metal among the ancient inhabitants of Mexico from Colombia and Costa Rica. One of the interesting facts which emerge from the Monte Alban finds of gold ornaments is that the paddle-shaped feet-of-frog amulets from Costa Rica contribute to the shape of elaborate Mexican amulets dealing with very different subjects, such as a remarkable piece with dates on the flanged base. Mr. Spinden is unable to follow Dr. Caso in his attribution of these tombs to Mixtec temporarily in occupation of Monte Alban. He himself is of the opinion that they are Zapotec and that the site is the ancient Zaachila, famed as the capital of the Zapotecs, and called Teozapotlan by the Mexicans. This opinion is based very largely on the character of the architecture of the tombs, which are regarded as comparable to others which have been excavated on Zapotecan sites at Xoxa and Cuilapa; but the engraved human ...es found in heaps in the treasure tomb are certainly ...s to Mixtec work, and are probably connected ... cults of the Jaguars and Eagles. As it is clear, Mr. Spinden thinks, that ...eramics fall before the last pre-Spanish period, and after, rather than before, Toltec times.

Damage by Deer and its Control.—In Scotland, damage to crops by deer is a desultory and not very extensive occurrence, but in California the last decade has seen the problem gradually gaining in economic importance, until the State departments concerned have been compelled to take up the matter of control. One line of investigation prosecuted by Gordon H. True promises good results where damage is extensive, that of determining the efficiency of repellants (*California Fish and Game*, p. 156, 1932). The repellants tested consisted of various chemical substances playing upon the senses of smell or taste, and physical devices intended to play upon the natural wariness of the deer. It may be said at once that the latter, of the scarecrow or automatic flash gun type, soon lost any scaring effect they may have possessed at first. But the dusting or spraying of various chemical substances produced good results. For example, the spraying of blood upon orchard trees afforded 50-100 per cent protection. Other materials used were the proprietary *D4*, a mixture of whale-oil soap and liquor cresolis, naphthalene flakes, asafœtida, and each of these proved effective to some degree, although creosote and creosote dips met with little success. It was found, however, that the effectiveness of any repellant depended upon a number of conditions, such as temperature, rainfall, intensity of deer population, and the situation of crops to be protected with reference to wild country. So that a substance successful in one case may prove a failure in another. But the author is of opinion that where deer are causing extensive losses, the saving brought about by the use of repellants will more than counterbalance the cost.

Hybrid between Wolf and Dingo.—From a correspondent we learn that pairing between a male European wolf and a female Australian dingo in the Adelaide Zoological Garden resulted in a litter of six hybrid pups, all female. The hybrids more resemble the dingo than the wolf, and one has been sent to Melbourne Zoological Gardens for further experiments in hybridisation. Although it is stated that the cross is a rare one, if indeed it is not unique, the fact that dingos breed freely with the domesticated dogs of the settlers makes it not unlikely.

Madras Medusæ.—Mr. M. G. K. Menon, in a paper, "The Hydromedusæ of Madras" (*Bull. Madras Gov. Mus.*, New Series—Nat. Hist. Sec., vol. 3, No. 2, 1932), investigates the species from the surface layers of the shallow waters off Madras within three miles of the coast, the collections being made every other day, early in the morning, for a year. Out of 35 species obtained, belonging to 28 genera, 6 are new and there is one new genus. Most of the medusæ recorded are littoral, and there is every reason to think they were generated on the coast. After a general dearth of organisms in the sea in the late summer, roughly corresponding to the hottest time of year, an outburst of planktonic growth takes place and the hydromedusæ begin to appear, steadily increasing until January, in which month the maximum is recorded. After March there is a steady decline in numbers and, with few exceptions, a scarcity of species. The present collection adds considerably to our knowledge of the medusæ of the Indo-Pacific, and it is interesting to find such typical Atlantic species represented as, for example, *Amphinema dinema* and (probably) *Leuckartiara octona*. The author notices that in the canal system of some examples of *Æquorea parva* a number of radial canals have lost their connexion with the stomach and

have developed on their ventral surfaces openings surrounded by minute lips which are capable of functioning as accessory mouths. This is in agreement with *Mesonema pensile*, in which Browne observed that the canal system had taken on the function of the stomach, in this species the lower wall of the stomach being quite rudimentary. Browne has suggested that this may apply to other Æquoridæ and account for the large number of radial canals and excretory pores on the circular canal.

Crystalline Style in Large Molluscs.—The crystalline style which occurs in all bivalves and in many herbivorous gastropods is usually a gelatinous rod continually being secreted in a style sac and pushed forward so that its free end is in the stomach, where it is dissolved and sets free a powerful amylase and an oxidase. Dr. C. M. Yonge (*Proc. Malac. Soc.*, **20**, pt. 1, pp. 44, 45, March 1932) has examined the largest living bivalve, the giant clam, *Tridacna derasa*, on the outer reef of the Great Barrier Reef of Australia, and found that the style was 34 cm. in length and 0·5 cm. in breadth. The style had to be preserved in strong alcohol for two days before there was opportunity to weigh it accurately, and its weight was no doubt substantially reduced by this dehydration; its weight was then 3 gm. The length of the *Tridacna* from which it was obtained was 3 feet. At Bermuda, Dr. Yonge examined *Strombus gigas*, the largest of the herbivorous gastropods, which feeds on fine filamentous algæ, and found that in specimens 11½ in. and 10 in. long the respective styles were 22·25 cm. and 20·6 cm. long and 0·6 cm. broad, and weighed 2·8 gm. and 2·5 gm.

A Braconid Parasite of the European Corn Borer.—*Technical Bulletin* No. 294 (May 1932) of the U.S. Department of Agriculture is entitled "The Biology and Morphology of the Braconid *Chelonus annulipes* Wesm., a Parasite of the European Corn Borer", by Mr. Arlo M. Vance. The genus *Chelonus* includes a large number of species, many of which occur in Britain, but little detailed study of any of its members has been undertaken. The species in question parasitises the European corn borer (*Pyrausta nubilalis*) in Italy, and the present investigation has been made in connexion with its introduction into the United States, where the corn borer is well known as an immigrant pest of first importance. Mr. Vance gives a very thorough account of the external and internal structure of the *Chelonus* larva. The most notable feature seems to be the absence of Malpighian tubes, usually present in hymenopterous parasites. Small outgrowths, or buds, originating from the hind intestine, are considered to be rudiments of these organs. The process of excretion appears to be performed by special urate cells found in the fat body. The female *Chelonus* deposits an egg in that of the corn borer, and the larva passes through three instars within the growing larva of the host. At its last stage the parasite larva leaves its host and, after devouring the remaining tissues of the latter, spins a cocoon and pupates. At a constant temperature of 77° F. two days are required for the incubation of the parasite egg, about 20 days are occupied in larval development, and 9½ days are passed as a pupa. The period from egg to adult is estimated to require about forty days in the field.

Sclerotial Diseases of Rice.—Messrs. Malcolm Park and L. S. Bertus are working at the Royal Botanic Gardens, Peradeniya, Ceylon, upon the sclerotial diseases of rice (*Ann. Roy. Bot. Gardens*, **11**, pt. 4, pp. 319-332 and pp. 343-359; 1932). *Rhizoctonia* (*Corticium*) *Solani* not only gives trouble in the potato fields of England, but also causes a disease of rice in Ceylon. The symptoms of the malady are described in the first paper, and the characteristics of the fungus in pure culture are noted. Practical aspects of control have been considered, but, owing to the longevity of sclerotia in soil, the ordinary methods of crop rotation are inadequate. Experiments are to be directed towards finding a specific soil treatment. The other disease investigated is caused by *Sclerotium Oryzæ*, and has been studied with as much detail as the *Rhizoctonia* malady. It is possible to grow varieties of rice which are resistant, but irrigation water should never be allowed to flow through a diseased field, since it might carry infection. The disease occurs in patches in the rice-growing areas, and the crop growing on the patches should be burned at harvest time.

Gas without Oil.—The phenomenon of extensive accumulation of natural gas without associated petroleum is not by any means new, especially in certain parts of the United States and Canada. A somewhat unusual example is furnished by the Jackson Field, Mississippi, where a daily open flow of gas totalling 1,250,000,000 cubic feet from 42 wells has been estimated. The actual amount drawn from the field last year was about 13,000,000 cubic feet a day, a comparatively small proportion of available supplies. This gas has a high calorific value and contains a large percentage of methane—in one case 64·45 per cent, in another case 90·23 per cent; other constituents are ethane, carbon dioxide, and nitrogen, the latter in sufficient quantity to suggest a possibility of helium content, though the report of this area by Mr. Watson H. Monroe (*U.S. Geol. Sur.*, Bull. 831-A, 1931) makes no specific mention of this.

Coal of the Northumberland Area.—The Department for Scientific and Industrial Research has issued Paper No. 22 of the Physical and Chemical Survey of National Coal Resources, dealing with the 'Main Seam' of the Northumberland Area (London: H.M.S.O. 1*s*. 6*d*.). The report contains detailed analyses of samples taken from 16 points over the whole area, which is an important one, producing 50,000,000 tons annually and largely for export. The coal is frequently of high quality, but varies in caking properties. The association of a high sulphur content where the caking properties are good has prevented the development of a Northumberland coking industry. The coals are marketed primarily for home and steam purposes.

International Colorimetry.—The discussions which have been going on for some time in Great Britain and other countries as to the best method of measuring and specifying colour have for the present been settled by the decisions of the International Illumination Congress which met in September last at Cambridge. A report and discussion of these decisions by Mr. T. Smith, who was chairman of the Committee on Colorimetry, and Mr. J. Guild appear in part 3 of vol. 33 of the *Transactions of the Optical Society*. The trichromatic specification of colours is to be adopted as the standard one, but the three primary colours are to be such that the amounts of each necessary to match a colour occurring in practice shall always be positive. This involves a departure from the system of primaries adopted previously by the National Physical Laboratory, the R, G, and B of which were the spectral lines 7000, 5461, and 4358 respectively, and the equations specifying R, G, and B and the standard white light in terms of the international primaries are given. The standard white is that transmitted from a gas-filled incandescent lamp operating at a colour temperature of 2848° absolute through two blue solutions of specified compositions.

Optical Diffraction by Sound Waves.—Sup[illegible] waves in liquids have a space periodi[illegible] small to be comparable for diffract[illegible]

the wave-length of light, and if the density changes are sufficiently large, should be able to act as a grating. This effect, which was predicted by Brillouin, has now been observed by P. Debye and F. W. Sears (*Proc. U.S. Nat. Acad. Sci.*, June 15) and made the basis of a method for finding the speed of supersonic waves, the wave-length being found by the optical experiment in terms of the wave-length of light, and the frequency by a radio wave-meter. The theory is not given in full, but leads to the ordinary diffraction formulæ, so far as the angular deviation of the light is concerned. The diffraction pattern in its higher orders provides a test of the constancy of the speed of the supersonic waves. By measuring the intensity of the diffracted beams when the light is passed through the liquid at different distances from the source of the waves their attenuation can be calculated, but so far has been found to be appreciable only for glycerine, which probably acts in this way from its high viscosity.

Optical Absorption of Solutions of Sulphur.—An example of the value of a study of optical absorption spectra for obtaining information concerning the molecular condition of a dissolved substance is given by Prof. Campetti in a paper published in parts 6-10 of the *Rendiconti* of the Reale Istituto Lombardo di Scienze e Lettere for 1932 (vol. 65). Results are given of determinations of the absorption limits for solutions of sulphur in *m*-xylene and carbon tetrachloride at temperatures ranging from 20° to 130°. The curves connecting the limits of absorption (ordinates) with the concentrations of sulphur in the two solutions at any one temperature intersect near the absorption axis. If, however, the initial ordinate is made the same for both curves, the curve for the carbon tetrachloride solutions lies wholly above that for the *m*-xylene solutions, so that a given weight of sulphur dissolved in the former solvent exerts a somewhat greater absorbing effect than when dissolved in *m*-xylene. Since the formation in solution of molecular groups of greater complexity than S_8 is improbable, the obvious and almost necessary explanation of such behaviour is that sulphur and *m*-xylene give rise to molecular associations with absorption less than the sum of those of the components separately. This conclusion appears to be related to the fact that, at temperatures which are not too high (about 195°), the two liquids—liquid sulphur and *m*-xylene—are miscible in all proportions.

Astronomical Topics

New Comet.—A comet of magnitude 7½, visible in an opera glass, was discovered independently by Mr. L. Peltier at Delphos, Ohio, and by Dr. Whipple photographically at Harvard. It is Mr. Peltier's third cometary discovery and Dr. Whipple's first, though his name is very well known as a cometary observer and computer. He and Mr. L. E. Cunningham have computed the following orbit for the comet:

$$\begin{array}{ll} T & 1932 \text{ Sept. } 1{\cdot}510 \text{ U.T.} \\ \omega & 38°\ 10' \\ \Omega & 344\ \ 40 \\ i & 71\ \ 49 \\ \log q & 0{\cdot}01662 \end{array} \left.\begin{array}{l} \\ \\ \\ \end{array}\right\} 1932{\cdot}0$$

The comet is in high northerly declination, and visible all night; an ephemeris is given for 0^h U.T.:

	R.A.	N. Decl.
Aug. 21	$4^h\ 7^m\ 20^s$	64° 51′
25	5 5 12	73 38
29	7 5 58	79 22
Sept. 2	9 57 36	79 47
6	11 44 44	76 22
10	12 35 45	72 12
14	13 3 14	68 16

The following observations have come to hand; the first is by Mr. Möller at Copenhagen, the others by Dr. W. H. Steavenson at Norwood:

U.T.	R.A. (1932·0).	N. Decl.
Aug. $10^d\ 23^h\ 7^m\ 18^s$	$3^h\ 11^m\ 35{\cdot}25^s$	38° 27′ 27·6″
11 23 42 24	3 14 54·41	41 8 11·2
12 23 21 15	3 18 25·16	43 45 15·8
13 23 39 5	3 22 22·52	46 27 35·7

Dr. Steavenson saw a short tail, the shape of which resembled that of Halley's comet in miniature; it made a considerable angle with the radius vector produced.

Observations of Radio Signals during the Eclipse.—A Science Service Bulletin, dated July 25, invites the co-operation of all who have means of estimating the strength of radio signals in observing the effect of the eclipse on these signals. In a letter in NATURE of May 21, p. 757, Profs. S. Chapman and E. V. Appleton pointed out that the radio effect may be expected to precede the optical eclipse by two hours, so that the British Isles come within the affected region; observations should be continued during the whole of [illegible] of Aug. 31, but it is in the latter part [illegible] effect is to be looked for. The main [illegible]ation is to test theories about the upper and lower Heaviside layers; one theory ascribes both layers to the action of ultra-violet light from the sun; the other theory ascribes the lower layer to neutral particles streaming from the sun. In the former case the effect would be limited to the regions of optical eclipse; but in the latter view the slower motion of the particles would cause an eastward shift of the radio eclipse compared with the optical one. Also the streams of particles are supposed not to come from the whole sun, but from special regions; this would make the region of radio eclipse as broad as the diameter of the moon, as contrasted with the hundred-mile width of the zone of optical totality.

Lunar Computations for the *Nautical Almanac*.—An article by Dr. L. J. Comrie (*Mon. Not. R.A.S.*, May) illustrates in a vivid manner the immense aids to astronomical calculations that have been afforded by mechanical inventions in the present century. Prof. Brown's Lunar Tables were introduced into the almanacs for 1923. More than 1400 periodic terms are tabulated, and the computations up to the present have involved the continuous work of two skilled computers. Dr. Comrie noticed that much of the work could be facilitated by the use of the Hollerith tabulating machine, and was instrumental in obtaining the hire of a machine for the office of the *Almanac*; by its aid it has been possible to carry out the larger part of the lunar computations for the remainder of the present century at an aggregate cost of less than a quarter of what it would have been on the old method, and with considerably greater security against error. The details of the process are described in the paper. The first stage is to divide the period of each harmonic term into an integral number of parts, so chosen that the motion in a day is an integral number of these parts; the next stage is the preparation of cards, which are punched with holes in different columns, the height of the hole in each column indicating the corresponding digit. The cards for each harmonic term are then arranged in stacks. The top cards of each stack, representing the first date, are collected by hand into another stack; the addition of harmonics is performed by the machine, and the result printed. An important feature is the sorter, which automatically arranges the cards in groups according to the numbers punched in any selected column. The result is easily checked, since all the cards in each stack have a hole in the same place, so that there is a tunnel right through the stack.

The University of Rangoon

By Prof. D. H. PEACOCK

IN July 1931, the University of Rangoon held its annual Convocation for the first time in the new Convocation Hall, the Training College opened its new buildings, and in November of the same year University College and Judson College moved into the science wings of their new buildings, of which the arts wings had already been in use for some time. The work of building the University of Rangoon is thus virtually complete.

The buildings in existence in 1920 were quite unsuited to the needs of a modern university, and while the constitution of the new University was under consideration, tentative projects for new buildings were drawn up. Sir Spencer Harcourt Butler, when Lieutenant-Governor of Burma, had wisely reserved a site of some four hundred acres about five miles from Rangoon on the southern shore of the Victoria Lake, and, in December 1922, Sir Reginald Craddock, Lieutenant-Governor of Burma, laid there the foundation stone of the new Convocation Hall. No provision had at this time been made for funds for the new buildings and no body had been authorised to carry out the work, but both matters received early attention from Sir Spencer Harcourt Butler, who returned to Burma as Governor in January 1923. In 1925 the Government of Burma constituted a Building Trust of fifteen members, of whom four were elected by the University, to carry out the erection of the University buildings with the exception of the Medical College. The full-time services of Mr. M. J. Sheehy were placed at the disposal of the Trust as executive engineer, and as occasion arose the Trust was also able to utilise the services of Colonel Longdin and Mr. C. C. Codrington for the water supply, sanitation, and mechanical ventilation and of Mr. Eades for the electrical installation. The first chairman of the Building Trust was Sir Robert Giles, and he was succeeded by Sir Oscar de Glanville, who has completed the work. The University is also greatly indebted to Sir Charles Innes, Governor of Burma since 1928 and Chancellor of the University, to whose sympathetic consideration is largely due the provision of the necessary funds, and to Sir Benjamin Heald, Vice-Chancellor of the University.

The Government of Burma set aside a sum not exceeding £780,000 for the buildings and their ancillary services. The Building Trust had not only to erect new buildings for the existing colleges—University and Judson—but also to build a Convocation Hall for the University, a Training College for Teachers, and houses for the staff and servants of the colleges and the University. In addition, much that is usually provided by local authorities had to be provided by the Building Trust; roads had all to be made, wells had to be sunk and a waterworks erected, and septic tanks and a complete system of sanitation had to be provided. It should be mentioned that the American Baptist Mission defrayed half the cost of the erection of Judson College.

FIG. 1.—University College, Rangoon.

The Convocation Hall, the buildings of University and Judson Colleges, and the Training College for Teachers are of steel-framed brick coated with white plaster. University College (Fig. 1) consists of six blocks of buildings joined by a colonnade running north and south. The College Library is one hundred and forty feet long and thirty feet wide, and behind it are the College Hall and students' common rooms. On either side of the library block are the north and south arts wings; each is a three-storied building approximately two hundred and fifty feet long and forty feet wide. At the back of the College are the three science wings, which are of the same height and exterior appearance as the arts wings. The north science wing contains the physics department and, on part of the top floor, the geology department. The middle wing is devoted to the chemistry department. The south wing contains the departments of forestry, botany, and zoology and the institute of helminthology. All the science wings are approximately two hundred and twenty feet long, the north and middle wings forty feet wide, and the south wing is thirty feet. Communication to rooms in all the te...

by a deep verandah on the south side. All windows and doors are steel-framed; the floors are for the most part parquet floors of Burmese teak. The verandah floors, however, and the floors of some of the laboratories are of salemite. The physics and chemistry laboratories deal with some four hundred students a week, the majority being pre-intermediate students. Post-graduate work is undertaken by very few students. The buildings of Judson College are similar in plan to those of University College but smaller.

The College buildings are separated by a short distance from their hostels. University College has eight men's hostels, each able to accommodate about one hundred and twenty students and managed by a warden, an assistant-warden, and tutors. Five of these hostels have a central dining-hall, while the other hostels have their own dining-halls. The hostel fees of men students, which include board and lodging, amount to about £2 a month. In addition to these hostels for men, there is a hostel for women students, which accommodates about one hundred and twenty students and is managed on similar lines to the men's hostels. Judson College has two men's hostels and one women's hostel, all similar in construction to those of University College. All except three of the hostels are built of red brick and were designed by Mr. S. P. Bush, Government architect, Burma. The hostels of all the colleges can together accommodate about 1300 men students and about 300 women students. Both Colleges have large playing fields.

The University Convocation Hall is situated near the lake front at the north end of the estate, with the main buildings of University and Judson Colleges to east and west of it. It can hold some two thousand people and is one of the most striking buildings in Rangoon. It is a steel-framed brick building coated with cement plaster, and has a parquet flooring of Burmese padauk and is panelled with yinma, one of the most beautiful of the lighter-coloured Burmese hardwoods. The main doors are of bronze and open on to marble steps covered by a bronze marquise. The Convocation Hall, the main buildings of University and Judson Colleges, the University Library, and three of the University College hostels were designed by Mr. T. O. Foster.

The University Library was the gift of a generous donor who did much for the cause of education in Burma, Raja Dr. Reddiar, and has been built at a cost of some £15,000. The bookstack is to be fitted with an air-drying plant which will be, so far as is known, the first of its kind to be used in any library. The colleges already possess quite well-stocked general libraries, and the University Library is being devoted mainly to Oriental studies, including language, history, and art. In this connexion, University College has established a lectureship in Far Eastern history, and a considerable amount of work is being done in the University on the history of Burma.

The University Students' Union building and the University gymnasium, both designed by Mr. T. O. Foster, were the gifts respectively of Dr. Tun Nyo and Mr. Ch... Chor Khine. Both buildings are well equipped for the purposes for which they are used.

The Teachers' Training College, designed by Mr. Armstrong, is situated in the southern part of the estate, and in addition to administrative and teaching buildings and hostels for men and women students, contains two practising schools, one for boys and one for girls, each with hostel accommodation for resident pupils. Provision has also been made for training in kindergarten work, and it is hoped that the College will supply what is the most urgent educational need in Burma, namely, well-trained teachers for the schools. The normal schools did excellent work in the face of great difficulties, but they lacked the resources now at the disposal of the Training College.

The engineering department of University College is housed in a set of buildings some half-mile distant from the main College buildings. For their erection a most munificent donation of £100,000 was made by the Burma Oil Company, and part of this donation has been used as an endowment towards the necessarily heavy expenses of upkeep.

Housing accommodation for the staffs of the constituent colleges and of the University has been provided by the Building Trust, which also has built a sanatorium for the students, a book-shop, a post office, a village for the servants of the colleges and the University, and quarters for the staff of the University training corps.

The Late Palæolithic Inhabitants of Palestine *

THE skeletal material of late palæolithic age from Palestine, upon which Sir Arthur Keith reported to the International Congress of Prehistoric and Protohistoric Sciences at a meeting held on Aug. 3, was collected by Miss Dorothy Garrod from deposits in caves at Shukbah in the Judæan Hills in 1928, and on Mount Carmel in 1929, 1930, and 1931. For the industry with which the remains were associated, a new mesolithic industry, Miss Garrod proposes the name 'Natufian', after one of the sites on which it was found. An account of this industry was communicated to the Congress by Miss Garrod at a subsequent meeting held on Aug. 5.

Sir Arthur proposes that the people represented by these remains should also be known by the name of 'Natufian'; for, in his opinion, they were a peculiar people, not to be identified with any living race. They have affinities with the neolithic people of Malta, with the negroid element represented among European peoples in the Aurignacian period, and, more distantly, with the predynastic inhabitants of Egypt and the late palæolithic people of North Africa. Among living peoples they approach most nearly to the Mediterranean race.

At Shukbah, remains of 45 individuals were found—25 adults (9 males and 16 females), 17 children, and 3 adults of indeterminate sex. At Mount Carmel, on the terrace in front of the cave, was a veritable cemetery: 87 individuals were represented—35 adult males, 23 adult females, 23 children, and 6 indeterminate. The proportion of the remains representing a complete skull or skeleton is small. Only 20 individuals afford skull size and shape, and in many cases allowances have to be made for distortion due to pressure.

There are, however, several features which stand out definitely. They were a dolichocephalic people with a cephalic index varying from 72 to 78; they had cap-shaped occiputs; the dimensions of the head are greater than in the predynastic Egyptians. They were prognathous, the sub-nasal prognathism being marked. The nasal bones formed a wide low arch; and the chins were not prominent. Many had big heads.

The stature was low, few men exceeding 1·650 m. (5 ft. 5 in.), most being about 1·600 m.; the women were about 1·524 m. (5 ft.). A striking character is the strong development of the bones of thigh and leg

* ...stance of a paper read before the First International Congress ...and Protohistoric Sciences, London, Aug. 1–6, by Sir ...
...1930]

in contrast to those of the arm, forearm, and shoulder. The thigh bones have a prominent linea aspera, the tibiæ are platycnemic. In more than half the humeri there is a perforation of the olecranon fossa.

Some interesting observations were made on the cultural practices of the Natufians, for which evidence was afforded by the skeletal remains. The two upper incisors of the women were extracted in youth. Evidence for the same practice was found by Mr. Turville-Petre at Kebara, between Shukbah and Carmel. The Natufians also seem to have practised cannibalism. The bones are cut and fractured, the cut and broken surfaces showing that this was done when the bones were in a fresh state. This was at Shukbah only. No evidence of mutilation of the dead was found at Carmel or Kebara.

Evidence of a curious practice was found at Kebara. In the mesolithic deposits were found an assortment of bones which had been burned—not when fresh, but after they had been freed from animal matter by burial or exposure. The bones thus treated, which were collected by Mr. Turville-Petre, represent at least 75 individuals, mostly women. A similar collection had been forwarded to Sir Arthur by Mr. Leonard Woolley, which had been obtained from under the foundations of Ur. Here, too, women's bones preponderated. Further, Miss Caton-Thompson had obtained two skulls (female) from Zimbabwe which had been burned after the flesh had disappeared from the bones. Is this evidence, asks Sir Arthur, of a custom in ancient times of digging up the bones of ancestors and submitting them to the ordeal of fire?

Recent Archæological Field Work in England

THOSE members of the International Congress of Prehistoric and Protohistoric Sciences who elected to join the excursions arranged for the week (Aug. 6–13) immediately following the meeting in London, were fortunate not only in being afforded an opportunity to visit a number of important sites, but also in having demonstrated to them the latest results of this season's work by those who are in charge where excavation is now proceeding.

After dividing into two parties, of which one made its headquarters at Cambridge and the other at Oxford, they rejoined at Salisbury. The Oxford party on the way to Salisbury visited Winchester and Easton Down, near Salisbury. At the latter, they were shown the flint mines discovered from the air by Dr. J. F. S. Stone two years ago, and since excavated by him. The site covers 100 acres, and has a system of V-shaped ditches with deep pits at their convergence, similar to those of Grimes Graves, and containing quantities of half-manufactured implements, antler-picks and shoulder-blade shovels. Within the last few weeks, Dr. Stone has discovered a fresh pit of two courses, each eight feet in depth, with a shallower work nearby, which indicate how the neolithic miner worked.

Among the sites visited from Salisbury by the members of the Congress were the Iron Age fortress on Yarnbury Plateau and the Early Bronze Age site at Windmill Hill, which is being excavated by Mr. Alexander Keiller. At Yarnbury the triple line of fortifications surrounds the largest prehistoric stronghold in Wiltshire. It is 28½ acres in extent, with ramparts 25 ft. high. Within the triple rampart is a single rampart, or rather its remains, and a ditch. Some surprising results achieved in the excavations of the past two months were described by Mrs. M. E. Cunnington. The inner fortifications are not neolithic, as has been thought, but Iron Age work of a period slightly anterior to the triple line. The area was strewn with Romano-British pottery. A cutting in the interior rampart has revealed the post-holes for a chalk revetment sustained against a wooden wall. In the causeway, the only entrance to the fortress, has been found the most impressive Iron Age ditch so far discovered, a V-shaped excavation 12 ft. deep, so acute in angle that it would be impossible for two ranks of attackers to stand on the bottom. In the past few weeks there have also been discovered the guard-house and store-house of the fortress, while above the site of the ditch was the skeleton of a man wearing leather boots with hob-nails and bronze decorative studs.

At Windmill Hill, Mr. Keiller described the results of recent work, which now centres upon the excavation of the outer ditch, some 20 ft. wide and 8-9 ft. deep. Mr. Keiller announced that one-third of the site, which is the largest so far to be observed as included in this type of Early Bronze Age camp, is to be placed in trust for a century so that its excavation may be delayed until the results can be interpreted in the light of the fuller information which will then be available for archæologists.

Submarine Gravity Survey in the Bahamas

AN interesting piece of geophysical investigation has just been completed by an expedition carried out jointly by the United States Navy and the Department of Geology, Princeton University, with the co-operation of the United States Coast and Geodetic Survey. The introduction, in 1923, by Dr. Vening Meinesz of the Dutch Geodetic Commission, of a gravity pendulum apparatus capable of operating on a base not absolutely free from disturbing oscillation, led to the use of a submarine for the determination of the force of gravity over sea-beds and ocean-beds. During the next three years, three voyages in Dutch submarines were made by Dr. Vening Meinesz, and in the course of these he added much to the knowledge of the distribution of the force of gravity over the earth's surface.

In 1928 the United States showed an official appreciation of this pioneer work by inviting Dr. Vening Meinesz to bring his apparatus and carry out a similar investigation in United States waters with the help of a submarine of the U.S. Navy. The cruise was carried out in the autumn of 1928 and covered an area of considerable geological interest in the Caribbean Sea, the Gulf of Mexico, and to the north of Porto Rico. With the land pendulum stations established in that region by the United States Coast and Geodetic Survey, a considerable body of evidence was thus made available for the study of questions of isostatic equilibrium and of tectonic development.

It was a natural consequence that a desire should be expressed by geophysicists for the extension of the investigation to cover the whole of the British West Indies. The consent of the British Government for a submarine of the United States Navy to operate in these waters was obtained, and Dr. Vening Meinesz once more placed his special pendulum appar-

his own services at the disposal of the expedition. The moving spirit in this work, and the director of the expedition, was Prof. Richard M. Field, of Princeton University. He has, since 1922, made a special study of the stratigraphy and structural geology of the continental borders of the Atlantic Basin. In the course of this study he has led three expeditions to the Bahamas region. Dr. Bowie, chief of the Geodetic Division of the United States Coast and Geodetic Survey, was also an active supporter of the expedition. An observer, Lieut. J. P. Lushene, from his department, accompanied Prof. Field in the yacht *Miami*, owned and sailed by Lieut. Hugh Matheson, U.S. Naval Reserve, and made pendulum observations at a number of island stations in the region covered by the submarine party. The U.S. submarine *S.48* Lieut.-Commander O. R. Bennehoff, with Dr. Vening Meinesz on board, left Guantanamo, Cuba, on Feb. 7, 1932, being accompanied by the parent ship U.S.S. *Chewink*, Lieut.-Commander G. A. Miller. In the course of the next two months a cruise of some 4000 miles, in three loops, was made by these vessels, a large number of soundings by the sonic and by the supersonic apparatus were made, and the force of gravity was determined at 53 stations.

This notable expedition was given an international character by appointing advisory committees of prominent persons to deal with the subjects: navigation, geophysics, tectonics, oceanography, sedimentation, marine micro-biology. The Royal Society made a grant of £400 towards the sinking of a bore-hole on Andros Island, Bahamas. In the capable hands of Prof. Field, Dr. Vening Meinesz, and others, the results of the expedition are likely to yield valuable information, not only as to the history of the region, but also in the sphere of tectonics, or the theory of present-day processes in the more active regions in the earth's crust. Gravity survey at sea has come to stay as a major geophysical research, and it is, happily, likely to figure in the not distant future as an object of co-operation between the Navy and scientific authorities of Great Britain.

Calendar of Geographical Exploration

Aug. 21, 1721.—Easter Island

Jacob Roggeveen sailed from the Texel with three ships. On April 6, 1722, he discovered Easter Island, and described for the first time the remarkable stone figures found on that island. A buccaneer, Edward Davis, was reported to have sighted the island in the previous century, but there is no conclusive evidence that he did so. Several other islands were discovered, though it is difficult to identify them from Roggeveen's description: Raiotea in the Society Group was certainly one of them.

Aug. 23, 1683.—A Survey of the Galapagos Islands

A party of buccaneers, among whom were Dampier and Cowley, sailed for the South Seas. They sighted land which they charted as Pepys Island, but which was probably a headland of the Patagonian coast. They were joined by a second ship under Eaton and visited the Galapagos group, where they made a long stay; Eaton and Cowley drew the first fairly accurate chart of these islands, and Cowley's journal long remained the standard authority on them. The islands were discovered by the Spanish in the sixteenth century and received their name from the giant turtles which have evolved there. Charles Darwin found valuable data for his "Origin of Species" in the Galapagos, which he visited in the *Beagle*, a large pro[portion] of the fauna and flora being peculiar to the

Aug. 24, 1499.—Coast of Venezuela

Alonzo de Ojeda discovered the great inland Gulf of Maracaibo, which he called San Bartolomé. Ojeda sailed with four vessels from Cadiz in May 1499, reached Surinam, and coasted past the mouths of the Essequibo and the Orinoco. Rounding the peninsula of Paraguana, they entered a large gulf where they saw pile dwellings, hence they named the gulf and its coasts Venezuela (Little Venice). They passed through the strait to Maracaibo, and after sailing west to Cabo de la Vela, returned home.

Aug. 24, 1897.—Gerlache Strait

Adrien de Gerlache left Ostend in the *Belgica* on an antarctic expedition, Roald Amundsen being mate and Arçtowski accompanying it as geologist. Funds were raised mainly through the personal enthusiasm of Gerlache and his companions; the Brussels Geographical Society opened a subscription list and the Belgian Government gave a small grant. Soundings were made of the hitherto uncharted sea between Cape Horn and the South Shetlands. The strait named after Gerlache, between the Palmer Archipelago and the mainland, was discovered and Graham Land was followed to Alexander I. Land. Finally the vessel was frozen in for the winter in 71° 30′ S. For the first time, a party of scientific workers wintered in the antarctic night; the sun did not appear from May 15 until July 22. The party suffered severely and one died, but scientific observations were steadily continued. The *Belgica* brought back a wealth of data and specimens, and the Belgian Government published the results for which the expedition is justly famous.

Societies and Academies

DUBLIN

Royal Dublin Society, June 28.—**J. Joly**: A suggested mode of radiotherapy when long continued feeble gamma radiation may be desirable. Since all living beings are normally exposed to cosmic radiation, it is conceivable that a comparatively mild increase in the exposure to penetrating radiation might be beneficial in certain diseases. This may be effected by the application of a fabric coated with a radioactive paint prepared by mixing very finely powdered uraninite with acetone containing 10 per cent cellulose acetate. This paint adheres firmly to the surface of the fabric.—**E. J. Sheehy**: Effect of the conditions of storage on the vitamin D potency and on other features of cod liver oil. Storage in transparent bottles, or in tin-lined containers, or in partly filled barrels, does not materially reduce the vitamin D potency. Exposure to light bleaches the oil, whilst exposure to air deepens the colour and increases the rate of production of free fatty acid.—**William Hughes**: A study of *Phoma Lingham* (Tode) Tesm., and of the 'dry rot' it causes, particularly in swede turnips. A number of fungi occur on diseased plants which are considered forms of *Phoma Lingham*, but the one which is exclusively associated with typical dry rot of the roots in Ireland, and is predominant on other organs, is identical with the American cabbage black-leg organism and with Cunningham's Strain II.A from New Zealand. On plants other than swede and turnip, Strain II.B predominated. Strain II.A was the only one which consistently produced dry rot of swedes in the field and laboratory. Strains I.B and II.B (with one exception) failed to do so in the field, while producing a rot in the laboratory. Dry rot may originate from three sources, namely, (1) the seed, (2) from diseased roots of a previous crop which survive in the soil, (3) from similiar roots present in the farmyard manure.

Extensive field experiments, extending over a period of three years, show that infection present in the seed is not capable of producing outbreaks of dry rot so serious as those originating from contamination in soil or manure.

PARIS

Academy of Sciences, July 4 (vol. 195, pp. 1-84).—The president announced the death of Paul Vuillemin, *correspondant* for the Section of Botany, and of Bernhard Bang, *correspondant* for the Section of Rural Economy.—**Henri Lecomte**: Notice on Jean Paul Vuillemin.—**Charles Richet**: Organic memory (elementary memory, anaphylaxy, etc.).—**Charles Achard, Augustin Boutaric, and Fernand Morizot**: A method of studying sera according to their sensitising action in the flocculation of ferric hydroxide.—**C. de la Vallée Poussin**: The properties of harmonic functions in an open domain limited by surfaces with restricted curvature.—**Paul Pascal and André Dupire**: Contribution to the study of the esters of arsenious acid. The method adopted for removal of the water formed during the reaction between the alcohol and arsenious anhydride was the addition of benzene or toluene; the vapours after condensation were freed from water by anhydrous copper sulphate and the dry hydrocarbon returned to the reaction flask. Sixteen arsenites were thus prepared, of which the physical properties are given.—**P. Vincensini**: Certain families of surfaces.—**Georges Darmois**: The deformation of space in the theory of relativity.—**Georges Calugaréano**: The exceptional values (as defined by Picard and by Nevanlinna) of meromorph functions.—**D. Wolkowitsch**: The problem of a solid movable about a fixed point.—**Salmon-Legagneur and Bertrand-Lepaute**: The synchronisation of circular balance wheels of chronometers. A method for synchronising escapements with circular balance wheels by alternating current from the mains.—**Jacques Valensi**: The utilisation of ventilating fans with adjustable vanes for regulating the air velocity in an Eiffel blower.—**Henri Mineur**: The residual velocities of the stars and the problem of the temperature of the Milky Way.—**Jacques Winter**: Remarks on the integral equation of Bloch (electronic theory of metals).—**R. Anthouard**: The characters of the supply currents of a discharge in air under low pressure.—**V. Posejpal**: A general formula for absorption.—**R. Freymann**: The effect of dilution and of temperature on the infra-red absorption bands. Molecular associations. It has been previously shown that when an alcohol is diluted with a solvent the intensity of the band due to the OH group increases, passes through a maximum, then decreases. It is now found that this is not due to electrolytic dissociation, and the hypothesis of molecular association is discussed.—**Servigne**: The carrying down of polonium by crystalline oxalates in nitric acid solution. The oxalates of lanthanum, scandium, calcium, and strontium have been examined from this point of view. The results of the experiments are in favour of the view that polonium is trivalent in its oxalate.—**Berthon**: The displacement of some chemical equilibria based on the selective adsorption of the hydroxides by silica gel.—**Jean Cournot and Jean Challansonnet**: The primary graphitisation of cast irons containing molybdenum. It is possible to add up to 2 per cent of molybdenum to grey cast iron without the formation of free carbides. The castings remain grey in spite of rapid cooling after pouring.—**Ernest Kahane**: The estimation of arsenic in organic materials after destruction with perchloric acid. Full details are given of the method, which is based on the use of a mixture of nitric, sulphuric, and perchloric acids.—**L. Debucquet and L. Velluz**: Organic compounds with the sulphides of tellurium, arsenic, and tin. The compounds described are of the type $TeS_2 . C_4H_{10}N_2 . H_2S$.—**André Duparque**: The petrographic characters of coking coals.—**J. P. Arend**: The original mixture of oolithic Lorraine-Luxemburg minerals.—**Raymond Furon**: The schisto-calcareous series of the Sudan: its base conglomerate and its stratigraphical position with respect to earlier series.—**N. Arabu**: The existence of phenomena of overlapping in the gneiss zone of Sainte-Marie-aux-Mines (Alsace).—**Louis Dangeard and Pierre Bout**: Observations on the constitution of the Perrier mountain, near Issoire (Puy-de-Dôme).—**L. Clariond**: The Stephanian of Ida ou Zal (western Morocco).—**Edouard Roch**: The interpretation of the stratigraphical series of the region of Entifa and Beni Ayatt (central Morocco) and a hypothesis concerning other Moroccan regions.—**Louis Dubertret**: The structural forms of Syria and Palestine; their origin.—**Edouard Salles**: The value of the electrical field of the atmosphere at high altitudes. Reasons are given for supposing that the figures of Andrée (of the order of 12 volts) are much too low.—**R. Bureau**: The rôle of the phenomena of propagation in records of atmospherics.—**A. Piccard, E. Stahel, and P. Kipfer**: The intensity of the cosmic radiation at 16,000 metres altitude. At this height there is a large increase in the cosmic radiation as measured by an ionisation chamber and by the Geiger-Müller counter.—**Ph. Joyet-Lavergne**: Some characters of cytoplasmic sexualisation in Algæ and Fungi.—**Fr. Rutishauser**: The chemical composition of *Vinca minor*.—**Louis Gallien**: The evolution of the generation descended from the neotenic forms of *Polystomum integerrimum*.—**A. Dehorne**: The morphological value of the blood corpuscles of *Magelona papillicornis*.—**René Wurmser and Mlle. Nelicia Mayer**: The equilibrium between lactic and pyruvic acids.

COPENHAGEN

Royal Danish Academy of Science and Letters, Feb. 6.—**Ojvind Winge**: A new species, *Brassica napocampestris*, originated through species crossing and chromosome doubling. On crossing *Brassica napus*, with 18 chromosomes, and *B. campestris*, with 10 chromosomes (haploid), Mr. H. N. Frandsen, Taastrup, Denmark, succeeded in getting a new constant species with 28 chromosomes haploid. The new type owes its origin to a somatic doubling in the F_1 zygote, in accordance with the hypothesis of 'indirect chromosome binding' (Winge, 1917).

March 4.—**Oluf Thomsen**: Experimental investigations on the transmissible leucosis in fowls.—**C. Wesenburg-Lund**: Danish freshwater cercariæ, parasitic on the blood. Danish forms have not been examined in detail for some time. Recent research has shown that there are at least forty species. Several are true plankton organisms. Furthermore, the family Schistosomatidæ is represented by the parasite responsible for bilharziasis. During the past year, research in North America, England, France, Germany, and Poland has disclosed species causing serious disease amongst aquatic birds and various skin diseases amongst bathers. Presumably the same organisms are responsible for these diseases in Denmark. Such diseases were previously explained entirely differently.

April 29.—**Niels Bohr**: The properties of the neutron. The remarkably small interaction between neutrons and electrons is a simple consequence of quantum mechanics.

WASHINGTON, D.C.

National Academy of Sciences (*Proc.*, 18, 28[illegible] April 15).—**Edward W. Berry**: The Mioc[illegible]

Idaho. Forty genera have been recognised, of which eighteen no longer exist in the north-western United States. Maples, oaks, beeches, and similar trees form the largest genera, giving evidence of well-distributed rainfall and mild conditions, which were presumably altered by post-Tertiary uplift of mountain ranges.—**Linus Pauling**: Interatomic distances in covalent molecules and resonance between two or more Lewis electronic structures.—**Matilda Moldenhauer Brooks**: The penetration of 1-naphthol-2-sulphonate indophenol, *o*-chloro phenol indophenol and *o*-cresol indophenol into species of *Valonia* from the South Seas. As with other species of *Valonia*, the first dye does not penetrate, and the other two enter in a colourless (reduced) form.—**James S. Potter** and **Maurice N. Richter**: Studies on mouse leukemia. (6) The predominating cell type in line 1. The chromosome number is forty, which is normal for somatic cells of the mouse, and none of the cytological methods used was able to differentiate these cells from similar cells in normal mouse tissue.—**R. J. Seeger**: A critique of recent quantum theories (2). A mathematical discussion directed towards the view that an incomplete interpretation of laws of physics would be preferable to the present principle of indeterminacy.—**Otto Beeck**: The ionisation of argon and neon by neutral argon beams. Argon ions formed by electron impact are accelerated and pass through argon gas, where they encounter atoms of argon and are neutralised; the neutral beam passes into an ionisation chamber containing argon or neon. In both cases, at 50-120 volts equivalent velocity of the neutral argon atoms, the intensity of ionisation produced is practically constant. The results indicate that ionisation by neutral beams is very efficient, and suggest that the neutral atom may play the rôle assigned to the positive ion in discharge through gases. —**F. Zwicky**: Ionisation in gases by ions and atoms. A theoretical discussion on which the experimental work of the preceding paper was based.—**William Duane**: (1) The mass of the electron. Using (*a*) Bragg's formula for reflection of X-rays by calcite, (*b*) Bohr's formula for the Rydberg constant, and (*c*) Einstein's quantum equation and the results of earlier X-ray reflection experiments, the rest mass (m_0) is found to be $9 \cdot 054 \times 10^{28}$; hence $e = 4 \cdot 773 \times 10^{-10}$ e.s.u. and $h = 6 \cdot 557 \times 10^{-27}$.—(2) An instrument for the photometering of the new X-ray lines. The negative of the spectrum is illuminated and a horizontal image of the lines to be examined is projected on to a horizontal slit before a photoelectric cell, through which there is a complete circuit including cell, battery, and galvanometer enclosed within metal boxes. The galvanometer deflexion is observed by a beam of light going to a horizontal slit behind which is a photographic plate. This plate and the photoelectric cell and slit are joined mechanically and move vertically. Thus a curve is traced out the points of which correspond directly to points on the negative of the spectrum under examination.—**Frederick G. Keyes** and **Samuel C. Collins**: The pressure variation of the heat function as a direct measure of the Van der Waals forces. A theoretical discussion and experimental observations. The gas is allowed to escape under a measured pressure through a platinum capillary to a lower pressure, while the capillary is heated electrically to maintain the system at a constant temperature. Experimental values for carbon dioxide and ammonia are in agreement with calculated values. The method is particularly suitable for low pressure and low temperature work.—**Eberhard Hopf**: Proof of Gibbs' hypothesis on the tendency toward statistical equilibrium.—**Hassler Whitney**: Regular families of curves (2).

CONTENTS

Science in Elementary Schools*

THERE has recently been published by the Board of Education a pamphlet summarising the information collected by a panel of H.M. Inspectors since early in 1930 regarding the teaching of science in certain types of post-primary schools, and offering suggestions for further improvement. This pamphlet is of more than usual importance, for the schools concerned are attempting, without the guidance of experience, what amounts to a revolution in educational practice; the aim of the 'Senior School' involving abandonment of the academic tradition in which its own teachers were themselves educated and trained.

Under the general title of 'Senior School' are included Selective Central Schools (308), Non-selective Central and Senior Schools (267), and Higher Tops, Durham (9), giving a total of 584 schools from which information was obtained, and of which about eighty were specially visited by selected inspectors. Of the 144,854 pupils in these schools, 132,199 were returned as taking a science course, the teaching being in the hands of 1391 teachers (913 men, 478 women). The figures make it clear that these new schools as a whole have decided that a course of work in science of some kind is desirable as a part of the normal curriculum for all children. This consensus of practice is a satisfactory sign; but inspection of the details shows that the problem of framing courses suitable for this type of school has not yet been solved, in spite of some praiseworthy efforts.

It must be borne in mind that the ages of the children at these schools generally range from 11+ to 14 years, and rarely to 16 years at the most; and that the great majority of the pupils never again attend any educational institution after they have left school. It is thus obvious that the aim of 'Senior Schools' should be to give a science course as complete as possible in itself as a preparation for ordinary life in the social rank to which the pupils belong; to attempt a course preparatory to more advanced study is a fatal mistake. That the schools have not yet realised this ideal is evident, for while the number of schools in which only one subject is taught is relatively small, no fewer than 264 schools make no provision for teaching biological subjects, and less than half teach both the physical and biological sciences. Boys' schools tend to limit their science teaching to chemistry and physics; and girls' schools, to a

* Educational Pamphlets, No. 89. Memorandum on the Teaching of Science in Senior Schools. (London: H.M. Stationery Office.) 1s. 3d.

less degree, to biology, usually botany; while in many mixed schools, where the happy mean might be expected, the boys take a course of physics, and the girls confine their attention to botany. Briefly, there is too much specialisation, and the outlook is thus narrow and lacking in contact with much of everyday life.

Blame for this unfortunate state of affairs is attributable to more causes than one; but undoubtedly the present condition of the external examinations for which candidates from these schools sit is largely responsible. It is true that the total number of candidates offering science is small—frequently in the single-figure region in any one school; but the examination syllabus inevitably influences, if it does not dominate, that of the whole school. In nearly all these examinations it is possible to present a single science subject; and, naturally enough, this tends to be the only subject studied in the school. Worse still, in physics it is possible to present only one branch; hence boys' schools exist in which the work is restricted to 'heat, light, and sound'.

Another potent factor contributing to the undesirable specialisation lies in the previous education and training of the teachers themselves. Analysis of the qualifications of 599 men teachers whose university records showed them to have attained a reasonable standard in science revealed that 547 have qualifications in physics, 510 in chemistry, but only 30 in botany and 8 in zoology. Among woman teachers the disproportion is less marked; here for every 100 qualifications in physical science there are 67 in biological. It is encouraging, however, to find that science teachers are availing themselves of short holiday courses in order to widen their knowledge and give greater breadth to their teaching.

To solve the problem confronting each of these schools no single cut-and-dried detailed syllabus is possible or desirable. Each school should adapt its science teaching to the special circumstances of its locality, that is, to those of the ordinary everyday life of the great majority of the pupils both during and after the school years. The surroundings and occupations of young men and women in a manufacturing town will be very different from those of persons dwelling in purely rural districts; and it is essential that the school science course should, for each category, be such that the after-school life shall be enriched with intelligent interest in the daily round of work, home life, and recreation.

There is, nevertheless, a certain amount common to the needs of all. Inasmuch as human beings are living creatures and subject to the same laws of life as other organisms, some knowledge of the fundamentals of biology and of the elements of human physiology and hygiene should be given in every school. Such universality would in a short time result in an instructed public opinion in matters of health, and thus in a more healthy, more serviceable, and happier community. Botany, so unreasonably favoured in girls' schools, cannot by itself achieve this. It ought not to be possible in any of the external examinations of these schools for a candidate to offer botany alone or zoology alone. The one subject, biology, embracing the essentials of both animal and plant life, should be compulsory, and should include a few life-histories in both kingdoms, especially of such organisms as are common and of economic or hygienic importance. Details of structure should be introduced and demonstrated only so far as they are needed to render intelligible the more obvious activities of living organisms.

Again, in this age of machinery, 'wireless', and other applications of the various forms of energy, no one, whether in country or in town, can live intelligently without some knowledge of the principles of the physical sciences. The teaching should start from the objects familiar to the child; say, the hot-water radiators or the electric lamps, and should work back to first principles. Interest is thus roused at the outset, and is sustained throughout the series of demonstration experiments designed to find out how the thing acts. In schools of this type, personal practical work by the pupils should not be allowed to occupy more than a small fraction of the time allotted to the science course. It is here that many teachers find it difficult to break away from the tradition in which they themselves were educated, failing to appreciate the great difference between their own past and the pupils' present needs for science. To start a course of physics, as so frequently, with practical mensuration, is a soul-destroying method. Calculation of areas, volumes, and the like is the work of the mathematician: time enough to determine any one of them when the information is actually required in the course of some scientific experiment.

Biology and physics, then, should form the main part of the science teaching in these schools. Chemistry has, of course, claims arising from its importance in industries and in agriculture; but in view of its intrinsic difficulty, of the short time available, and of the tender years of the children, it is recommended that in this subject the teaching

should go little beyond the simple chemistry of air and water, save in special local circumstances.

A further important point is that the several branches of science should not be taught as separate subjects. There are many links and points of contact between them; and teachers should be so trained in the theory and the experimental technique of each as to be able with confidence and success to combine physical and chemical experiments with their biological teaching and demonstrations.

Summing up, the science course in a 'Senior School' should aim at promoting an intelligent appreciation of man and his environment, and for this purpose a new method of approach is necessary. All who are responsible for such courses in Senior Schools should carefully consider the recommendations of this pamphlet; and those in charge at public schools, where the problem for the non-specialist is not widely different from that in 'Senior Schools', might also study it with advantage.

Concerning Mutton and Wool

(1) *Empire Marketing Board. Wool Quality: a Study of the Influence of various Contributory Factors, their Significance and the Technique of their Measurement.* By Dr. S. G. Barker. Pp. 328 + 41 plates. (London: H.M. Stationery Office, 1931.) 21*s*.

(2) *Growth and the Development of Mutton Qualities in the Sheep: a Survey of the Problems involved in Meat Production.* By John Hammond, with a Section in conjunction with A. B. Appleton. (Biological Monographs and Manuals.) Pp. xxvi + 597 + 53 plates. (Edinburgh and London: Oliver and Boyd, 1932.) 42*s*. net.

BIOLOGICAL products are commonly both complex and subject to variability. Research work on their production, whether genetic or nutritional, or even purely an attempt at classification, cannot proceed far before it becomes an urgent necessity to define the nature of the product and to measure its varying characteristics. More particularly is it necessary to consider those differences that are of practical importance.

It is significant that two volumes dealing with mutton and wool respectively should appear at the present time. Both are a response to the need for establishing a precise scientific basis for research upon sheep breeding and sheep nutrition.

(1) The two volumes are widely different in content. This is due to the very different development of knowledge in the two fields. Dr. Barker deals with a subject that has exercised the ingenuity of many workers for well over a century, a subject to which he has himself made important contributions. His book, therefore, is a review of the literature dealing with the wool fibre and its physical and chemical properties, together with related substances such as wool grease and common impurities. The book will undoubtedly prove of the utmost value to research workers in this field, for, until its appearance, there has been no adequate review in English. The literature is peculiarly scattered and many important papers are hidden in volumes that most students find difficult to obtain.

Dr. Barker covers the field with thoroughness, and appends a valuable bibliography. His purpose has clearly been to bring together the material and to give the reader a clear account of the scope and findings of each paper. It is not a critical review and usually each author's conclusions are set forth without much comment. It is more useful to the research worker, however, that the volume should be comprehensive rather than critical.

The book is admirably produced and illustrated and contains numerous tables. The bibliography is made to serve as an authors' index, but there is no subject index. This is an unfortunate omission in a book that will undoubtedly take its place as a very valuable work of reference.

(2) Mr. Hammond's book is the record of nearly twenty years of research. Most workers on animal nutrition have been content to consider only gross weight and chemical composition, and while it is true that much valuable information can be secured in this way, there are many qualitative and quantitative differences that cannot be expressed in these terms. Mr. Hammond states in his preface that he has attempted to approach the problem from the other end by making observations on the product and then working backwards to discover the factors that affect its formation. This novel approach has yielded results of outstanding interest, and Mr. Hammond's observations, fully and clearly set forth in this book, will prove a mine of information to research workers concerned with any aspect of meat production, and will also prove an inspiration to all who are confronted by similar problems in other fields.

In reviewing a book of this size, which contains a mass of detailed tabular information of such an original nature, it is only possible to indicate the scope of the work and to mention in passing one or two of the host of interesting points that are raised.

The book is divided into five parts. The first deals with the rate of growth in live weight

flock of Suffolk sheep. Variations are related to a number of factors such as age, sex, number of young, time of lambing, and so forth. In the second part the argument is carried a stage further. Carcase percentage is considered, again in relation to the factors that affect it. This section also includes data on the relative development of organs, and it is clearly shown that each organ follows a growth curve of its own. Breed differences are striking, and Mr. Hammond makes the interesting suggestion that when the size of a species is reduced, the body decreases more rapidly than the head, and that when a species is increased in size, the body increases more rapidly then the head. This is probably due to the fact that the head reaches its maximum rate of growth early. The third part is a very complete account of variations in the rate of development of different parts of the skeleton, that is, of the basis of bodily conformation. Early maturity is regarded in general as a desirable feature in a meat-producing breed, but Mr. Hammond suggests that this is a more fundamental and inevitable trend than the practical man has perhaps realised, for it is pointed out that the most perfect meat conformation will be found in the type that matures early. "Early maturity and ultimate breed improvement go hand in hand."

The fourth part deals with variation in the proportion of muscle, fat, and bone in the carcase, and includes general observations on the composition of the gain made at different ages and the economic considerations affecting age of slaughter. Mr. Hammond suggests that in the early maturing breeds the point has been reached at which the relatively low rate of reproduction of the sheep is becoming a serious limiting factor. He is doubtful whether the sheep can hold its own in intensive farming unless improvement can be effected in this direction.

The fifth part of the book is written jointly with Dr. A. B. Appleton and is entitled "Study of the Leg of Mutton". It is a minute analysis of the anatomical (and chemical) differences that determine economic value. The section that deals with the histology of muscle is of particular interest and importance. The histological differences are surprisingly large and definite, and are undoubtedly closely associated with variations that determine the edibility of meat.

The last section of the book deals with two factors that affect edibility, namely, tenderness and flavour. Seldom can the cooking of legs of mutton in the kitchens of a Cambridge college have been supervised with such anxious care as on the [illegible] when Mr. Hammond entertained his friends at remarkable feasts! The individual muscles were dissected out, and the guests, all men used to scientific investigation, were asked to place the muscles in order as regards tenderness and flavour. The two characteristics vary independently; for example, the biceps femoris heads the list for tenderness, but is lowest for flavour except for the psoas major. The semimembranosus heads the list for flavour, but occupies a lowly position for tenderness. The correlation between tenderness and small size of muscle fibre is 0·71, and between tenderness and 'fineness of grain' 0·33, whereas the correlation of this characteristic with paleness of colour and amount of marbling (in any one animal) are only 0·20 and 0·11 respectively. The correlation between high flavour and dark colour is 0·45, and between high flavour and coarse grain 0·48, while there is no correlation with fibre size or with amount of marbling. So the book ends with the clear indication that even the most elusive characteristics of a variable product can be related to what can be weighed and measured.

There are full indexes of authors and subjects and a copious bibliography, though one may regret that the usual biological practice has not been followed, in that titles of papers are omitted. The illustrations are admirable and the tables very clearly arranged. The whole arrangement and production of the volume are delightful and reflect the greatest credit on the editors of the series and on the publishers. J. A. FRASER ROBERTS.

Diatoms

Kryptogamen-Flora von Deutschland, Österreich und der Schweiz. Von Dr. L. Rabenhorst. Zweite vollständig neu bearbeitete Auflage. Band 7: *Die Kieselalgen Deutschlands, Österreichs und der Schweiz mit Berücksichtigung der übrigen Länder Europas sowie der angrenzenden Meeresgebiete.* Von Dr. Friedrich Hustedt. Teil 1. Pp. xii + 920. 63 gold marks. Band 9: *Die Flechten (Lichenes) Deutschlands, Österreichs und der Schweiz mit teilweiser Berücksichtigung der übrigen Länder Europas.* Herausgegeben von Dr. Alexander Zahlbruckner. Abteilung 4: *Cladoniaceen und Umbilicariaceen.* Hälfte 2: *Die Gattung Cladonia.* Von Dr. Heinrich Sandstede. Lief. 1, 2. Pp. 531 + 34 Tafeln. 47·50 gold marks. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1930–1931.)

SINCE the publication of Van Heurck's synopsis and Peragallo's treatise on the marine diatoms of France, no comprehensive systematic treatment

of these difficult forms has appeared, for Schmidt's "Atlas der Diatomaceenkunde", most valuable as a work of reference, scarcely fulfils these functions. While the contributions of Meister, Boyer, and especially the new edition of Bacillariales in the "Süsswasserflora" by Hustedt, each serve a useful purpose in their respective fields, a treatment covering the majority of known forms has long been needed. Fortunately, it has fallen to the lot of Hustedt to undertake this work, and the volume now under review amply testifies to the thoroughness with which he is carrying out his task. It comprises introductory matter occupying some two hundred pages, as well as the taxonomic treatment of the centric forms.

The former deals with the structure, life-history, and physiology of diatoms, as well as with the technique involved in their preparation and study. In a taxonomic work most room is naturally given to a consideration of features of major systematic importance, and considerable space is devoted to a discussion of the structure of the cellular envelope. It is unfortunate that details of the author's recent work on the raphe of Epithemioideæ, Nitzschioideæ, and Surirelloideæ could not be included, and one may express the hope that they will find a place in later sections. Some sections (for example, that dealing with chromatophores) would have gained by the mention of more abundant examples. The citation of literature is not always satisfactory; thus, one seeks in vain in the respective bibliographies for the references to Heinzerling and Richter cited in the third and fourth sections, although they are mentioned elsewhere. More particulars as to the occurrence and general biology of diatoms would have been useful; their periodicity is barely mentioned, and there is no reference to Pearsall's work. With most of the views expressed in the introduction one will be in general agreement, but the statement on p. 9 as to the haploid nature of centric diatoms and the occurrence of reduction during germination of the zygote, never very probable, is scarcely in accordance with recent work. As a whole, however, the introduction constitutes a useful summary of present knowledge.

The taxonomic section dealing with Centricæ, the classification of which broadly follows Schütt's system, merits unstinted praise. The keys are well constructed, but in the larger genera the species might usefully have been numbered, so as to facilitate the finding of them in the descriptive part. The numerous difficult forms are illustrated by excellent text-figures, many original and quite as clear as the figures usually furnished on plates. The concise diagnoses are often accompanied by critical remarks, adding greatly to the usefulness of the work, which has clearly been prepared with care by one who is a master of his subject.

Sanstede's monograph of the genus *Cladonia* is a work that will be highly valuable to the specialist. The species are grouped in the three subgenera *Cladina*, *Pycnothelia*, and *Cenomyce*, and are illustrated on a considerable number of plates. A particularly useful feature is the clear distinction of different habitat-forms.

F. E. FRITSCH.

Modern Physical Chemistry

(1) *Physical Chemistry: an Elementary Text, Primarily for Biological and Pre-medical Students.* By Prof. L. J. Gillespie. (International Chemical Series.) Pp. ix + 287. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1931.) 16*s.* 6*d.* net.

(2) *Outlines of Theoretical Chemistry.* By Dr. F. H. Getman. Fifth edition, revised and largely rewritten by Prof. F. Daniels. Pp. ix + 643. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1931.) 22*s.* 3*d.* net.

(3) *Industrial Chemical Calculations: the Application of Physico-Chemical Principles and Data to Problems of Industry.* By Prof. O. A. Hougen and Prof. K. M. Watson. Pp. vii + 502. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1931.) 28*s.* net.

(4) *The Kinetics of Homogeneous Gas Reactions.* By Dr. L. S. Kassel. (American Chemical Society Monograph Series, No. 57.) Pp. 330. (New York: The Chemical Catalog Co., Inc., 1932.) 6.50 dollars.

(1) PROF. GILLESPIE'S book is a courageous attempt to bring the modern conceptions of physical chemistry within the range of comprehension of what he calls "biological and premedical students". If by the latter we understand students preparing for first medical examination in Great Britain, then the book will be found too difficult. For slightly more advanced students of physical chemistry, whether medical or not, it will be found both stimulating and helpful. The emphasis throughout is on biological problems, in which physical chemistry is recognised as perhaps the most important guiding principle, and the range of subjects selected is admirable for this field. More attention might, it is true, usefully have been given to questions of reaction velocity and catalysis, the chapter on these subjects being somewhat adequate and out of proportion as com-

the rest of the book. After all, there could be no life if everything were in equilibrium or pseudo-equilibrium.

In many cases deductions of formulæ are given, in some cases by simple and ingenious methods, and this part of the book is well worth study by teachers and students of general physical chemistry. The thermodynamic treatment is the most prominent, the so-called free energy being introduced and used in a very interesting and instructive way. The perplexing question of the signs of electrodes and cells is fully dealt with, the author adopting one of the American conventions in the first part of the book, and the other in the second part (pp. 133, 245). The activity conception is clearly explained and is used throughout, and there is a good chapter on the Donnan equilibrium.

This book is a very good elementary account of certain selected aspects of physical chemistry, and is certain to prove useful both to teachers and students.

(2) Prof. Getman's textbook, first published in 1913, represents, as it were, the extrapolation of the classical type of treatise initiated by Ostwald's "Outlines of General Chemistry" into the modern period. The fact that it is now in its fifth edition shows that it is a highly successful and valuable work, and in its modern form it reflects faithfully the important outlines of the science. Prof. Daniels had a good stock on which to graft the new ideas, and he has performed his duty admirably, the whole organism now being as one.

A very praiseworthy feature is the inclusion of descriptions of experimental methods, which have tended to disappear from some books, leaving the incorrect impression that physical chemistry is a branch of mathematics. The sections of electrochemistry are particularly good, careful attention being given to all points which usually cause difficulty; and the introduction of activities, with good examples of their application, makes this part of the book a real help to teachers and students. The chapter on thermodynamics gives a good summary of the American system of calculations. Many problems are given, and answers to some are provided.

A few minor points of criticism may be mentioned for consideration by the authors when a new edition is in preparation. In considering viscosity, the question of turbulent flow might be mentioned; the so-called 'factors' of energy are introduced (p. 111), but those of thermal energy are surely temperature and entropy, not temperature and heat; and in any event it is not true to say that "all forms of energy may be expressed as the product of two factors", since radiation cannot be so expressed; the derivation of the Gibbs-Helmholtz equation on p. 133 is not clear, although it follows the usual lines, since the student does not see that equation 67 refers to a cycle and equation 69 to an isothermal process; the "approximate form" of Maxwell's distribution law, considering distribution in two dimensions only, although it "may be sufficiently accurate for most work in chemical kinetics", cannot represent the facts, and its use in other fields has led to mistakes; on p. 474 it would perhaps have been better to have given the deduction of the formula for the antimony electrode rather than for a hypothetical case.

(3) Chemical engineering is a branch of applied physical chemistry, as the authors of "Industrial Chemical Calculations" recognise by their sub-title. The change-over from the lecture room and laboratory to the engineer's office and the works is partly a matter of arithmetic, and very few additional ideas or conceptions are involved. The physical chemistry, however, must go somewhat beyond what the student usually learns in a degree course, and it must be brought into intimate relation with practice.

Such a book as the present one will go a long way in helping the student to bridge over the transition period, and it should be valuable to men going into industry. As the authors say, the method of tackling a calculation needs careful consideration. Most students, in working out a gas volume problem in which Fahrenheit temperatures are involved, would first convert these to centigrade and then proceed on the old familiar lines, with needless loss of time and energy. On the other hand, the use of short cuts is often dangerous, and, as the authors say, results only in the saving of time for the calculator who is experienced and proficient. "In industrial practice it is necessary not only to obtain a solution rapidly, but also to present this solution in such form that its correctness is certain." There are well-tried ways of doing this, and they are explained in the book.

Many problems are worked out in the text and several are given for solution. It would have been very much better to have given answers to these, since, unless the student has always a teacher to fall back upon who is willing to work out these problems, he does not know whether he is making progress or not. The authors provide good tables of constants and data, and give references to literature.

The section on fractional distillation, in view of the great importance of the subject, is perhaps a

little inadequate and should be extended in future editions. The book is one which can be recommended as likely to prove very valuable to students and teachers. It is well written, and the authors have spared no pains in making their presentation of the subject both intelligible and authoritative.

(4) The treatment adopted in Dr. Kassel's interesting and useful book is essentially that of statistical mechanics, which he considers has been the most successful in this field, and of which he gives a condensed but clear account in the opening chapters. The theoretical treatment and the detailed consideration of the experimental data are separated, which makes for clearness, the theory being discussed in the first part of the book and the data in the second, larger, part.

This second part of the book is particularly helpful, since the author has examined the data with great care, involving the recalculation of much experimental material and, incidentally, the revelation of no insignificant number of arithmetical errors in the original papers. The theoretical treatment includes a good critical discussion of the wave mechanical method, of intermolecular forces in imperfect gases and their influence on collision frequencies, and on various types of reaction. This part is clear and sufficiently advanced to be of real utility. After a chapter on experimental methods, the discussion of particular reactions is begun, and the field is very satisfactorily covered.

There is a useful appendix giving numerical values of heats of dissociation. Dr. Kassel's book may be recommended as giving a clear and authoritative account of a field of investigation which has attracted a considerable amount of attention in recent years.

J. R. Partington.

Short Reviews

Firedamp Explosions and their Prevention. By W. Payman and Prof. I. C. F. Statham. Pp. xii + 158. (London: Oxford University Press, 1931.) 12s. 6d. net.

The steady decline in loss of life arising from firedamp explosions in coal mines of itself bears testimony to the precautionary measures which have been developed to minimise this ever-present danger. The authors have embodied in short compass an account, drawn largely from papers published during recent years by the Safety in Mines Research Board, of the properties of firedamp, its possible means of ignition in a mine, and how, by the construction, maintenance, and testing of apparatus used in coal mines, the hazard of explosion may be minimised.

In outlining the statutory requirements for safety lamps, bells, relays, telephones and shot-firing apparatus, details are given of the tests undertaken at the research stations at Buxton and Sheffield. It is of interest to note that more stringent requirements as to the candle power of safety lamps are indicated, for it is held in many quarters that better lighting would prove a most valuable contribution to increased safety. A large section of the book deals also with the design and testing of flame-proof electrical apparatus, the use of which is rapidly increasing. Thus, between 1912 and 1929, the horse power of electrical plant installed in British mines increased by an average of 35,400 a year; without the aid of electrical energy many of our mines could not produce coal to-day at an economic price. The final chapters are devoted to coal-mining explosives and their substitutes, the nature of the flames produced by explosives being well illustrated by photographic records. On all these matters comparison is made with United States and Continental practice.

The book is written authoritatively, is free from typographical errors and well produced, and should be in the hands of all associated with mine management. Being mainly a compilation of statutory tests, etc., it suffers somewhat from 'cataloguing' and would have made better reading had more space been devoted to the historical side. It seems unbelievable that a book on firedamp explosions could have been written without mention of Sir Humphry Davy.

Two Thousand Years of Science: the Wonders of Nature and their Discoverers. By Prof. R. J. Harvey-Gibson. Second edition, revised and enlarged by Dr. A. W. Titherley. Pp. x + 508. (London: A. and C. Black, Ltd., 1931.) 12s. 6d. net.

The fact that a second edition of this book has been called for only a year after the publication of the first is sufficient testimony to its general appeal. In its present form it includes much more information relating to the modern period, while the provision of chronological tables aids the reader to arrive at a true perspective. Dr. Titherley has clearly been at pains to check his facts—no light task in a survey of two thousand years—and though some of the judgments expressed are perhaps a little superficial, the book as a whole forms a reliable and readable guide to the principal course of the development of science.

Such 'popular' accounts of the work of men of science serve a very useful purpose in the modern world, and the pity is that there are so few of them. Admitted that a great deal of present-day scientific theory is beyond the comprehension of the layman, it yet remains true that most of the results, and many of the methods, can be rendered intelligible by skilful exponents; and that the public is eager for such fare is sufficiently obvious from the excellent reception accorded to simple explanations of scientific achievement when authoritatively written. We hope that the example of the present book may be widely followed: meanwhile, in the interests of accuracy, we may perhaps direct attention to a few minor errors that have eluded Dr. T

vigilance. Basil Valentine—if he ever existed—certainly did not publish the "Triumphal Chariot of Antimony" about 1430; the discovery of carbon dioxide is generally attributed to J. B. van Helmont, not to his son Mercurius; the Saracens are probably wrongly blamed for burning the library at Alexandria; Mayow's "spiritus nitro-aereus" is not equivalent to the modern oxygen; and the "Summa perfectionis" is scarcely the oldest chemical book.

Simple Determinative Mineralogy. By H. R. Beringer. Pp. vii + 239. (London: Mining Publications, Ltd., 1931.) 10*s*. 6*d*.

THIS is definitely not a textbook of systematic mineralogy, but a handbook intended to assist students and prospectors in the field determination of mineral species.

The method adopted is based on the recognition of two physical characteristics generally easily and quickly determinable—specific gravity and hardness. Accurate determination of these two properties should serve to restrict any mineral to a more or less small group. Further recourse may then be had to the blowpipe and to the description of the other properties of suspected species.

Practical methods for the determination of specific gravity are dealt with in the first part of the book. Two mineral lists make up the bulk of the text. In one the species are grouped according to specific gravity, the members of each group being listed in order of hardness. In the other the minerals are arranged solely in the order of their specific gravity, and a concise account of their other physical properties is given for each species. Notes are added on their chemical properties. There is also a list of the elements, with a short account of their blowpipe and other chemical reactions.

The author has had many years' experience as a teacher of practical mineralogy in the School of Mines at Camborne, and his method has been in use there for more than ten years. This should be sufficient recommendation of the practical utility of his book.

Key to and Primer of Interlingua: or Latin without Inflections meant to be used as an International Auxiliary Language amongst Peoples of various Mother Tongues. Pp. v + 168. (London: Kegan Paul and Co., Ltd.; New York: E. P. Dutton and Co., 1931.) 4*s*. 6*d*. net.

THIS excellent little book shows the degree of perfection and range of application of the auxiliary language invented by Prof. G. Peano and his friends. Interlingua, or Latin without inflections, is meant to be used as an international auxiliary language amongst peoples of various mother tongues. Yet in reading through the rules of Interlingua, the glossary, and the interesting reading book, one is bound to find that, if this auxiliary language might satisfy the requirements of Latin races, the Anglo-Saxon languages, and the Slav languages, not to mention the extra-European languages, can scarcely look upon it as a helpful [illegible]. On the other hand, scholars would always prefer Latin to the Interlingua owing to the history and the documents which enshrine it. Further, a language which is spoken with difficulty by a band of enthusiasts and has no literature of its own can scarcely appeal either to the pragmatist or to the lover of artistic productions. The admiration one cannot help feeling for the untiring and disinterested efforts of Prof. Peano's school will never outbalance the deadweight of the irreparable curse of the Tower of Babel. T. G.

East Yorkshire: a Study in Agricultural Geography. By Dr. S. E. J. Best. Pp. xv + 189 + 8 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1930.) 16*s*. net.

DR. BEST'S book is typical of the surveys which modern students of geography are making for different areas in Great Britain, and shows how closely geography and agriculture are allied. The method is to survey the country from the various geographical points of view, studying its formation, topography, climatic and other factors, and then to set out the agricultural statistics in map form and discuss the agricultural utilisation of the land in the light of its geographical and topographical features. This book is an admirable example of the aid which agriculture and geography can mutually render.

In a future edition it would be helpful if the author would give an index and a bibliography. The literature of the subject is widely scattered and often diffuse; students would be greatly assisted if a list of the best authorities could be presented to them. The author pays a tribute to the work of his distinguished namesake, Henry Best, who in the seventeenth century published an account of farming in Yorkshire; this book was reprinted by the Surtees Society but has long been unobtainable by students: one cannot help wishing that a reprint were available.

The Birds of Tropical West Africa; with Special Reference to those of the Gambia, Sierra Leone, the Gold Coast and Nigeria. By D. A. Bannerman. Published under the Authority of the Secretary of State for the Colonies. Vol. 2. Pp. xxix + 428 + 15 plates. (London: The Crown Agents for the Colonies, 1931.) 22*s*. 6*d*.

THE first volume of Mr. Bannerman's work has already been highly commended in these pages, and the second deserves equal praise. The book admirably combines the two purposes of giving a summary of knowledge of West African birds and of providing a working guide to observers on the spot. This volume has also particular interest for European ornithologists, as it deals with the occurrence and habits of many northern species that are known in Africa as migrants. It has already been remarked that publication of the work is supported by the governments of the British territories in West Africa: further aid from the Gold Coast has now made it possible to increase the number of illustrations as compared with the first volume. These include some beautiful coloured plates and many drawings of excellent clearness.

Scientific Research and Industrial Development *

SO far we have discussed only one aspect of the contribution of science to industry. Equally important is the contribution which science makes in technique, the provision of new technical methods. The importance of this aspect of the service of science to industry was enforced on British industry in the early days of the War, when our dependence on Continental firms for all classes of scientific instruments and glassware imposed a considerable handicap in the expansion of the munitions and other industries to meet the war-time demand. Without the instruments of precision for measurement and control of temperature, pressure, refractivity, and other properties, which have been evolved by purely scientific work, industrial development would have been much more laborious. Modern advances in the measurement of high temperatures paved the way for the developments in the metallurgical industries. The development of the newer industries, such as the radio industry, the manufacture of synthetic resins and rayon, is essentially a record of advance closely related to the utilisation not merely of scientific discoveries but also of scientific methods and scientific instruments for purposes of control.

The significance of such methods as X-ray analysis, ultra-violet light, hydrogen ion determination, thermionic valves for control purposes, including automatic control, in industry is only now being appreciated. In high-pressure reactions as well as low-pressure reactions and distillation in very high vacuum, science has provided industry with a whole range of new technique. Scientific work on the two forms of hydrogen has recently simplified the evaluation of industrial catalysts, while almost simultaneously the discovery of the selective properties of a copper chromite catalyst has enormously increased the possibilities of development in the industrial hydrogenation processes.

X-ray methods themselves provide a striking example of the reaction on industry of scientific technique. The recent application of X-ray methods to textile research has led to discoveries relating to the structure of cellulose, wool, and hair which throw new light on just those typical properties of wool which are of fundamental importance in manufacturing operations. As a result, a correct interpretation of the conditioning, dyeing, and other adsorptive processes has been facilitated and a method elaborated for measuring the surface scale structure of the wool fibre which represents the first step towards placing the important technical operations of milling on a scientific foundation. In addition, the discoveries lead to an interpretation of the structure of cellulose which has a direct bearing on the mercerisation process.

Refinements of technique are not the only factor that is continually changing the relations of science and industry and determining the rise of new industries or decay of others. Almost every year sees fresh compounds, formerly curiosities and accessible only by tedious and costly laboratory processes, produced on the commercial scale at a price which allows their use in industry or in scientific laboratories as the raw material of further researches. The papers published in the journal of any chemical society reveal the way in which the scope of scientific research has been enlarged and influenced by industrial advances. The utilisation of waste materials, the delicate balance between by-product and main product, the fall or rise in price of basic materials like sulphuric acid, methyl alcohol, glycerol, which alone may result in new routes to existing products—the war-time shortage of sulphuric acid, for example, led to the development of alternative methods for phenols and amines which have not been entirely replaced by the earlier methods—these are factors which continually emphasise the dynamic character of industrial research and frequently have far-reaching effects on scientific research.

While science has thus provided industry with instruments of precision and methods of attack on technical problems, an important contribution has also been made in the field of industrial health and safety. Until science had revealed the cause of yellow fever and the methods of its prevention and control, the resources of the engineer were inadequate to construct the Panama canal. Merely to walk through a modern dry battery or accumulator factory is to realise how medical science, by examining the causes of industrial poisoning, dusts, and their prevention, has revolutionised conditions of work. Hundreds of industrial processes operate smoothly every day because the scientific study of the properties of materials has enabled working conditions to be devised which satisfy stringent requirements of safety and efficiency. Industrial health is, however, not simply a matter of securing that adequate precautions are taken in the handling of toxic materials or operating dangerous machinery. Science can do much to eliminate such risks, and the accident rate in works where inflammable, explosive, or highly toxic substances are handled under pressures of hundreds of atmospheres or at very high temperatures is frequently below the average in industry.

In addition, although science cannot altogether eliminate the human factor, which is responsible for ninety per cent of industrial accidents, accidents are, however, always unduly prevalent among a comparatively small number of workers. The evidence shows that absenteeism due to sickness is usually abnormally high among the same persons, and that on an average they are also less skilled at their work. Generally it may be said that those who are most suited to their work or environment react the most healthily to their environment, whether we measure the reaction by working efficiency or skill, tendency to sickness, or proneness to accidents.

It is thus evident that vocational selection is of outstanding importance as much from the point of view of industrial safety as from that of in-

* Continued from p. 265.

efficiency. No more valuable work is being done by the National Institute of Industrial Psychology than that which the Institute is carrying out in this field, and as a result of the application of scientific methods remarkable progress has already been made. In spite of the cramping influence of unemployment on the application of some of the newer methods of vocational selection and guidance which have been elaborated, it has been demonstrated that we can at any rate avoid placing in dangerous positions those peculiarly liable to accidents, and the policy of eliminating the unfit before and not as a sequence to accidents is not utopian. A classification into risk classes according to personal characteristics has already been indicated as possible.

The part played by science in securing improved and safer conditions of labour is often overlooked, but the work of the Industrial Health Research Board alone would demonstrate the importance of scientific research in this field. Industrial physiology, of course, is only one section of the field of scientific management, but it is the section in which the most important modern developments have occurred. During recent years the study of industrial physiology and psychology has elaborated methods of preventing strikes and of promoting co-operation between the different organisations of production which are to-day part of the scientific organisation of labour in America. These researches have the same object as the strict application of Taylor's principles in factory and workshops. The success of such work is demonstrated by the changed attitude of the workers, who recognise that attempts made to increase production have become more humane and devote more attention to the human side and the health of the operators.

Much of the work of the Industrial Health Research Board is only preparatory, but conclusions have already been reached which involve no revolutionary changes, and, indeed, only place on a scientific and statistical basis the empirical practices of progressive firms. The value of such results is demonstrated by the fact that they have already been adopted in certain branches of industry, and more widespread acceptance would greatly increase their utility. Scientific research in industrial physiology and psychology is continually improving conditions of work so that both the health and efficiency of the worker are improved, and it is now being applied to ensure that, so far as possible, young persons entering industry are fitted into occupations for which they are temperamentally suited.

It is against this background that we have to place the constructive plans of science for our social and industrial future, but the present economic position of the world has led to certain questionings as to the part which science has to play in the future. Leaders like Sir Harry McGowan have perceived that scientific and technical progress have far-reaching reactions not only on industry but also on the finance and economics of the whole State. [illegible]tific discoveries and their application in in[illegible] dislocated the major balance between industrial and agricultural production, and have threatened the whole social, financial, and political structure of our civilisation. Sir Harry McGowan uttered no idle warning when he hinted at the possibility of our common civilisation perishing through our inability to control the forces which applied science primarily has created. Under the influence of science, not only industry but also accepted views of trade and competition are changing their value, and policies such as free trade and protection acquire a new significance.

Sir Harry McGowan has urged that the policy of industrial co-operation which has developed notably in chemical industry under such forces should be extended into the more difficult field of international co-operation—as indeed has already been done in some few branches of industry, though with what success it is difficult as yet to say. As an aid to such control or development, Sir Harry McGowan visualises a Minister of State devoted to the task of promoting the co-ordinated reorganisation of all our industries, and beyond this an international chemical council to provide chemical industry with a world-wide range. The effective rationalisation thus secured would stabilise development and co-ordinate or expedite research.

There is, however, even now much confusion between rationalisation and the processes of mere amalgamation or cartel which involve no scientific planning or management, and this confusion tends to retard progress. In addition it has to be admitted that in spite of the contribution to industrial progress which science has made during the last century, there are still many sections of industry where scientific research has yet to be recognised as one of the principal avenues of progress. Of this fact the annual reports of the Department of Scientific and Industrial Research provide plentiful evidence, and it will be sufficient to refer to the poor response of the shipping and shipbuilding industries to the offer of the Department to provide half the cost, up to £10,000, of erecting a second William Froude Tank at the National Physical Laboratory for research in connexion with ship resistance and propulsion and tests on ship forms, propellers, etc. In consequence of the congestion of work in the existing tank, not only was research being hindered, but also orders for testing were accumulating to such an extent that they were frequently withdrawn and sent to the Continent, where in recent years similar facilities have greatly increased. It is obvious that if the testing of ship designs is better carried out abroad, orders for construction are likely to follow them abroad. By its failure to respond to this offer the shipping industry clearly was committing suicide, and had not the Advisory Council, in view of the vital importance of this industry to the nation, revised its recommendation and suggested that the whole capital cost of a new tank should be provided initially by the State, the depression in the shipping and shipbuilding industries must inevitably have increased to a point from which any recovery of competition with Continental rivals would have been impossible.

If, however, there are important sections of industry which have still to learn that, while scientific research cannot provide a ready-made solution of our present industrial difficulties, it does point the road along which persevering effort may enable industry to find a way out of those difficulties, it is important to remember that there are accordingly industries the difficulties of which are due less to economic conditions than to neglect of scientific method and research in the past. This is essentially the mark of defective leadership. Such industries are unlikely of themselves to evolve any constructive plans on broad enough lines to serve the national and not merely individual interests and to eliminate the more wasteful forms of competition and overlapping. The scientific planning, which Capt. Macmillan and his followers see as a logical necessity under a tariff policy, cannot be expected of them, and there is, on the contrary, the danger that protection will be used by industries of this type to bolster up the inefficiency of the past. There is every reason to insist that protection should only be afforded to these industries on the understanding that they definitely put their house in order and re-orientate their attitude to fundamental research. They must undertake to carry out investigations designed to yield a reserve of fundamental knowledge which can equally assist in tiding over bad times and in strengthening the industry to meet independently competition from abroad.

The Electrification of British Railways

THE International Electrical Congress was opened at the Sorbonne, Paris, on July 5. More than a thousand delegates representing thirty-one countries attended it. There were several papers on electric railway engineering, most of which discussed the history of electric traction and the modern practice of using direct current at 3000 volts on the railway side of the substations. A paper by Sir Philip Dawson discussed the electrification of British railways.

Sir Philip pointed out that two factors have notably influenced the development of electric traction on British railways. The first and most important was the grouping of numerous small railways into four large companies which took place shortly after the War. The Southern Railway serves the south-east and south-west of England, the track being equivalent to 4000 miles of single-line railway. This figure does not include the lengths required for sidings and for garaging railway carriages. The Great Western Railway serves Wales and the west of England, and if we neglect a few small Welsh railways, was practically unchanged by the grouping. The equivalent track length is about 6550 miles. The London, Midland and Scottish Railway serves the west side of the country from London to the north, the equivalent itinerary of track being 13,600 miles. The London and North Eastern Railway serves the north-east of England and Scotland, the equivalent length of the track being 7100 miles.

Many of the companies which were absorbed by these groups were pioneers of electrification and were eager to extend the electrified portions of their lines. So far back as 1904 the Lancashire and Yorkshire Co. electrified the lines between Liverpool and Southport, and just before the War so also were many lines around Manchester. In 1904 the North Eastern Railway Co. had electrified the suburban lines around Newcastle. The London, Brighton and South Coast Railway had very ambitious schemes for electrifying its lines, and the South Eastern and Chatham Railway had actually passed the contracts for electrifying all its suburban services. In several cases the 'grouping' greatly altered the policy of the original companies.

On railway lines where the traffic is heavy or where the gradients are steep, electrification has many advantages. In industrial districts where the density of the population is great, electric railways are particularly useful. These regions generally follow coal seams. In Scotland, for example, there is one from the east to the west between the Clyde and the Forth. To electrify the line between Glasgow and Edinburgh would be a very promising project. In the north of England there are many large coal mines extending through Durham to Cumberland, the coal area covering a space about fifty miles long and twenty miles broad. There are isolated coal mines in other districts, and there is a coal district in South Wales having a length from east to west of about seventeen miles and a breadth of about twenty miles. Leaving the towns out of account, the density of the population varies between 500 to 1000 inhabitants per square mile. No region of the world can compare with Greater London, which within an area of about 460 square miles contains a population of 12 million inhabitants—a population which is greater than a quarter of the total population of Great Britain, more than half that of Belgium, and equal to three times that of Switzerland.

The Southern Railway has little mineral traffic. It serves all the country south of the Thames and depends largely on its local traffic. The Great Western Railway has important mineral and goods traffic. It serves the south of Wales and the tin mines of Cornwall. The London, Midland and Scottish Railway serves Scotland and the Midlands of Lancashire and Yorkshire. It serves the important ports of Liverpool and Glasgow. The London and North Eastern Railway traverses the great industrial regions in the north of England and in Scotland. In these four railways the receipts from the mineral and merchandise traffic are 25, 57, 59, and 64 per cent of the total traffic receipts respectively.

The other important factor affecting the use of electric traction in railways was brought into existence when the Act of Parliament of 1926 created the Central Electricity Board to control the production 'in bulk' of the electricity generated

Britain. The grid now practically joins up all the 'effective' generating stations. The overhead lines are roughly parallel to many of the main railways.

The Southern Railway inherited from the London, Brighton and South Coast Railway a very flourishing suburban electrified system. Had not the grouping altered matters, it was the intention of the directors not only to finish the electrification of all their suburban systems, but also to work electrically the whole of the main lines as far as Worthing, Brighton, Eastbourne, and Hastings. Taking into account the fact that most of the lines were actuated by direct current, the Southern Railway adopted the d.c. system as the standard. It is still engaged in electrifying the passenger lines from London to Brighton and Worthing on this system. Its electrical lines at present are equivalent to about 750 miles of single track, besides the mileage required for side tracks, garaging purposes, etc. It possesses no electric locomotives, using 881 electrified motor carriages. Only a few miles of the Great Western Railway are electrified. The London, Midland and Scottish Railway has electrified the lines between Liverpool and Southport, Lancaster and Morecambe Bay, and Old Broad Street to Watford. The London and North Eastern Railway has only electrified a suburban section at Newcastle and a goods line in the neighbourhood of Sunderland, from Newport to Shildon. On the Newport line, electric locomotives are used. There are also several lines of purely local interest such as the Underground Railways of London.

The Weir Commission was appointed by the last Government to examine the economic and other aspects of the problem of electrifying the main railway lines of Great Britain. The report was published in March of last year, and confirmed the views of those engineers who held that electrification would lead to important economies and would be a boon to the country. The working results obtained by several electric railways in other countries also support this conclusion. In France particularly the electrification of the main lines has been very beneficial. It is pointed out that although Great Britain was the pioneer of steam railways it lags behind several other countries in electrifying its railways.

Sir Philip Dawson has made special studies of the main lines of the London, Brighton and South Coast Railway and of a project for electrifying the greater part of the main lines of the Great Western Railway. He finds that for slow goods trains the mean velocity is increased 30 per cent by using electric traction, and that for ordinary passenger trains the mean speed can be increased 25 per cent. The cost of repairs, renewals, and upkeep of locomotives is approximately 40 per cent of that of steam railways. This agrees closely with the estimates made by other engineers. Adding together the total capital required for electrifying all the railways in Great Britain, the economies directly attributable to this change would show a gain of 7-10 per cent upon the capital employed.

The quantity of energy necessary to supply a railway depends on local conditions and on the 'ton miles' required by different kinds of trains. A rough estimate can be made of the cost by examining the corresponding costs of electric railways abroad. Taking this as a basis and assuming the average cost of the ton mile on British railways, it is estimated that the 'maximum demand' for direct current from the railway substations would be of the order of 1·5 million kilowatts. To get the average load the mean factor is assumed to be 0·5. Hence the annual consumption on the d.c. side of the railway substations would be about 6500 million kilowatt hours a year.

If the electrification of the railways of Great Britain were begun at once, it would be finished by 1950. Assuming that the expected load on the 'grid' at that date is realised, the demand of the railways would be a fifth of the total output from the grid. The maximum of the railway demand from the grid would be about ten per cent of the total demand. To convert the standard three-phase a.c. supply into direct current, mercury rectifiers would probably be employed. Assuming that this is done, the efficiency of the conversion would be 84 per cent. Estimating that the cost of a kilowatt hour at the generating station would be 0·25*d.*, the cost for the d.c. unit supplied to the railway would be 0·495*d.* This compares excellently with the 0·5*d.* unit given in the Weir Report. Adding on the cost of operating the substations, we find that the total cost would be 0·55*d.*

The regular supply of energy taken by the electrified railways from the grid would react most favourably by lowering the general price of electricity. The electrification would necessitate the construction of about ten new power stations, for which the cost would be appreciably less than that of existing stations, thus contributing to the general lowering of the price of electricity. The necessary great increase in the number of substations would make it possible to supply electricity economically for general purposes to new areas. It will be seen that the conclusions Sir Philip Dawson draws will encourage railway engineers to proceed with their electrification schemes.

Obituary

PROF. GRAHAM LUSK, FOR.MEM.R.S.

AN investigator whose enthusiasm in the pursuit of knowledge never waned; a man who never wavered from the high standards of work and conduct which he set for himself in youth, and whose qualities of mind and heart endeared him to all; a teacher who always gave of his best: such was Graham Lusk. As such he will be greatly missed in many centres by a multitude of colleagues, friends, and pupils. From the beginning of his adult life to its end—for more than forty years—he devoted himself to the study of the problems of

animal metabolism and nutrition. His first paper, published in 1889, dealt with human diabetes, and his last, in 1931, was concerned with the influence of the thyroid upon phloridzin diabetes in the dog. Lusk himself found pleasure in remembering that in 1871 a paper of his father's upon diabetes was published, so that in each decennium for sixty years articles on that subject bore the family name.

Graham Lusk was born at Bridgeport, Connecticut, on Feb. 15, 1866. His father, W. T. Lusk, was a physician of high professional and social standing, who before and after the American Civil War, in which he took part, studied at many European centres. On his advice his son refrained from taking a medical degree, as the deafness from which the latter suffered, then and always, would have made professional practice difficult.

The elder Lusk had a firm belief in the importance of chemistry to physiology and medicine, and Graham therefore went to Germany to obtain, as he himself has said, a sufficient knowledge of physiological chemistry to give him a broader background than that possessed by the medical chemists of the day. At the age of twenty-one years he went to Munich to work under Carl Voit, but found that he could not at once enter the research laboratory. He had first to spend a year in listening to Voit's lectures and in attending so-called practical classes, in which students stood for two hours watching the professor perform experiments. After this probation he was allowed to join the research community, and from the first made a good impression upon Prof. Voit and his staff. The first product of his work was the paper on diabetes already mentioned.

Lusk acquired great affection for Voit, and never failed to speak and write of him with praise and gratitude. He displayed equal loyalty to his other great teacher, Max Rubner, with whom he continued a lifelong friendship.

Lusk's own work, carried out first at Yale and then for more than thirty years at Cornell Medical College, where he held the chair of physiology, reflected the influence of the two teachers he so much admired. It combined the methods that each of these in turn had developed for the study of metabolism: Voit's chemical technique and Rubner's appeal to calorimetry. Lusk's employment of the latter came for the most part after the first classical experiments of his American *confrères*, Atwater and Benedict, had been done; but while these were mainly concerned with the energy balance-sheet of human metabolism, Lusk used the calorimeter rather as a control for chemical studies.

Lusk explored very many aspects of metabolism. Among his special interests were the fate of ingested carbohydrates and the sources of endogenous sugar. His first work under Voit had brought evidence against the then current contention of Pflüger that sugar could not arise in the body from protein. In the early 'nineties, controversy on this point was so bitter in Germany that Voit was astonished to hear that Pflüger had consented to speak to the young author of the work in question! It fell to Lusk in later years not only to supply some of the evidence which finally compelled the conversion of Pflüger, but also to give precision to our knowledge of this incident in metabolism by determining with exactness the maximal amount of sugar which each individual amino acid from protein can yield in the animal body. This he did by administering known amounts of each to phloridzinised dogs and estimating the extra sugar which the animal excreted in consequence. He made indeed, during the course of several years, an intensive study of phloridzin diabetes, and thereby acquired important information concerning various aspects of metabolism.

An aspect which long interested Lusk was that which Rubner had termed the 'specific dynamic action' of foodstuffs. As is now so well known, the consumption of food, but especially the consumption of protein, increases *per se* the heat output of the resting body. If what we now call the basal metabolism of a typical animal be taken as 100 calories per day, and if these 100 calories be administered to the animal in the form of each of the several foodstuffs on different days, then the heat production of the still resting animal after receiving meat protein will rise to about 130 calories, after glucose to about 106 calories, and after fat to about 104 calories. These, according to Lusk, are typical average results. Rubner's explanation of the high figure for protein was that the extra heat corresponded to the free heat of certain thermal chemical reactions in *intermediary* metabolism, probably localised in the liver and representing energy not available for muscular or general tissue activity. Protein differs from carbohydrate and fat in that, whatever the current nutritional needs, the products of its digestion promptly undergo change in the body; a fact demonstrated by an immediate rise in the excretion of nitrogen. Unlike fat or carbohydrate, protein when administered in excess of contemporary needs is not stored as such, but only that moiety is stored which is capable of yielding sugar and therefore glycogen. In any event, the nitrogen of its products is removed before they serve as a source of utilisable energy. Such preliminary reactions thus give origin to that output of heat which is independent of activity.

Such was Rubner's view, and Lusk set himself to obtain experimental evidence in support of it. Unexpected results, however, led him to hold for a time a quite different view of his own. He studied the specific dynamic action (in Rubner's sense) of individual amino acids from protein, and established the interesting fact that while the administration of some among them causes a marked increase on the output of heat from the body, others have no such effect. Rubner, rather over-simplifying a statement of his views, had suggested that the extra heat of protein administration might be considered to come from the direct oxidation of that part of its molecule which is incapable of conversion into sugar. Lusk thought he had disproved this. Glycin and alanine, for example, he

to exert a marked specific dynamic action, while (as could be demonstrated in the phloridzinised animal) they can nevertheless, after de-amination, be wholly converted into sugar. On the other hand, glutamic acid exerts no dynamic action whatever, and yet only three out of its five carbon atoms appear in its yield of sugar. Such results as these, together with other experimental evidence, led Lusk to believe that the extra heat output which follows on protein consumption is due to a direct stimulation of general tissue activity. The stimulus is due to certain constituent amino acids or to certain primary products of their breakdown.

Such a view, if confirmed, would have justified the term 'specific dynamic action' better than the conceptions of its originator. Nevertheless, further work by Lusk himself, and some by others, has rendered the view untenable. Other explanations have been since advanced, but none seems entirely satisfactory. It is probable that the contributory happenings are complex, and that we at present lack sufficient knowledge of the chemical details of intermediary metabolism for full understanding of the phenomenon in question.

I have dwelt upon Lusk's dealings with this elusive problem because it was one which greatly interested him, and his study of it well illustrates his method of applying calorimetry to matters of detail. He never had any difficulty about giving up a theory of his when it ceased to account for facts. He said it cheered him to remember Marat's characterisation of Lavoisier, "a charlatan . . . who changes his theories as he does his shoes". In successive editions of his book he is always frank in admitting a personal change of view, and in the last he deals faithfully with all the evidence bearing upon the nature of specific dynamic action so called. This book, the "Elements of the Science of Nutrition", of which the fourth and last edition was published in 1928, is encyclopædic in its dealings with the literature. It lacks perhaps logical sequence in presentation, and the relative value of conflicting evidence is sometimes left unappraised; but it is written without bias, and contains abundant suggestions which have stimulated research in many quarters.

Lusk was too gentle to be a severe critic, but he was capable of intense indignation upon adequate cause. Certain opinions concerning aspects of metabolism he held with extreme firmness. He would not, for example, admit that fat could be converted into sugar in the body, and refused to believe that sugar is the sole immediate source of energy for muscular activity.

It will be recalled that, together with R. H. Chittenden, Lusk represented America on the Inter-Allied Scientific Food Commission in 1917. He frequently visited Great Britain, where he and Mrs. Lusk had many friends. Shortly before his death, on July 18, he expressed his deep appreciation of his election to the foreign membership of the Royal Society, and the Society itself will be always glad that the honour was offered in time to give that pleasure.

F. G. H.

SIR WILLIAM WILLCOCKS, K.C.M.G.

WITH the death of Sir William Willcocks, on July 28, there passed out of the engineering world and Egyptian everyday life one of the original band of engineers who helped to rescue that country from the financial bankruptcy into which it had been led by Ismail Pasha. Born in India in 1852, Willcocks passed brilliantly through the Thomason Engineering College, Roorkee, and gained his first irrigation experience in that country during eleven years' service with the Irrigation Department of the United Provinces.

Willcocks was brought to Egypt in 1883 by Sir Colin Scott Moncrieff, and at once devoted himself to the reorganisation of the irrigation system on which that country's prosperity almost entirely depends. On arrival he was given charge of the provinces of Gharbieh and Menoufieh, which lie in the Delta between the two branches of the Nile and are among the richest of the provinces. He immediately realised the urgent necessity for the construction of regulating works at the heads of canals so as better to regulate their flow and at the same time reduce the enormous silt deposits which not only impaired their efficiency but also called for intensive work of clearing by the forced labour system known as the 'corvee'. It was not long before this imposition, which had annually compelled 230,000 men out of a total population of 6,000,000 souls to work for about 170 days without pay, was abolished.

Willcocks' district then covered an area of some two million acres. With characteristic energy he used to tramp all over the country on foot, and soon became a familiar figure and almost a household word with the 'fellaheen'.

It was on account of his resourcefulness and courage that Willcocks was entrusted with the diagnosis of the 'disease' which, since their completion in 1861, had beset the two barrages, or dams, which Mougel Bey had designed and built at the heads of the Rosetta and Damietta branches of the Nile. Before they had been repaired, he courageously used them for raising the water level so as to give the canals a more plentiful supply. This was achieved by throwing a bank of loose rubble across the bed of the Rosetta barrage, thereby reducing the pressure of water which it had to bear, and, although signs of weakness did develop, the country profited for that season. The reconditioning of the barrages then followed. He was responsible for the remodelling of many canals and their attendant regulating works.

Having done so much to improve the system by which water is distributed, Willcocks was asked to devise a scheme for supplementing the supply of water at seasons when the natural flow of the Nile is deficient. His surveys of Nubia which resulted from this campaign, and his measurements of the flow of the Nile, find their parallel in the work done by the 'savants' of the Napoleonic expedition. The principles which he enunciated were those finally adopted in developing the Assuan reservoir scheme, which has up to the present day been

Egypt's only artificial reservoir. To engineers in Egypt, and in fact all over the world where irrigation is practised, his writings, reports, and principles have provided inspiration and guidance.

In 1901 Willcocks turned his attention to the irrigation of an area of three million acres in South Africa, and in 1911, after he had retired from the Egyptian Government service, he concentrated on the development of irrigation in Mesopotamia. He lost no time in giving practical effect to his schemes for the Hindia Barrage, and its attendant canals were already in operation before the outbreak of the War, and his maps and surveys proved of great value to those engaged in the campaign.

On the completion of the Assuan Dam, Willcocks was made a C.M.G., being later rewarded with the K.C.M.G. for his services in South Africa.

Willcocks was fond of controversy. In consequence of his strong personality he was somewhat intolerant of adverse opinion, and while there can be little doubt that his outspokenness estranged him from many people, subsequent events have vindicated many of his opinions, and the final account, when struck, will probably show a balance largely in his favour. Egyptians and engineers in general will mourn the death of a man to whom they are deeply indebted. A. B. B.

WE regret to announce the following deaths:

Prof. Louis W. Austin, of the staff of the U.S. Bureau of Standards, who was an authority on physical measurements and radio transmission, aged sixty-four years.

Sir William E. Clegg, C.B.E., pro-chancellor of the University of Sheffield and chairman of the Applied Science Department of the University, on Aug. 22, aged eighty years.

Prof. Harold Jacoby, formerly professor of astronomy at Columbia University, known especially for his work in the application of photography to astronomical research, aged sixty-seven years.

Mr. Herbert Knapman, registrar of the University of Reading, formerly lecturer in mathematics in University College, Reading, on Aug. 14, aged fifty-two years.

Foreign Guests of the British Association at York

THE following is a list of foreign visitors to the British Association for the York meeting who are attending in an official capacity either as guests or as representatives of foreign associations: *Section A* (Mathematics and Physics): Dr. W. Meissner, Physikalisch-technische Reichsanstalt, Berlin-Charlottenburg; M. le Duc de Broglie, Paris; Prof. W. J. de Haas, University of Leyden, Holland. *Section B* (Chemistry): Prof. J. Meisenheimer, Chemical Institute, Tübingen; Prof. H. Staudinger, University of Freiburg im Breisgau; Prof. Max Bergmann, Technical High School, Dresden; Prof. H. Kessener, The Hague. *Section C* (Geology): Prof. P. Pruvost, University of Lille. *Section E* (Geography): Dr. J. Georgi, Hamburg. *Section H* (Anthropology): Dr. Axel Boethius, director of the Swedish School of Archæology, Rome. *Section J* (Psychology): Prof. R. H. Wheeler, University of Kansas, United States. *Section K* (Botany): Dr. G. E. du Rietz, University of Uppsala, Sweden. Prof. Oswald Veblen, of Princeton University, is attending as the delegate of the American Association for the Advancement of Science, while Prof. D. A. Keys will represent the Royal Society of Canada. The South African Association for the Advancement of Science will be represented by Prof. J. E. Duerden.

Baron von Zach, 1754–1832

AMONG the men of science who fell victims to the epidemic of cholera which raged in Paris a century ago were Sadi Carnot (NATURE, Aug. 20, p. 266), and the Hungarian astronomer, Franz Xaver, Baron von Zach, who died there on Sept. 2, 1832. Born at Pesth on June 4, 1754, von Zach served for some time in the Austrian army, and from 1783 until 1786 was tutor in London in the family of the Saxon Ambassador, John Maurice, Count of Brühl (1736–1809), who was himself an amateur astronomer. One outcome of von Zach's visit to England was the discovery by him, under a heap of rubbish in an old stable at Petworth Castle, Sussex, of some manuscripts of the seventeenth century mathematician, Thomas Harriott. In 1786 he entered the employ of Ernst II. of Saxe-Gotha, and five years later became director of the observatory on the Seeberg at Gotha, afterwards the scene of the labours of the famous Hansen. With Bode, Olbers and Schröter, von Zach did much to revive interest in astronomy in Germany, and the *Monatliche Correspondenz*, which he founded in 1800, is referred to by Miss Clerke as "the first really effective astronomical periodical". He edited both this and other astronomical and geographical journals, and he was largely instrumental in stimulating German astronomers to search for a planet between Mars and Jupiter, a search which resulted in the discovery of the asteroids. The first of these, Ceres, was found by Piazzi at Palermo, but the second, Pallas, was discovered by Olbers at Bremen, while the third and fourth were likewise seen first by the German astronomers. Von Zach was also known as a teacher of astronomy. In 1804 he became grand-marshal of the palace of the duchess-dowager of Gotha, and after her death in 1827 lived for some years at Berne.

Application of Science to Economic Problems

THE recognition of the profound change in the whole structure of our civilisation, in its international relations as well as in the nature of production, is an essential condition for the elaboration of measures of recovery. The pamphlet recently issued under the title "Whither Britain: A Radical Answer" (London: Faber and Faber, Ltd., 1*s*.), and out[illegible]

some extent policies in development of those suggested in "Britain's Industrial Future" four years ago, frankly recognises these changes and accepts the necessity of adapting the structure and policies of society to meet the problems which arise. The authors of these papers have no quarrel with science as such, but rather recognise that science must play an important part in the planning and reconstruction which are essential for the continuance of our civilisation—that indeed modern science rightly applied could raise the standard of living to heights previously unknown and supply the material resources for a more abundant life for all. This is evident in their emphasis on science as a first major factor in agricultural policy, and their conviction that development of scientific research, its application to farming and improved marketing, are essential to the future prosperity of British agriculture.

The value of international industrial agreements is recognised, while imperial industrial agreements including imperial research are suggested as a line of promising development. While repudiating a policy of tariffs, this Liberal group advocates a system of national planned development comprising a national industrial commission with industrial and agricultural councils not unlike the Industrial Parliament visualised by Capt. Harold Macmillan in his scheme of creative protection. They argue further, however, that the State should also foster industry by keeping the demands for its products at a high economic level through well-planned social service and a constructive policy of national development. The perils presented by economic nationalism are not overlooked, and a paper on the international framework surveys the various problems such as disarmament, minorities, treaty revision, war debts, population, and migration, in which international co-operation and understanding are essential if progress is to be made. Even those scientific workers who, on the question of tariffs, differ most widely from the authors of these papers, should find much that is interesting and stimulating in their frank and virile statement of policy in the light of the actual facts of the present situation.

World-wide Telephony

At the International Electrical Congress recently held in Paris, several important papers were read on telephony. B. Gherardi and F. B. Jewett discussed 'world telephony'. The history of the subject illustrates how great discoveries occur at various intervals of time. Each of them causes a revolution in practice and between the intervals the process of applying the new inventions goes on continuously in the economic field. Such epoch-making discoveries were the invention of the thermionic tube, the permalloy series of nickel-iron alloys, and the discovery of paragutta. The use of paragutta has reduced the transmission losses to one-thirtieth of their former value. Many difficulties remain for engineers to overcome. For telephony between North America and Europe, 'long' radio waves are most suitable, but there is the fundamental restriction that there are only twenty 'ways' available owing to the limited breadth of the band of frequencies that can be utilised. With 'short' wave-lengths, the best wave-length to use depends on the hour of the day and the season of the year. Hence three wave-lengths are usually assigned to each circuit, and this limits the number of ways. Short-wave transmission is still in the first stage of its evolution; interruptions due to the vanishing of signals and to magnetic storms occur not infrequently, especially when the waves go through polar regions. The difference in local time between many large towns is a great inconvenience. There may be no overlapping in time between their working days. The language difficulty, although of less importance, is still a hindrance to progress. Many conversations are held between speakers in a language which neither knows well. In this case it is necessary that the clarity of the transmission be much better than when each is speaking his own tongue. Technical progress has now made possible communication between countries and continents. Whether this will be a boon to humanity or not depends on the nature of these communications.

Prof. Piccard's Ascent into the Stratosphere

On Aug. 10, Prof. A. Piccard, of the University of Brussels, accompanied by M. Max Cosyns, ascended at about 5 A.M. from Dubendorf Aerodrome, near Zurich, in a specially constructed balloon. He rose to a height of 16,700 metres (about 10½ miles), thus penetrating well into the stratosphere, and, after a twelve hours' flight, landed at Cavallaro di Monzambano, which is about ten miles south of Lake Garda. Among the equipment of the balloon was a wireless set, by means of which Prof. Piccard sent messages to surface observers. It will be recalled that this was Prof. Piccard's second ascent, his first having been on May 27, 1931, when he reached a height of 9¾ miles. As was to be expected, the aeronauts suffered considerable discomfort. The greatest trouble was the intense cold encountered in the stratosphere. Prof. Piccard states that he has made a number of observations which he hopes will prove of great value, but of any scientific results it is too early to speak. During his previous flight, Prof. Piccard had hoped to obtain evidence of the cosmic rays under more favourable conditions, and any contributions that he may be able to make in this field, from this flight, will be awaited with interest. Meteorologists look forward to the announcement of Prof. Piccard's results, especially if he has been able to make any observations on the composition of the atmosphere within the stratosphere; for, in spite of the observations already made by self-recording instruments on unmanned balloons, very little is actually known at present about this region.

Trans-Atlantic Flight from East to West

After waiting for some days at Portmarnock Strand, Co. Dublin, for suitable weather conditions, Mr. J. A. Mollison started on Aug. 18 at 11.30 A.M. on a solo flight across the Atlantic. His original intention was to strike the coast of North America, fly on to New York, and, after a short rest, to fly back across the Atlantic, thus making a round trip in about

three days. After thirty hours of flying, Mr. Mollison landed successfully at Pennfield Ridge, New Brunswick; it appears that he had sufficient fuel to go on, but was obliged by fatigue to come down. He was flying a Puss Moth aeroplane with a 120 h.p. Gipsy engine, such as is supplied to private owners, with the exception that the passenger seat has been replaced by petrol tanks. It is stated in the *Daily Mirror* that the direct costs of the flight were only £10 6*s*. 3*d*. for petrol and 15*s*. for oil. Mr. Mollison is the first to cross the Atlantic from east to west in a solo machine, which, incidentally, is the smallest to accomplish the crossing. The flight is a noteworthy tribute to the endurance of both man and machine.

Late Bronze Age Settlement in Shetland

A LATE bronze age settlement of considerable extent has been brought to light by excavation under the Office of Works at Sumburgh, at the southern end of the Shetlands. Previous excavation had revealed an iron age site, dating from about the beginning of the Christian era. During the present season, according to a correspondent in the *Times* of Aug. 19, six weeks' excavation has completely cleared one dwelling, partially cleared two more, and indicated the existence of others. The completely excavated dwelling shows evidence of four occupations, of which the third, as is shown by broken clay moulds, was much taken up with bronze-casting. It is 31 ft. in length, has an original and a secondary entrance, and three chambers with four lesser chambers opening out of them. The walls are three feet high and are built of selected pebbles from the shore, neatly fitted and without filling, except in the lower courses, where clay has been used to keep out the damp. Slate was much in use for tools. Both slate and stone implements show types not in use on the mainland. Of the partially excavated houses, the walls of one pass under those of the excavated house, and are therefore older. Slate was in use here. Though pottery is scarce, the ornament on one sherd gives a bronze age date. The second partially excavated dwelling is older again; but a sword and pottery of the type of Heathery Burn Cave, Co. Durham, still point to the late bronze age. Although the full extent of the settlement is not yet revealed, the existence of several other dwellings has been noted. When excavation is complete, the settlement will probably prove the most elaborate in plan of any known bronze age dwelling-place in Britain.

Roman Villa at Southwick

IT is announced that the Roman villa at Southwick has been given to the Sussex Archæological Trust with the object of ensuring its preservation. The villa is one of a chain of Romano-British buildings, probably farms, on a four-mile belt of fertile land south of the Downs, the others being at Kingston, Portslade, West Blatchington, and Brighton. The site has been excavated by Mr. S. E. Winbolt and others, with the aid of the Sussex Archæological Society. It was found to consist of a triangular block of buildings enclosing a courtyard approximately 200 ft. by 130 ft. The chief rooms are on the north side, where they are protected from the wind by the Downs; while verandahs on the sunny side face the sea. The buildings are solidly constructed, with walls 2 ft. and 3 ft. thick, and consist of rubble cores faced with flint. The site is at present unfenced; but as soon as funds have been raised, the northern portion containing the main buildings, which unfortunately is separated from the southern by the new road, will be fenced and reconditioned to enable the public to be admitted at a small fee. The Trust, to which the site has been handed over, was formed in connexion with the Sussex Archæological Society for the preservation of the ancient monuments of Sussex, and already holds in trust Lewes Castle, Wilmington Priory, the Long Man of Wilmington, the Marlipins at Shoreham, and Oldland Mill at Keymer.

Earliest known Pueblo Dating

DR. FRANK H. ROBERTS, Jr., who is in charge of an expedition of the Bureau of American Ethnology excavating Pueblo settlements on a site near Allentown, Arizona, is reported by Science Service, of Washington, D.C., to have obtained from one of the houses he has excavated beams which, according to the tree-ring chronology, were cut in the year A.D. 797. This is the oldest date for which evidence has been found in Pueblo ruins in the south-western United States. The dwelling was a pit-house, built largely underground, with an entrance through the roof. It had been destroyed by fire, the inhabitants leaving most of their belongings behind them, including much pottery. The oldest dates previously established by means of the tree-ring calendar elaborated by Prof. Douglass were A.D. 919 from a beam at Pueblo Bonito, and A.D. 861 from a piece of timber at Una Vida. Both these sites are situated in New Mexico.

Electric Tramcar Systems

ABOUT the beginning of the present century many local authorities undertook the installation of electric tramway systems in cities and towns, and many workers reaped the benefit of this system of transport. The coming of the petrol bus has led many to think that in a few years' time tramways will disappear. Their immobility often causes tramway congestion, and intending passengers have to cross a stream of traffic in order to board them, unless this stream be temporarily arrested. When one sees the great part played by tramcars in cities like London, Glasgow, and Manchester, and in many cities abroad, where tramcars with two or three trailers attached are continually going through crowded streets, it is obvious that it will be many years before they are obsolete. The large number of tramcars in Austria which were installed more than twenty years ago on the supposition that vehicles would always drive on the left-hand side of the road has led to difficulties in certain districts where one must now drive on the right-hand side. The cost of obtaining uniformity by altering the tramway lines in Austria is prohibitive at the present time. Just as in the case of weights and measures, what has been done in the past

difficult and expensive to introduce uniformity in the future, no matter how desirable proposed changes are. The advent of the trolley bus, which is much more mobile than a tramcar, will doubtless be a great help in the many years which will have to elapse before tramways become obsolete. Their popularity in Great Britain is due partly to the fact that, like electric tramways, they get their power from stations which burn coal obtained at home and not a foreign product like petrol.

Radio Equipment for Deep Sea Trawlers

FEW realise what a great boon radio equipment is to deep sea trawlers. Some of these small vessels fish at all times of the year on fishing grounds many hundreds of miles away from their home ports. Trawlers from Hull and Grimsby regularly fish off Bear Island near Spitsbergen; others trawl in the Davis Straits, 2400 miles from their base, and some off Iceland and in the White Sea. During the winter, which is the best fishing season, it is nearly always dark, and the gales and the intense cold make the work very hazardous. Catches vary considerably and the markets are sometimes glutted and sometimes short of supplies. It is of the greatest importance that the trawlers of the same company should be in close touch with one another, and this they can do by radio telegraphy. In the Engineering Supplement to *Siemens' Magazine* for March a discription is given of a radio station for use on board trawlers. The whole of the apparatus is contained in a teak case which can easily be passed through hatchways of normal size. This can be fitted into quite a small cabin or even into a cupboard. It receives and sends messages on wave-lengths between 20 and 20,000 metres, the required electricity being obtained from primary batteries and a small alternator. The output of the alternator does not exceed 300 watts, but the range with coast stations is often of the order of 1000 miles. In addition, Messrs. Siemens have designed a 'direction finder' which is simple to operate. Many trawlers also have a Marconi depth finder so as to enable them to locate the places where the required fish are likely to be found. Recent inventions have made the life of the trawlerman much easier and much more secure.

A High Voltage Electrostatic Generator

IN the August number of the *Scientific American*, there is a short account of the new electrostatic generator which is being built by R. J. van de Graaff at the Massachusetts Institute of Technology. From this and some notes which have appeared elsewhere, it seems that it is a large-scale elaboration of the Wimshurst type of machine, consuming considerable power in its operation. The discs of the Wimshurst machine are replaced by silk belts, and the separation of charges made regenerative. The charges are collected on enormous metal spheres, sufficiently large to hold an experimenter and apparatus, and capable of being charged to 10-15 million volts without flashover. Details of the power available for such experiments as those of Cockroft and Walton of the Cavendish Laboratory, Cambridge, are not given, but it is to be presumed that calculations have been made on the basis of Gamow's theories of the artificial disintegration of nuclei which justify the undertaking. The return to Faraday's device of sitting within highly charged apparatus is interesting.

Night-Crowing of Cockerels

A COMMUNICATION by D. Sinitsin on the night-crowing of the cock, published in Russian in 1924, in the Records of the Bielorussian Institute of Agriculture, attracted the attention of the late M. Bigourdan, the veteran French astronomer. Shortly before M. Bigourdan's death, Mr. Sinitsin provided him with full information on the subject. Mr. Sinitsin (1750 Wilton Place, Hollywood, California) has now sent to the Editor a record, illustrated by a diagram, of the fourteen nights' crowings of a cock kept in his study at Minsk, Russia, in 1923. Regular crowings occurred between 11 P.M. and 5 A.M., when they could be measured by hours, each crowing coming within ten minutes of the hour; before 11 P.M. there was no crowing, and after 5 A.M. it was not regular. Changes of atmospheric pressure, music, light, and talking in the room did not affect the regularity. The second and third crowings, especially when at 2 and 4 A.M., were the most vigorous and accompanied by flapping. It is suggested that the paroxysms of crowing are caused by something in the atmosphere perceived by the cock in some unknown fashion, and that it is connected with the rotation of the globe, waves from the sun-lighted side of this spreading to the darkened side. It is also put forward that the twelve-system of time-reckoning had its origin from the period when time could only be measured at night by cock-crowing, and that by artificial selection a race of cocks might be produced which would tell the time with clock-like regularity.

Meteorology of the Past, Present, and Future

SIR NAPIER SHAW (*Scientia*, June 1932) characterises the meteorology of yesterday by the accumulation of climatological data, their discussion in connexion with the general circulation of the atmosphere, and their analysis by the methods of harmonic analysis and coefficients of correlation. He emphasises the past concentration of attention on depressions and anticyclones, and the doubts which arise in connexion with reduction of pressures to mean sea level. The meteorology of to-day is essentially concerned with the interactions of air currents of different origin at the surface of separation which is known as the 'polar front', the methods of discussion being associated with the Norwegian school of meteorologists. The meteorology of to-morrow is, in Sir Napier's opinion, to concern itself with entropy as the specification of the qualification of any mass of air for its position. The name 'weather potential' is suggested as another name for entropy. Sir Napier suggests that all motion in the atmosphere, apart from penetrative convection, is along isentropic surfaces, so that these surfaces act as automatic guides to all moving air, in much the same sense that the banks of a river act as automatic guides to the water in the river. He also suggests, though very briefly, that regions of high and low pres-

sure in the atmosphere are created by currents of air associated with straight isobars, in which the velocity is not of the right amount to produce a balance between pressure gradient and the deviating force due to the earth's rotation, and that the effect of gravitational forces on masses of air, the entropy of which differs from that of their environment, can develop a column of low pressure.

The People's Cinema University

A leading recommendation of the Commission on Educational and Cultural Films which was set up in 1929 was the establishment of a National Film Institute (see Nature for June 18, p. 911). One is interested, therefore to observe the scheme evolved by Sir James Marchant and Sir Oswald Stoll for the establishment in London of the People's Cinema University. The university, it is stated, would consist of a central building, from which lecture halls equipped with sound-film installations for the regular exhibition of films would radiate. In the central dome there would be a Zeiss planetarium. There would also be reading rooms, offices, etc., available for film patrons and societies. All these features are combined in an imposing general design prepared by Sir Giles Gilbert Scott. The films would be made in co-operation with an expert educational board to meet the requirements of teachers and scholars, and would be distributed and collected by motor cinema vans throughout the country. Projectors also would be supplied to schools, churches, and institutions. In his broadcast address and in letters to the *Times*, Sir James has directed attention to useful educational work already accomplished. The catalogues issued by Visual Education, Ltd., indeed, list quite an impressive series of educational and cultural films. Sir James believes, therefore, that the time is ripe for such a venture as the People's Cinema University, which, in its own sphere, would attempt work resembling that of the B.B.C.

Change in Colour of Birds due to Exposure

Mr. P. J. Norman, in *Cage Birds* for Aug. 6 (p. 70), cites a remarkable case in which a black-headed variety of the budgerigar, after being turned out into an outdoor aviary provided with a 'flight' or net-roofed annexe, so that the birds were exposed to rain if they wished it, has resumed the normal yellow colouring of the head. The breeder of this bird, it seems, has stated that all of its nest-fellows were also black-headed, and that these had retained the black head through a moult. The family had been bred indoors, in a cage, and it is suggested that in the case of the bird which reverted, the exposure to open air and rain in its new quarters had brought about the return to normal plumage. It would, however, be well worth while to see whether outdoor treatment would operate in this way with the rest of the brood; or, if they be still kept indoors, whether they will produce black-headed young. It may be noted here that of the first two specimens of the rare East Asiatic Derbyan parrakeet the London Zoological Society possessed, one became black-headed and afterwards reverted to normal, while its companion did not change, though both lived in the same cage indoors in the old Parrot House.

Helminthological Abstracts

One of the first fruits of the various agricultural bureaux formed by the Imperial Agricultural Research Conference has been the establishment of a number of abstracting journals, the latest of which to appear being *Helminthological Abstracts*, under the editorship of Prof. R. T. Leiper. This new journal, which is issued as a supplement to the *Journal of Helminthology*, differs in several important respects from the others. Papers are arranged by journals, not by subjects, and each abstract is printed so that the first sentence is in effect an extended title; the remainder is a succinct abstract of the chief results obtained by the authors. The *Abstracts* will be issued in five parts each year, the first of these being in April. This will enable a single volume to cover the entire literature for the calendar year, so that, in addition to keeping the current literature before the reader, it will when bound form a complete summary of the year's work. It is priced at 16*s*. 6*d*. a volume, post paid, and is obtainable from the Institute of Agricultural Parasitology, St. Albans. Another publication from the same Bureau is the "Bibliography of Helminthology" for the year 1930 (6*s*.). This volume contains references to more than 900 titles in 346 different journals. These titles are arranged by journals, with an adequate authors' index. The volume has the same format as the *Abstracts*, and although issued separately could be bound with the completed volumes to form an invaluable index to the journals abstracted and the authors of the papers.

Prof. Richard Willstätter

Die Naturwissenschaften for Aug. 12 is a special issue in honour of Prof. Richard Willstätter's sixtieth birthday. The memoir contains a series of articles by experts upon the fruitful results of his memorable researches in organic chemistry. Prof. F. Haber refers to the successful campaigns which Willstätter has conducted in different branches of biochemistry, for the exceptional skill which he displayed in elucidating chemical structures was principally concentrated upon problems closely related to living matter. Prof. Pummerer reviews the results of forty years of strenuous endeavour. First comes a masterly series of papers upon alkaloids, culminating in the synthesis of tropin and cocaine; then for a while aromatic structures claim attention, particularly quinone-imines, aniline black, and cyclo-octa-tetraene. But Willstätter's interest in plant life led him to the study of the compounds to which plants owe their distinctive colours. Thus chlorophyll, carotene, and the anthocyanins were investigated in turn, and the success attained in each of these branches led him to the further problem of assimilation by plants. This involved the study of enzymes, which has yielded some astonishing results in recent years. Prof. L. Zechmeister describes the main lines of Willstätter's work on carotinoids and the important hydro[illegible] carotene, which has come into prominence [illegible]

of its relation to chlorophyll and to vitamins. Prof. R. Robinson discusses in some detail the structures of anthocyanins, the red and blue colouring matter of flowers. Prof. R. Kuhn refers to the influence of Willstätter's work on the development of the theory of heteropolar rings, and Dr. Waldschmidt-Leitz describes the process of resolution of enzyme mixtures from the pancreas and from yeast by a method of selective adsorption. The concluding article upon chlorophyll and its derivatives is by Prof. A. Stoll and Dr. E. Wiedemann.

A New Periodical for Chemical Physics

As a part of its comprehensive programme of physics publications, the recently formed American Institute of Physics (see NATURE for Aug. 6, p. 199) announces that it will shortly begin a new publication to be called the *Journal of Chemical Physics*. The first number will be issued in January 1933. Primary among the circumstances which have led the Institute to undertake the new publication is the increasing number of articles on physical chemistry which have distinct bias on the physical side. These have not found a suitable outlet in any journal now in existence, being perhaps too mathematical for the *Journal of Physical Chemistry*, too physical for the *Journal of the American Chemical Society*, or too chemical for the *Physical Review*. Inquiries or suggestions concerning the new journal should be addressed either to Dr. Harold C. Urey, Department of Chemistry, Columbia University, or to the American Institute of Physics, 11 East 38th Street, New York.

Irrigation in India

THE progress of irrigation and the use of the available water are surveyed in the "Triennial Review of Irrigation in India, 1927–30" (Simla: Government Press, 2*s*. 6*d*.). It would appear that the monsoon of 1927 was almost normal in its time and rainfall except for a slight deficit. In 1928 there was a marked deficiency in the north-west, and in 1929 the principal departure from the average was an excess of 100 per cent in the rainfall of the North-West Province and Sind. During the three years under review, the average area irrigated by Government works in British India was 29,954,000 acres, an advance of more than two million acres on the corresponding figure for the previous triennium. The chief increase was in the Punjab valley, owing to the development on the Sutlej valley canals. It is noticeable that, of the total sown area, 12·7 per cent was irrigated. Among the most important projects now in hand are the Sukkur Barrage and canals in Sind, the Sarda canal and a hydro-electric power scheme on the Ganges canal in the United Provinces, and the Sutlej valley project in the Punjab. The problems of water supply in Baluchistan are being considered in the hope of improving the very poor irrigation facilities.

Commonwealth of Australia Yearbook

THE Yearbook of the Commonwealth of Australia contains a mass of descriptive and statistical which much is of considerable scientific value. The prevalent demand for economy has curtailed to some extent the size of the volume, but there is little evidence of its usefulness being impaired. The figures dealing with agricultural production are particularly full, vital statistics are given much space, and there is a long article, accompanied by distributional maps, on the climate and meteorology of Australia.

Announcements

PROF. R. RUGGLES GATES will deliver three De Lamar lectures at the Johns Hopkins University during the week beginning Oct. 24, on "The Principles of Heredity in Man, and their Application to Society".

IT is announced in *Science* that Prof. Rudolph W. Ladenburg, of the Kaiser Wilhelm Institut für physikalische Chemie und Elektrochemie, has been appointed to the Cyrus Fogg Brackett research professorship at Princeton University, in physics.

THE Society for Cultural Relations with Soviet Russia is considering the possibility of arranging a tour of scientific institutions in Russia, to leave London on Sept. 10. It is proposed to arrange for parties of British scientific workers engaged in physical, biological, and medical research, and for engineers, chemists, and anthropologists, to visit the corresponding institutions in Russia, and to meet Russian workers engaged in similar research. The total cost of the tour is about £35 inclusive, the time being approximately one month from departure to return to London. Further particulars and application forms may be obtained from the Secretary, S.C.R., 1 Montague Street, London, W.C.1.

MESSRS. W. and G. Foyle, Ltd., of 119-125 Charing Cross Road, W.C.2, have recently published a new catalogue of new and second-hand books on technical subjects and applied sciences. More than 450 subjects are represented. About three thousand books are catalogued, and the list should prove a source of help. The majority of the standard works are available, many of them being obtainable second-hand as well as new.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A headmaster for the Netherton Farm School, near Morpeth, Northumberland—The Secretary, 18 City Road, Newcastle-on-Tyne (Sept. 3). An assistant conservator of forests in the Department of Agriculture and Forests, Sudan Government—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S.W.1 (Sept. 5). A professor of zoology at the University of Bristol—The Secretary and Registrar (Oct. 1). A resident tutor of chemistry, rural science, and school hygiene at the Winchester Diocesan Training College—The Principal. A headmaster of the Incorporated Thames Nautical Training College, H.M.S. *Worcester*—The Secretary, Ingress Abbey, Greenhithe, Kent. An assistant (woman), with analytical experience in organic and inorganic work, at the Air Ministry, Kidbrooke—The Secretary, (I.G.), Air Ministry, W.C.2.

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

A Correlation of the Walden Inversion with the Pinacone and Beckmann Changes

THE esterification of an alcohol may be represented as involving decomposition of an oxonium salt (I.), which corresponds closely to a reaction of quaternary ammonium hydroxides (II.):

$$\bar{A} + \begin{matrix} X \\ Y \\ Z \end{matrix}\!\!>\!C\,.\,\overset{+}{O}H_2 \longrightarrow A\!-\!C\!\!<\!\!\begin{matrix} X \\ Y \\ Z \end{matrix} + H_2O\,;$$

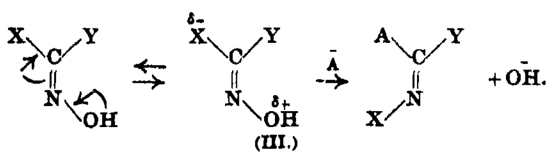
(I.)

$$\bar{O}H + \begin{matrix} X \\ Y \\ Z \end{matrix}\!\!>\!C\,.\,\overset{+}{N}Me_3 \longrightarrow HO\,.\,C\!\!<\!\!\begin{matrix} X \\ Y \\ Z \end{matrix} + NMe_3.$$

(II.)

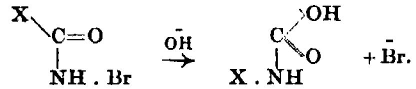
These reactions very possibly proceed by extrusion of a molecule of water or tertiary amine, consequent upon attachment of anion in virtue of a positive charge on the carbon atom derived from, or induced by, that on the oxygen or nitrogen.[1] It may, however, be anticipated that this latter rather than the derived charge will determine the result, and permit only a condition of electrovalence, when the direction of approach of the anion is such as to expose it to the operation of either. In other words, covalent union with carbon will be dependent on approach from the side of the molecule remote from oxygen or nitrogen, and inversion of configuration must occur. As Kenyon and Phillips[2] have emphasised, inversion in general is associated with reactions of the type now discussed, but it is clear that similar considerations are applicable to a negatively charged atom and a cation, and it is probably only on account of the difficulty of realising these latter conditions in practice that Walden inversions of this type have not been realised.

The relationship of the Beckmann change to the Walden inversion is indicated by the facility of each type of change in the cases of the *p*-toluene sulphonic esters of oximes and alcohols respectively. Since, now, the behaviour of the oximes towards substituting agents is comparable with that of phenol,[3] their isomerisation under the influence of strong acids may be attributed to formation of the system (III.):



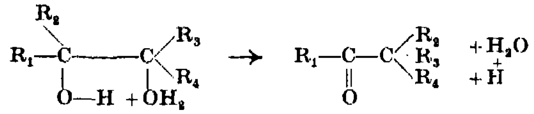
(III.)

The actual Beckmann change then represents an alternative possibility to the occurrence of depolarisation (by reversal of the initial change), which will be facilitated by the presence of a suitable anion to replace the migrating group X in its combination with the carbon atom. X in turn will promote detachment of hydroxyl or other ion from the nitrogen atoms. The analogy of this phase of the reaction to the changes referred to at the outset is obvious, and, accordingly, Meisenheimer's experiments[4] have led him to conclude that inversion occurs, in the sense that it is X rather than Y which migrates. Corroborative evidence in favour of this view is afforded by another reaction, which has long been connected with the Beckmann change, namely, the formation of amines from acid bromoamides and similar derivatives. The reaction is actuated by hydroxyl ions, and may thus reasonably be considered to be analogous in its first stage to the alkaline hydrolysis of esters,[5] involving extrusion of the group X with the pair of electrons requisite to enable it to preserve its configuration[6] and to displace bromide ion from the nitrogen atom:



As thus represented, the reaction is also not dissimilar from the benzilic acid change.

Like these, the pinacone and related changes also exhibit the characteristics requisite for an intramolecular Walden inversion, the negative change requisite for migration of the group R_2 arising from detachment of a proton from the hydroxyl group (or, in certain closely related changes, by attachment of an anion):



In this connexion, Kenyon and Phillips have already surmised that McKenzie's observations[7] on the preservation of optical activity in these types of changes, and in semipinacolinic deamination, are indicative of a Walden inversion.

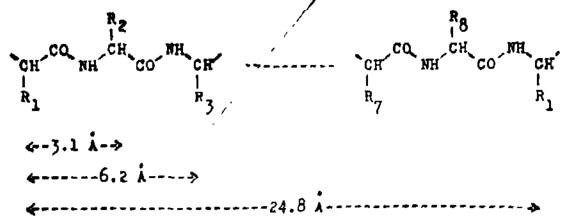
X-Ray Interpretation of the Molecular Structure of Feather Keratin

SOME two years ago it was shown in this laboratory that the quill of a feather gives rise to a complex but well-defined X-ray fibre photograph[1] which is quite different from that of animal hairs.[2] It was afterwards shown that a similar photograph is given also by tortoise shell, and the conclusion was formed that it is characteristic of the keratin of feathers and reptilian scales as opposed to that of mammalian hairs, nails, horns, spines, etc.[3] In the light of knowledge gained from the X-ray analysis of other protein fibres, it is now possible to interpret the feather photograph and fit it into the general scheme which such investigations, with increasing clearness, are beginning to unfold.

The details of the photograph need not be gone into here, and indeed have not yet been worked out completely, but it is clear now that it is only a rather bewildering elaboration of the type of photograph which is obtained from natural silk (fibroin)[4] and the stretched form of hair (β-keratin),[5] both of which have been referred to a polypeptide chain in a more or less fully extended state. The side spacings are similar, but there are indications of some ten hyperbolæ in the feather photograph. By the application of the principle of 'layer line enhancement',[6] the may be separated into sets grouped round

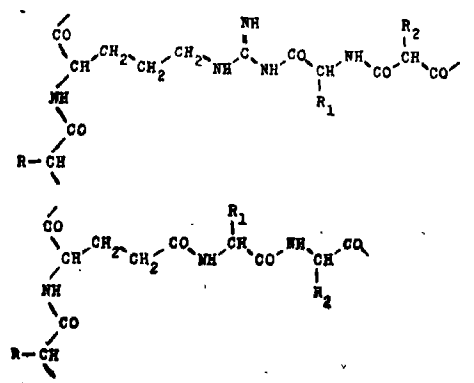
periodicity of (at least) 24·8 A., and secondary periodicities of 6·2 A. and 3·1 A., corresponding to the chain :



The last-mentioned spacing recalls the 3·5 A. found in fibroin and the 3·4 A. in β-keratin : we have shown that the difference is due to a slight folding of the peptide chain, analogous to that discovered in the unstretched form of hair (α-keratin),[3, 5] which must be due to a further inter- or intra-chain linkage of a resistant but non-rigid nature. We base this deduction on the striking observation that when the quill is stretched, its fibres are not ruptured until the spacings along the fibre axis have increased continuously by as much as 6 per cent. Stretching thus transforms the spacing, 3·1 A., associated with the length of a single amino-acid residue, into 3·3 A., which is only a little less than the value found in silk and stretched hair.

Interesting as is the molecular interpretation of feather keratin on its own account, its importance as a contribution to protein analysis in general is even greater, because of the powerful support it brings to the concept of the extensible protein chain. In view of the results here reported, any doubts as to the essential correctness of the conclusions to be drawn from the X-ray analysis of silk and animal hairs [4, 5] may now be set aside. The protein chain, as a long backbone of primary valencies decked out with numerous side-chains the interactions and cross-linkages of which can produce foldings of the main chain of widely varying amounts, may now be thought of as a definite stereochemical entity grown visible, like the cellulose chain and many other simpler molecules, in the light of the X-rays.

It is scarcely necessary to point out how many fascinating questions are involved in the comparative X-ray study of the molecular structure of hair and feathers, and in the significance of the sequence of eight side-chains in the longitudinal pattern of the latter. May it not be that the growth of feathers finds its origin in the development of further keratin chains by the formation of *lateral* peptide linkages ? From the side-chains of arginine and glutamic acid, for example, such outgrowths as the following are possible :



The investigations are being continued and will [...]ed in detail in due course. A complete chemical analysis of the type of feather under examination is also being undertaken in the Textile Chemical Laboratory.

J. W. Gregory

"Drowned by the capsizing of his canoe on the Urubamba." Thus has passed Prof. J. W. Gregory, at the age of sixty-eight years, continuing to the last his brilliant career of tireless exploration. British geology has lost one of its most intrepid leaders, and his fellow scientific workers the world over will miss his stimulating thought.

It is not my privilege to review the varied aspects of his life as administrator, teacher, explorer, and man of science. Although known to me through his observations in Africa, Australia, and Chinese Tibet, he remained an impersonal thinker among my colleagues until we had both passed three score and more. I first met him in his home at Glasgow when on my way to Africa to study the rift valleys, his own special subject.

We were then mutually aware of pronounced differences of opinion on theoretical questions, but the frank, cordial reception accorded me disarmed for all time any instinct of intellectual antagonism and quickly established happy relations. In long and earnest discussions, I found him a well-informed and aggressive opponent, strongly convinced of the essential soundness of the geological philosophy of Eduard Suess. His convictions were natural. In the fluid medium of speculation, where free-swimming facts may group themselves at will, ideas take forms determined by bent of mind and circumstance. The agreement between thinkers so unlike as Suess and Gregory illustrates the effect.

In Gregory's youth, Suess was already the master philosopher of European geology. Certain racial characteristics distinguished the younger from the older man, but there was between them an intellectual link in that both used their great powers of imagination creatively.

Suess was the embodiment of German *Gemütlichkeit*. He loved his home above all else. He had voluntarily become sessile, early in life. His scientific thought was contemplative. He read, absorbed, and moulded the observations of others to create the *Antlitz* of the world of his imagining. Gregory, by contrast, was intensely active. His habit of observation was objective. He travelled far and wide to accumulate facts. But he also possessed a creative imagination that was strong of wing.

While still a daring, enthusiastic youth (in fact he was never any other, where danger was concerned) Gregory explored the Great Rift Valley of East Africa and found it to be a tension rift. Suess, on the evidence of more casual descriptions, had conceived it to be part of a great rent, 4000 miles long, torn through Africa and Arabia by the subsidence of that part of the suppositional Gondwana continent which occupied the site of the Indian Ocean. Here was an agreement

of observation on the part of Gregory with the inference on the part of Suess, which could not but be convincing. The grandeur of the concepts appealed to Gregory's poetic thought, and he became for life an advocate of Suess's ideas of the development of the Indian Ocean basin by the foundering of Gondwanaland.

It is well known that weighty arguments in support of the general theory of lost continents may be adduced from palæontology, from the geological histories of Africa, Asia, and the Americas, as also from climatic changes throughout geological time. Gregory was master of them all. The scope of his knowledge was all-embracing. An eager student, a bold investigator, a rapid thinker, endowed with a capacious memory for facts and constructive capacity for synthesis, he became, as the result of his far-flung explorations, an outstanding authority on the world as a whole.

Gregory was, however, far from being a dogmatic theorist. Though tenacious and formidable in argument, he recognised the incompleteness of geological evidence and appreciated the obligation to consider advances in knowledge. In 1915 he wrote in " Geology of To-day " :

" In order to free geology from hopeless attempts to solve problems which could not be solved with the knowledge then available, and to get rid of the incubus of unscientific and premature hypotheses, a group of English geologists founded the Geological Society of London."

To that purpose he was loyal. In the words of Lyell, he conceived the ideal of the founders to have been " to multiply and record observations ", and to that end he dared every risk and devoted his life unsparingly.

Gregory passed, as he would have wished, in active service. He leaves a most eminent name in the roster of great British geologists, but it cannot fill the emptiness in the hearts of his friends.

Appearance of a Rusty-Red Pigmentation in the Coats of Albino Rats in the Tropics

SOME details of the appearance of a reddish pigmentation in the coats of certain rats after importation into Trinidad from London may be of interest to geneticists.

The colony lies between ten and eleven degrees north of the equator. The shade temperature during the day ranges from 85° to 95°. The night temperature is somewhat lower, especially in the dry season from December to March or April, when the lowest temperature is about 70°. The health of the rats was good. They arrived at the laboratory in November and December 1928. Forty-five were pink-eyed albinos, seven males and thirty-eight females; four were black-and-white, two males and two females, with the Dutch-rabbit distribution of pigment: these were all black-eyed. They were placed in roomy cages, four females to each male. No attempt was made to isolate the albinos from the black-and-white in the matings, as genetic experiments were no part of my programme. No alien blood of any kind was introduced. The only selection made was that animals varying in weight more than ten per cent above or below the average of their litter mates were discarded as unsuited for dietetic experiments.

The following notes were recorded :

January 1929; the albino offspring ($F1$) of the imported animals were of a creamy-yellow tint.

April 1929; second generation ($F2$) born. Some of the ratlings were reddish-yellow.

September 1929

Rusty-red-(or yellow)-and-white .	1[illegible]
Black-and-white (Dutch-marked) .	4
Black with white belly . . .	4
Total	80 rats.

A reddish strain of fancy rats similar to those described above and, like them, possessing pink eyes, is known to animal fanciers. These originated in Japan, coming, it is said, from Nagasaki, a place with a rather hot climate.

In May 1932, Dr. Wise, Surgeon-General of Trinidad, sent me some of the Trinidad red rats, descendants of those I had left there. These seem darker than those I saw last September. The eyes remain pink, and their bellies, though reddish, are lighter than the rest of the body. Four of this contingent are in a tropical house at Kew for breeding experiments.

On March 3, 1932, a male and two female albino Wistar rats from the Medical Research Council were sent to the same house to ascertain whether results similar to those found in Trinidad would be obtained. The conditions as to temperature and humidity are almost identical with those of Trinidad, the chief difference being the lesser amount of sunlight.

In a few weeks these rats showed a slight creaminess of tint, which was especially marked on the back of the neck.

Litters ($F1$) were born in March. These were all cream-coloured, in varying degrees of intensity. One male and two females of these were retained at Kew for breeding, the remainder being taken to the animal house at the London School of Hygiene and Tropical Medicine. In June, litters ($F2$) were born, these being distinctly darker than their parents. The Kew-bred rats grew darker in colour both when retained in the tropical house and when brought to the School, but this latter result may be partly due to the fact that the end of June and the beginning of July were hot.

In addition to these facts, and possibly standing in some causal relationship with them, is the occurrence of extensive gastro-intestinal hæmorrhage in rats living in Trinidad or in a tropical house at Kew, when given for a few days a diet of water only. A few animals on this diet in the temperate climate showed traces of bleeding, but not more than traces, whereas in the tropical climate the appearance of the intestines resembles red-currant jelly.

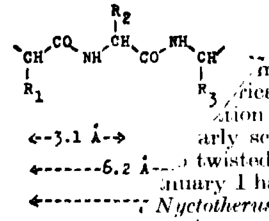
Cytoplasmic Inclusions of *Opalina* and *Nyctotherus*

A VERY interesting paper has recently appeared by Richardson and Horning,[1] on the cytoplasmic structure of *Protopalina* and *Nyctotherus cordiformis*. In the opalinids these authors distinguish three classes of inclusions: first, darkly staining rod-like stru
the mitochondria, often in close connex

periodicity of (at least) 24·8 A ive granules, which
periodicities of 6·2 A. and 3·1 A in form; and thirdly,
the chain: n preparations by the
and Cajal—fairly large
wisted and snake-like, and
he cytoplasm.
mitochondria[2] are numerous
rical structures, often showing a
tion; while the Golgi bodies are
arly scattered, and vary from rod-
twisted filaments.
nuary I have been working on *Opalina*
Nyctotherus cordiformis, both by means



The last eparations and *intra vitam* staining. In
in fibroi my silver preparations I find fairly large
that t ed bodies, more or less round in shape, near
pept ctoplasm but never in the central regions, and
twisted, snake-like in shape. These seem to be the same bodies as identified by Richardson and Horning as Golgi bodies; but I am not convinced that these bodies seen in my formalin silver material are the homologues of the Golgi bodies of Metazoa, both because of their dissimilarity to known types of Golgi apparatus and from failure to show them after many attempts with post-osmication methods (Lassanov, etc.). They may indeed be artefacts.

In chrome-osmium material I find both the rods and irregular bodies, but this also holds after many fixatives, even alcoholic ones; and also all gradations are found between these rods and irregular forms. Hence I have arrived at the conclusion that these are but two aspects of the same structure; they are not mitochondria, but are probably connected with the storage of food. The true mitochondria are small spherical granules, which stain *intra vitam* with Janus green, as well as being seen in chrome-osmium material.

In *Nyctotherus*, I have observed the same two categories of bodies as shown by Richardson and Horning; the larger (their Golgi elements), I have fixed with many methods (absolute alcohol, corrosive acetic, Flemming-without-acetic) as well as by silver techniques—slides, so made, were stained by Gram's method, and these bodies were proved to be Gram-positive bacteria, exactly like certain bacteria in the rectal contents. For this determination my thanks are due to Prof. Bigger of the Bacteriology Department, Trinity College, who carefully examined my slides. The smaller bodies, mitochondria of Richardson and Horning, were shown by similar fixatives and gave a Gram-positive reaction. It may be that they are mitochondria in which the protein base is particularly well developed, and hence they are not dissolved out by absolute alcohol.

It is hoped shortly to publish a full account of these observations.

Colonisation of the Sea by Insects

THOUGH insects are represented in almost every possible niche in terrestrial and fresh-water environment, very few indeed have colonised the sea. Besides *Halobates*, which is pelagic, only some chironomid larvæ and a trichopteron are known to be permanent inhabitants of the sea.[1] Many insects, however, can live in waters having a salinity equal to and even much higher than that of sea water.[2] This indicates that ...y is not a barrier to their migration, neither do ... currents and tides appear to be, since many insects live in torrential hill-streams which run with almost an equal, if not greater, force and velocity. Furthermore, many insects live on the sea shore[3] where the physical effects of tides are most pronounced.

In the autumn of 1930 and the spring of 1931, I made extensive collections in several salt waters of the Salt Range, Punjab. I obtained numerous specimens of insects from waters of a salinity 2·5 times as great as that of the sea. These insects included may-fly larvæ (*Claeon* sp.) and several hydrophilid beetles. The occurrence of may-fly larvæ in such highly saline waters is, I believe, recorded here for the first time.

A careful comparison of the detailed chemical analyses of waters from the Salt Range area with those of sea-water samples taken by the *Challenger* from different oceans of the world shows that the most important difference between the two is the comparatively low calcium content (1·16-1·20 per cent) of the sea water. In the salt waters investigated by me the percentage of calcium varied from 1·77 to 31·67, except in the San Sakesar Lake, where it was 0·11 per cent and in which no insect life was found. This definitely suggests that it is the low calcium content of sea water which has stood in the way of insects inhabiting the sea, and that it is the large amount of this ion in the waters of the Salt Range which helps insects in keeping their body fluids in equilibrium with the highly saline waters which they inhabit. This suggestion seems to be strongly supported by the work of Pantin,[4] Weil and Pantin,[5] and Pantin,[6] who in the case of estuarine animals showed that calcium has a profound influence on their permeability to water and salts. McCutcheon and Lucke [7] found similar factors operating in the case of *Arbacia*.

I am testing this hypothesis by means of experiments, and the results will be published in due course. My detailed studies on the fauna of some of the salt waters of the Salt Range, Punjab, will be published elsewhere.

Leaf-Curl in Cotton and Other Plants

IN a recent communication[1] Mr. Mathur gives an account of his observations on the leaf-curl in garden zinnias, caused by *Bemisia gossypiperda* Misra and Lamba, at Dehra Dun. The title of the letter suggests that the virus causing leaf-crinkle in cottons in the Sudan is the same that causes leaf-crinkle in zinnias at Dehra Dun. This certainly has not been established so far.

Leaf-crinkle or leaf-curl is not uncommon in cultivated plants. There are in the Punjab, occurring quite commonly, leaf-curls of potatoes, tomatoes, chillies, cucurbits, etc. In the Punjab, however, so far, no leaf-crinkle on cotton has been found associated with *B. gossypiperda*. Just now there is scarcely a cotton leaf which is free from white-fly infestation, yet leaf-crinkle is completely absent.

Leaf-crinkle in cotton should not be confused with leaf-crinkle in other plants without obtaining definite evidence that the same virus is responsible for the disease.

Some Characteristics of Ultimate Lines

1. *Classification and Exciting Potentials.*—The ultimate lines are classified as primary, secondary, or tertiary as suggested by Russell, modifying the nomenclature in the form proposed by Catalan and by us.[1]

The following table gives the number of ultimate lines for the different classes and the minimum and maximum values of their exciting potentials. Those computational data are based on the table of the author published in Twyman and Smith's book.[2] A complete list of the exciting potentials and other data for each element will be published shortly in the "Contribución al Estudio de las Ciencias, Serie Mat.-Fisica" (La Plata).

Classification.	Number of Lines.	Exciting Potentials.
Arc lines Primary .	277	0·0 to 1·32
,, Secondary .	206	0·28 to 5·45
,, Tertiary .	53	0·92 to 9·15
Spark lines Primary .	170	0·0 to 0·56
,, Secondary	109	0·14 to 11·90
,, Tertiary .	60	0·32 to 17·94
Not classified . .	204	?
Total number .	1079	

Fifty per cent of the ultimate arc lines correspond to the primary lines class, and the same proportion is maintained in the spark lines. According to Meggers, Kiess, and Walters, jr.,[3] all the ultimate lines of the spark, with no exception whatsoever, are originated in the fundamental levels; this conclusion is also maintained by Catalan.[4] Our computations do not support that assertion, which is only found true regarding very few elements of the iron group.

2. *Absorption.*—Supplementing our observations regarding the ultimate lines [5] we have established, as the extreme limit for the appearance of the ultimate lines in absorption, the value $N_1/N = 1/14{,}500$, that—according to the equation $N_1/N = e^{-\frac{E}{RT}}$, where N_1 is the number of the excited atoms and N the total number of atoms—corresponds to a value of $E = 1{\cdot}03$ volts for $T = 1250°$ and to a value of $E = 2{\cdot}06$ for $T = 2500°$.

The value $N_1/N = 1/14{,}500$, adopted by us, corresponds to an extreme limit because, according to our experimental data,[6] faint absorption lines only are observed for $N_1/N \geqslant 1/1600$ and lines of medium intensity for $N_1/N \geqslant 1/210$; for the value adopted, only lines of absorption of a very faint intensity and few in number are observed. In accordance with the preceding considerations, and not taking into account other factors in the obtaining of the absorption spectra—the most important of which is the vapour tension of the element considered—it is possible to observe, in an absorption at a temperature of 1250°, those lines the original levels of which are the fundamental ones that are separated from it by not more than 1·03 volts; that is to say, 330 lines out of 536, and, at a temperature of 2500°, 414 lines out of 536. The quantities given are maxima, because if we consider the possible number of lines of absorption of medium intensity, the value N_1/N should be 1/210, corresponding to a value of 1·13 volts at 2500°, which shows that—excluding the lines originated at the fundamental levels—only a small number of those corresponding to other levels may be observed in absorption.

3. *Multiplets.*—In the case of multiplets, the ultimate lines fulfil the conditions $\Delta l = 1$ for $\Delta j = 1$ and 0, and $\Delta l = 0$ for $\Delta j = -1$ and 0. The only exceptions to this rule are the multiplets *SP* (Mn, Cr, etc.). This conclusion is identical with the one we established [7] regarding the lines t. fulfil the same con quantum numbers.

Magnetic Analysis of Molecular Orienta in Crystals

By correlating the magnetic constants of a dian netic crystal with those of the individual molecu constituting it, calculated from measurements on the magnetic double refraction of the substance in the liquid state, or from other considerations, it is possible to obtain direct information regarding the orientations of the molecules in the crystal. In a paper which is in course of publication, the results of some magnetic measurements by Mr. S. Banerjee and me on a number of organic crystals are discussed from this point of view.

It is found that in favourable crystals it is possible by the above method to locate the precise molecular orientations. The cases of biphenyl and dibenzyl may be quoted here as examples. Both of them crystallise in the monoclinic prismatic class, in the space group C^5_{2h}. There are two molecules in their unit cells. Their orientations determined from the magnetic measurements are as follows. Let us for brevity define the directions of the lines joining the carbon atoms 4 and 1 in the molecule (in the usual notation), or the atoms 1′ and 4′, as the length of the molecule, and the plane of the benzene rings as the molecular plane. We then find that the lengths of both the molecules in the unit cell lie in the (010) plane in the obtuse angle β, their inclination to the c axis being 20·1° in biphenyl and 83·9° in dibenzyl. As regards the molecular planes, in either crystal, one half of the molecules have their planes inclined at + 59° to the (010) plane and the other half at − 59° to it.

In the case of dibenzyl, sufficient X-ray data are not available to enable us to test the above conclusions. Our results for biphenyl, however, are fully confirmed by the recent X-ray measurements of Dhar,[1] whose values for the above angular parameters are 20° and 58° respectively, which are almost the same as our values.

Formaldehyde in Rain Water

SINCE 1864, when Baeyer stated his formaldehyde hypothesis, numerous attempts have been made to obtain formaldehyde *in vitro* from carbon dioxide and water on exposure to light. Usher and Priestley,[1] Baly, Heilbron and Barker,[2] Dhar and co-workers,[3] Mezzadroli and collaborators,[4] and others, obtained evidence of formaldehyde formation from carbonic acid or bicarbonates in presence or absence of catalysts when exposed to light. On the other hand, Spoehr,[5] Baur and Rebman,[6] Potter and Ramsperger,[7] Bell,[8] Emerson,[9] Zschiele,[10] and Mackinney [11] obtained negative results, although the last-named worker made the following statement: "The status of this problem is extraordinarily involved, though it can be

...ucceeded in obtain-
...cently, Baly and co-
...heir earlier results.
...tion of formaldehyde is
...ions of short wave-lengths,
...nsity is absolutely essential,
...is field could not obtain form-
...he low light intensity used. In
...tion, Dhar and Atma Ram[13] have
...n larger yields of formaldehyde by
...ion of carbonic acid and bicarbonates
magnesium, cerium, etc.
...nown that carbonic acid and water vapour
...e atmosphere, and under the influence of
...t light from the sun, they should combine
...n formaldehyde and oxygen. Hence it seems
...ble that formaldehyde should be present in the
...osphere.

...f appreciable amounts of formaldehyde were present in the atmosphere, it should be partially washed down with rain water. In the last few months, in order to test whether formaldehyde occurs in rain water, we have analysed numerous samples of freshly collected rain water obtained at Allahabad, Barlowganj (Mussorie)—altitude 5500 ft.—and at a village about three hundred miles from Allahabad. In all cases, we have got immediate and definite evidence of the existence of formaldehyde in both distilled and undistilled rain water, as tested by Schiff's reagent, Schryver's reagent, and by the reduction of ammoniacal silver nitrate.

From our experiments, we are of opinion that formaldehyde is actually present in rain water collected in these parts, and it is washed down from the atmosphere. In view of the fact that it is always present in rain water collected in a city, a village, and at a place of high altitude and far from human habitation, it appears that the formaldehyde present in the atmosphere is obtained from the combination of carbon dioxide and water vapour in the presence of the solar ultra-violet light, and not from the decomposition of substances of vegetable origin on exposure to light.[14] It will be interesting to note here that, several years ago, Henriet[15] reported the presence of formaldehyde in air but was not supported by Gautier.

Moreover, in a recent communication,[16] it has been shown from spectroscopic evidence that formaldehyde, like cyanogen, may be present in the absorbing atmosphere of the sun. It will be highly interesting if workers in other countries can also detect formaldehyde in rain water, and I would direct their attention to this matter. Formaldehyde present in the atmosphere and rain water even in small quantities serves as a ready-made plant food and stimulant,[17] and as an antiseptic which can purify the air and act as a disinfectant for the soil.

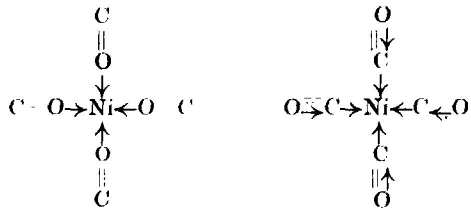
Electric Dipole Moment of Nickel Carbonyl

WE have recently determined the total and the electron polarisations (the latter as the molecular refractivity for the mercury green line 5461) of nickel carbonyl in carbon tetrachloride solution at 0° C., and found values of 39·5 c.c. and 37·3 c.c. respectively. The latter value is somewhat higher than that of 35·5 c.c. calculated from the data of Mond and Nasini,[1] who used the pure substance, for the thallium line 5351, but it is probably not in error by more than $\pm 0 \cdot 1$ c.c., and the difference may be attributed to the difference of concentration. The apparent orientation polarisation of 2·2 c.c. would give the maximum possible value of the electric dipole moment as $0 \cdot 3 \times 10^{-18}$ e.s.u., but since it is of the order which would be expected for the atom polarisation of such a molecule, the moment may be taken to be zero with a high degree of probability.

This result shows that the structure must be symmetrical, and therefore cannot be cyclic, as suggested by Sugden,[2] nor can the structure be as shown in formula (*a*), in which co-ordinate links are formed



(*a*) (*b*)

between doubly bound oxygen atoms and the central nickel atom, for in this the co-ordinate link and the double bond on each oxygen atom would, on the tetrahedral atomic model, not be collinear, so that by partial rotation about the former links the molecule would become unsymmetrical and, like the methyl and ethyl orthocarbonic esters (electric dipole moments 0·8 and 1·1 respectively),[3] would have a finite moment.

The only structure which could be symmetrical is that shown in formula (*b*), or a similar one with the co-ordinate links between oxygen and nickel. This, which is derived from the co-ordinate triple link structure for carbon monoxide suggested by Langmuir and discussed by Hammick, New, Sidgwick, and Sutton,[4] would be symmetrical if the co-ordinate links, which must be collinear with the triple bonds, were directed either along the axes of a regular tetrahedron or to the corners of a square. It is more likely that the co-ordinate links to the nickel atoms would be formed by the acceptor carbon atoms than by the donor oxygen atoms, and so the former of the structural isomers here possible is the more probable. In either, the third quantum group of the nickel atom is completely filled with unshared electrons, and the valency group is a fully shared octet: such a structure is in complete accord with the diamagnetic nature of the substance.[5] Since no *d* electrons are utilised in attaching the CO radicals, it follows from Pauling's theory[6] that the tetrahedral arrangement is far more probable than the planar one.

The classical hypothesis that a triple bond and a single one on the same atom are collinear has been attacked by Bergmann,[7] who cites electric dipole moment evidence against it, but his arguments are not convincing. It has been given theoretical support by Pauling,[6] and has been proved correct experimentally for the cases of acetylene and hydrogen cyanide,[8, 9] by examination of the spectra, which show that the molecules are rectilinear.

This result is further support for the co-ordinate triple link structure ascribed to the other divalent carbon compounds, the *iso*-cyanides.

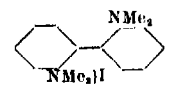
Stereochemistry of Diphenyl

THE stereochemistry of diphenyl, as was shown in the "Research Items" in NATURE for April 2, p. 512, in reference to a paper by Prof. R. Kuhn, continues to produce problems of great interest. At a meeting of the Chemical Society held on May 5, a new 'dynamic' effect of groups in the 2:2′ positions was described.[1] We have now effected the optical resolution of the monomethiodide of 2:2′-bisdimethylaminodiphenyl:



The *d*- and *l*-methiodides have $[\alpha]^{20°}_{5791} \pm 48°$ in aqueous solution, in which ionisation is complete, and cold solutions retain their activity for indefinite periods. In aqueous solution at 100°, half-racemisation occurs in just over two hours.

The dissymmetry of the methiodide molecule can only be due to the dynamic effect of the three methyl radicals attached to the nitrogen atom, which, it should be noted, is the smallest atom possessing a tetrahedral configuration. The various implications of our results are being investigated.

The Ring System of Sterols and Bile Acids

THE constitutional formula tentatively suggested by Butenandt[1] for the hydrocarbon $C_{18}H_{14}$ obtained by him from ketohydroxy-œstrin (follicular hormone) is closely related to the new constitutional formula of sterols and bile acids previously advanced by Rosenheim and King.[2] The applicability of this formula to the basic ring system of ketohydroxy-œstrin and pregnandiol (see Bernal[3]) was, indeed, expressed in our preliminary note, and the work of Marrian and Haslewood[4] and that of Butenandt (see above) supplies welcome experimental evidence in its favour.

It may be recalled that the essential principle of the formula proposed by ourselves consists in the grouping of three six-membered rings (I., II., and III.) as in phenanthrene, an arrangement which at once permits of a straightforward formulation of those experimental facts, for which the hitherto accepted formula (Windaus-Wieland) afforded no adequate explanation. Chrysene formation from such a ring system can obviously take pla is six- or five-memb of the adjoining CH_3

In the circumstances Dr. Butenandt to refer, fo posed ring system, to papers which are still "in the press authors will be found to prefer formula with a five-membered latest available publication from tory[5] our formula with a six-memb adopted.

Hall Effect in Beryllium

I HAVE recently carried out work on the Hall effect in beryllium, by using a plate measuring 1·5 cm. × 1·5 cm. × 0·045 cm., which was prepared, for this purpose, by Siemens and Halske of Berlin, from a sample of pure beryllium (99·5 per cent). I made use of Hall's classical experimental arrangement, and measured the e.m.f. by means of a potentiometric method with the use of a very sensitive Siemens and Halske's "Pancergalvanometer".

A large Weiss-type water-cooled magnet (made by Max Hohl of Chemnitz) capable of producing field strengths up to 27,500 gauss in a 4 mm. gap, the pole faces being 15 mm. in diameter, was used.

Many measurements were taken by varying the intensity of the current, and that of the magnetic field up to a maximum of 500 milliamperes and 27,500 gauss respectively.

The effect was very small and positive; the value of the Hall coefficient was found to be $+0·0024 \pm 0·0001$.

A detailed account of the experiments will be published shortly.

Absorption of Boron Neutrons by Lead

WHILE examining the absorption of neutrons emitted from boron bombarded by α-rays from an ampoule of radium emanation, we have been able to establish a phenomenon which seems worthy of attention.

The absorption of beryllium neutrons by lead is greater than by an equal thickness of copper or paraffin. Boron neutrons appear to possess less energy than beryllium neutrons, and are more absorbed by copper and paraffin wax than by lead. To the neutrons from boron, lead is very transparent, a screen 5 cm. thick showing scarcely any appreciable absorption, as shown by the number of recoil nuclei.

During a discussion at the International Electrical Congress recently held at Paris, Prof. Fermi put forward the suggestion that this phenomenon can be approached along the lines of the Ramsauer effect, the wave-length, h/mv, of the neutrons possibly being of the same order as that of the effective radius of a nucleus.

Research Items

...illes (Dordogne).—Exca... caves in the neighbour... village on the banks of the ... west of Périgueux, have been ... Peyrony (*Mém.* 10, *Arch. Inst.* ...ne). The Grotte des Bernous ...sterian, followed immediately by ...ian, Lower Aurignacian being absent. ...aposition, and in some instances inter- ...Mousterian and Aurignacian suggests that ...usterian survived while Lower Aurignacian ... elsewhere, and was driven out by Middle ...cian tribes. The Fourneau du Diable fur- ...d a stratification of Aurignacian, Solutrean, and ...istat, while on the terraces lying above there were ...ree horizons of Solutrean. Many objects found were ...nique, such, for example, as a haft of reindeer horn socketed to take a stone implement, and a collection of coloured pebbles arranged in a quadrilateral figure. The latter, it is suggested, may have been fastened to some material, such as wood or leather, which has perished, and have been used as a dance rattle. The cultures of Bourdeilles throw new light on a number of questions. The development of the flint industry of the Solutrean can here be followed in detail and the first appearance observed of the implements, such as daggers and the *feuille de saule*, which were the forerunners of the weapons of neolithic times. From the evidence at Bourdeilles it is concluded that for a long time different peoples lived side by side and finally coalesced to adopt a single culture. This view is borne out by the occurrence, in what is virtually the same cultural horizon, of Chancelade man with his Eskimo characters and the man of Laugerie Basse, a Nordic type.

Moieties of the North-Western Mono, California.—In a study of the north-western Mono in the vicinity of Northfork, an affluent of the San Joaquin River (*Univ. Cal. Pub. Amer. Arch. Eth.*, vol. 31, No. 2), Mr. E. W. Gifford records that these people are divided into two moieties, which function in feasts, ceremonies, and games in reciprocity and in rivalry. Thus, at ceremonies or feasts, each moiety prepared food for the opposite moiety; but the moieties never ate together. At these feasts the children ate with the father; but the wife did not eat with her husband if she belonged to the other moiety. One moiety prepared and burned the dead of the other moiety, a service for which they received payment. At the mourning ceremony, which took place two years afterwards, they sang for and washed the mourners, fed them, and paid them. After the ceremony the mourners reciprocated with payment and a feast. The totemic animals, birds, were connected with the moieties, and not with the four divisions, of which two were assigned to each moiety. An individual, however, might consider all totems of his moiety as his own; but the golden eagle, although it was a totem of one of the moieties, was reverenced by everyone as the creator as well as the chief of the birds. If a man wished to kill his totem for its feathers, he explained matters to it, pointing out that it would not die, as he would take care of its feathers. If an eagle was killed by one of the vulture moiety, he brought the feathers to the eagle chief and paid for them. Each moiety had shamans. A vulture shaman who killed an eagle man by magic was killed by the eagle chief unless he had previously paid the eagle chief for the privilege.

Vocational Tests of Dexterity.—Vocational tests of ...ility are classified and psychologically estimated ...lie E. Weiss Long and Prof. T. H. Pear in Report No. 64 of the Industrial Health Research Board. English, American, French, and German publications are mentioned, and special prominence is given to the less familiar work of foreign countries, illustrations of test methods being drawn from them. The report opens with a discussion of 'skill' and the definition of it as "the integration of well-adjusted muscular performances". Thus understood, it needs a complex system of testing. Vocational research should concentrate on the specific psychological requirements of an occupation, and on determining the most appropriate tests for discovering whether, and in what degree, given individuals possess them. Hence, claims made for single tests in different countries cannot be substantiated. In selecting for an occupation demanding a fairly complex performance, it is of importance to use series of tests involving complex activities. The individual tests should be as numerous and diverse as possible, and the time allowed to do them should be fully adequate. It is not important that the single functions called into play should be identical with those required industrially. This comprehensive survey shows that less has been indisputably established than the vocational guidance promoters would like to think: but it also affords an excellent guide both to the available material and future lines of research.

Adaptation of Sand Reptiles to Environment.—In the Sahara and on the sandy plains of California, Walter Mosaner has been struck by the remarkable resemblances between the sand-inhabiting reptiles (*Copeia*, p. 72, 1932). These are not adaptations to desert conditions, which tend rather to affect behaviour, but structural changes due to the mechanical characteristics of the sand and the texture of the substratum. The changes are twofold: some are modifications facilitating locomotion on or in the sand, others serve for the protection of the sense organs and body openings. As some sand-dwelling mammals have adopted occasional bipedal locomotion, so many lizards assume a bipedal position when at top speed. The tracks in the sand show how different is the work accomplished by fore and hind feet, and with increasing speed the difference is accentuated until the fore-feet, and the tail also, are held clear of the ground. A curious locomotor adaptation common to Saharan and Californian snakes is the habit of 'side-winding', and many structural features, such as the stream-lined body, shovel-like snout, countersunk lower jaw and degenerate limbs, are associated with the habit of burrowing in the sand. Although perhaps less markedly, the protection of the eyes by fringe-like scales, of the tympanic membrane by overlapping scales, and of the slit-like nostril (in *Phyllorhynchus*) by the projecting edges of the nasal scales, all seem to be associated with the burrowing habit.

Copepods of Chesapeake Bay.—The peculiar conditions of Chesapeake Bay offer excellent opportunities for a detailed study of copepods, since in many cases they have a wide distribution and accommodate themselves to great and fairly rapid changes in salinity. Dr. C. B. Wilson shows ("The Copepod Crustaceans of Chesapeake Bay", by Charles Branch Wilson; No. 2915, *Proc. U.S. Nat. Mus.*, vol 80, Art. 15, 1932) that *Acartia clausi* is the most frequently occurring copepod in the Bay, next to it coming *A. longiremis*. These two species are largely eaten by the shad, and are of much greater economic importance than was previously realised. In March, when copepods are at their maximum, the largest hauls are made up almost

entirely of these two species, which breed twice a year, in winter and in summer. The March maximum is the product of the winter breeding, the young copepods having exceptionally good opportunities for growth, as there is then a relative scarcity of fishes and other animals which prey upon them. Later on, the numbers diminish rapidly, probably owing to the coming of the shad. The author finds four breeding seasons in Chesapeake Bay, in winter, spring, summer, and autumn, each characterised by several copepods bearing eggs. In the months following, nauplii and young are caught in numbers. Each copepod has one or two breeding seasons. The records indicate that water of higher salinity is more favourable to the breeding than the low salinity water at the inner end of the Bay.

Fauna of the Tay Estuary.—A study of the inhabitants of the Tay Estuary, made by W. B. Alexander for comparison with the corresponding fauna of the River Tees, reveals the different capacities of marine animals to penetrate upstream into the region of brackish and even fresh water (*Trans. Perthshire Soc. Nat. Hist.*, vol. 9, 1932, p. 35). The real marine fauna, characterised by the presence of limpets and common star-fishes and red sea-anemones, may be said to end near the Tayside Lighthouses. Two miles farther up the estuary, at the Tay Bridge, these have dropped out, and here periwinkles, the amphipod *Orchestia littorea*, three species of the sea-worm, *Nereis*, and a few others reach their limit. Beyond this, for ten miles farther, the shore-crab and some smaller crustaceans, the polyzoon, *Membranipora*, *Nereis diversicolor*, and the seaweeds, *Ulva* and the common bladder-wrack, penetrate. But here ends the conquest of marine forms over the influence of fresh water, and only two species of crustaceans, *Neomysis vulgaris* and *Corophium longicorne*, are found five miles farther on, at Newburgh, although adventurous flounders live in association with a fresh-water fauna twenty miles beyond the limit of the real marine fauna.

Hosts of Rust Fungi.—" Inoculation Experiments with some Heterœcious Species of the Melampsoraceæ in Japan ", by N. Hiratsuka (*Jap. J. Bot.*, vol. 6, No. 1, pp. 11-34 ; 1932), gives the results of very extensive inoculation experiments with the teleutospores and æcidia of heterœcious Melampsoraceæ. The interest is mostly local, but a well-defined specificity of the fungus *Melampsora larici-epitea* claims more general notice. Teleutospores from *Salix viminalis* v. *yezoensis*, *S. rorida*, and *S. sachalinensis* will all infect *Larix Kaemferi* and produce æcidia thereon, but æcidia from the three different sources will not interinfect the three species of *Salix*.

Petrogenesis of the Dartmoor Granites.—Many intensive studies of reaction between granite and country rock have been made during recent years by British geologists, but by far the most exhaustive is that carried out with brilliant success by Dr. A. Brammall in collaboration with Dr. H. F. Harwood on the Dartmoor granites (*Quart. J. Geol. Soc.*, **88**, pp. 171-237 ; 1932). The long-awaited record of this model of petrogenetic research, including, as it does, more than eighty detailed analyses of carefully selected series of rocks and minerals, constitutes an unrivalled storehouse of petrological and geochemical data and embodies a convincing discussion of the bearing of these data on many problems, hitherto elusive, of rock genesis. It is demonstrated beyond any possibility of doubt that the observed variation of rock-types cannot be the result of differentiation alone. The study of inclusions and contact-facies shows that an initial acid magma was basified and enriched in biotite and certain other minerals by reaction with the shales, diabases, and spilites of the invaded country r tion of xenoliths i ranging between types biotite-granite. It is c semblage of rock-types c for by the operation of a bi- tion and differentiation pr during the emplacement of the is impossible in a brief paragra direct attention to the quality and outstanding investigation. Both a order, and the authors are to be congra great achievement.

Coral Reefs and Raised Beaches of Japa not appear to be generally known that ree corals flourish in some parts of the Japane H. Yabe and T. Sugiyama (*Sci. Rep. Tôhoku Univ.*, Sendai, ser. 2, vol. 15, No. 2, 1932, p. 143) s that the more southerly islands (Riukiu, Ogasawar and Taiwan) have well-developed fringing reefs and bank barriers, with a breadth varying from 150 metres to 4000 metres. 202 species and varieties of corals have been recognised, a larger number than is found in either the Philippine or the Hawaiian Islands. Around the more northerly islands (Kiushû, Shikoku, and Honshû), owing to the influence of the warm current, reef corals thrive so far north as lat. 35° N. but do not form well-developed reefs. A living representative of *Stylocœnia*, a genus hitherto known only in the fossil state, has been found. Farther north, in the Kwantô region, raised beaches have been found at levels ranging from 4 metres to 20 metres above sea-level. S. Nomura (*ibid.*, p. 65) gives a list of 470 species of Mollusca found in these beaches. The majority of the species still live along the coasts of central Japan, but some only in western Japan or farther south. The raised beaches are regarded as of Neolithic and later date.

Upper Atmospheric Ionisation.—When the frequency of wireless waves incident on the Kennelly-Heaviside layer is being increased, a stage is reached when reflection is replaced by transmission, and the waves pass to the Appleton layer before return ; with further increase in frequency, the same occurs there, but the waves are now completely lost. From the critical frequency for transmission in each case the maximum density of the ions or electrons present can be calculated. The results of some routine measurements of this nature have been described by Prof. E. V. Appleton and Mr. Naismith (*Proc. Roy. Soc.*, July), principally for the lower layer. The ionisation has both annual and diurnal variations, as well as more irregular fluctuations, some at least of which are associated with magnetic storms. During the day, the ionisation is high, with a flat maximum near noon, and it is low at night, again with little change; the ionisation is heavier in summer than in winter. The full interpretation of the results depends on whether molecular and atomic ions or electrons are responsible for the reflection and transmission. If the negative particles are massive, their maximum concentration in the lower layer is about 10^{10} per c.c. in summer, but if they are electrons, the concentrations are only of the order of 10^5 per c.c. A better idea of the significance of the densities may perhaps be obtained from the fact that the number of electrons per c.c. in an Osglim lamp is of the order of 10^{10}, whereas 10^5 per c.c. corresponds more nearly to the state of a gas ionised by X-rays ; the analogy is not, however, complete, because the negative carriers in the Osglim lamp are mainly electrons, and not molecular or atomic ions. Actually it is known from other lines of reasoning that the negative particles in the upper layer

...ver layer at least

...ocity Positive Ions.—...ockcroft and Dr. E. T. S. ...tegration by protons is de- ...of the *Proceedings of the Royal* ...n takes place most readily ...boron and fluorine also give more ...of the number of particles from ...kilovolts, uranium, aluminium, and ...n 1 and 2 per cent, and beryllium, ...alt, nickel, copper, and silver between ...per cent. Oxygen, sodium, potassium, ...lead give very small numbers, and in some ...is not yet certain that the effect is not due ...disintegration of impurities. The disintegra- ...of uranium is of particular interest, in view of ...natural activity, but the artificially produced ...particles appear to have a longer range than the natural ones. Several elements, including beryllium, give two types of particles, presumably with different energies. The majority of the experiments on the properties of the emitted particles have been done with those from lithium. With this element, there can be very little doubt that α-particles are formed, and that they are almost homogeneous in speed, and produced in pairs. From their range, it is calculated that 17 million electron volts of energy are released, in agreement with the 14 ± 3 million electron volts required from the mass defects of the various nuclei involved, but the number of disintegrations taking place is smaller than would be expected from the quantum theory of the effect. In view of the very small chance of protons of 500 kilovolts penetrating the potential barrier of a heavy nucleus in any way other than by resonance, it would appear probable that this is the process coming into operation. It is noteworthy that the three elements—lithium, boron, and fluorine—which give the largest emission of particles also show a similar change in emission with increase in the speed of the incident protons. These elements are all of the $4n+3$ nuclear type, with nuclei presumably made up of α-particles with the addition of three protons and two electrons, so that it is reasonable to suppose that capture of a proton may lead to the formation of a new α-particle inside the nucleus.

Neon Isotopes.—By the aid of a new diffusion process, Prof. G. Hertz has now effected a practically complete separation of the lighter isotope of neon (*Naturwiss.*, June 24). The process is an elaboration of the principle of differential diffusion through porous tubes, and is carried out in a train of twenty-four interconnected elements, controlled by mercury vapour pumps. A single run of eight hours, starting from ordinary neon with a 10 : 1 isotope ratio, gave either a mixture with a 10 : 8 ratio or one with only about one per cent of the heavy isotope. The experiments were controlled by a mass-spectrograph, and by study of the fine structure of the neon spectrum with an interferometer. Evidence was obtained by the former method that there is a fourth isotope of neon with mass 23, in addition to the common pair with masses 20 and 22, and the rarer isotope of mass 21.

Astronomical Topics

Astronomical Notes for September.—Mercury is in elongation as a morning star on Sept. 3; 18° from the sun. Venus is in elongation as a morning star on Sept. 8; 46° from the sun. Being north of the sun, it is well placed for observation.

There is an almost total eclipse of the moon (magnitude 0·982) on the evening of Sept. 14. The moon enters the umbra at $7^h\ 18^m$, and leaves it at $10^h\ 43^m$, the maximum eclipse being at $9^h\ 0^m$. The sun sets in London at $6^h\ 18^m$. Study should be made of the brightness and colour of the eclipsed region.

There is only one occultation visible in London at a convenient hour; 27 Capricorni disappears at $6^h\ 44^m$ on the evening of Sept. 11.

Saturn passed opposition in July, but is still observable, though low down. Uranus is observable in Pisces; it reaches opposition in mid-October. A map of its track among the stars is given in the B.A.A. Handbook for 1932.

The comet Peltier-Whipple was visible with an opera-glass in August, and should still be an easy telescopic object in September. The following ephemeris for 0^h is from the Whipple-Cunningham orbit:

		R.A.			N. Decl.	
Sept.	2	9h	57m	36s	79°	47′
	6	11	44	44	76	22
	10	12	35	45	72	12
	14	13	3	14	68	16
	18	13	20	12	64	48
	22	13	31	56	61	46
	26	13	40	32	59	7
	30	13	47	16	56	46
Oct.	4	13	52	48	54	45
	8	13	57	28	52	56
	12	14	1	40	51	22

The comets Newman and Borrelly need more powerful instruments; an ephemeris for Newman is given in the *Observatory* for August and September; ...orrelly, use the B.A.A. Handbook, applying the ...iven there for perihelion one day later than the assumed value. The Handbook also gives a search ephemeris for Tempel's comet, 1866 I; all astronomers who have suitable means are asked to join in the search for this comet. Its detection would enable the past history of both the comet and the Leonid meteors to be placed on a firmer footing.

The sun crosses the equator and autumn begins at $6^h\ 24^m$ on the morning of Sept. 23.

Add 1^h to all times given, to reduce to Summer Time.

The Welsh Meteor of April 14, 1931.—Loud explosive sounds were heard over North Wales on the morning of April 14, 1931. Some of the daily papers described it as an earthquake; Mr. B. M. Peek, who was on the mountain Moel Siabod, sent an article to the British Astronomical Association, in which he made the conjecture that the sounds were due to the passage of a large meteor which probably fell in the Irish Sea. The *B.A.A. Journal* for June 1932 has another article about it, by Mr. A. King. His researches have placed the meteoric character of the object beyond doubt; two observers, in Ripon and Leeds, actually saw the meteor; many people in Yorkshire heard the sounds, which some took for thunder; moreover a fragment of the meteor was seen to fall at Coch-y Bug Farm, a few miles south of Carnarvon. Dr. Spencer has seen this fragment, and pronounces it to be a genuine meteorite, "apparently of an unusual type". Mr. King has investigated the real path of the meteor; the calculated earth-point is some eighteen miles west of the farm where the fragment fell; the visible path appears to have begun over Bakewell and ended over Mold. The velocity was not much less than parabolic, the radiant being 177° from the apex, so that the meteor was overtaking the earth. It is satisfactory that it has been possible to determine so much about this interesting meteor. From the loudness of the sounds it is conjectured that by far the largest portion of the meteor fell in the sea.

The Total Solar Eclipse of Aug. 31

AN account of the work which is being undertaken in connexion with the total solar eclipse of Aug. 31 by the three British expeditions in Canada under the auspices of the Joint Permanent Eclipse Committee of the Royal Society and the Royal Astronomical Society appeared in NATURE of July 23, p. 116.

The Imperial College expedition to Montreal will be located on the roof of the Molson Hall of the Arts Building of McGill University, where Prof. Ira Mackay has kindly placed every facility at the disposal of the observers. The site will afford a good view of the sun, the intervening ground being occupied mainly by a reservoir and the wooded slopes of Mount Royal, so that a very steady image of the sun should be obtained. An excellent dark room and source of electric current are convenient of access. The observations are in charge of Prof. H. Dingle, who will be assisted by members of the McGill University staff and students. Through the kindness of Prof. A. S. Eve, the resources of the Macdonald Physics Laboratory and workshops have been made available to the observers, and if the weather is favourable there is every prospect that the expedition will be as successful as the nature of the programme allows.

Two problems are to be attacked. First, the photography, with large dispersion (about 0·7 A. per mm.) of the bright-line spectrum at the cusp of the partially eclipsed sun, which was observed visually by Prof. A. Fowler at South Kensington in 1912. Owing to the extremely short length of slit which will be illuminated (a small portion of a millimetre up to a few minutes before totality with the 2-inch solar image which is to be used), the possibility of success in this part of the programme is somewhat speculative. Provision, however, has been made for both rotatory and translational motions of the sun's image in immediate obedience to the desires of an observer watching the slit through a small telescope, and strong hopes are entertained of a successful issue. The second problem is the photography, with the same dispersion, of the Fraunhofer spectrum at the limb of the sun just before and after totality, in order to obtain precise wave-lengths of the limb-light free from atmospherically diffused disc-light, which is unavoidable during full sunshine.

The intense interest which the eclipse is arousing in America is evidenced by an extensive series of bulletins issued by Science Service, of Washington, D.C. They are divided into two parts: first, information on the nature of eclipses in general, their history, and methods of predicting them; secondly, the arrangements on the present occasion, the locations and plans of the various parties. Thus we note that this will be the ninth totality observed by Dr. S. A. Mitchell, of Leander McCormick Observatory, who will use at Magog the large concave gratings that he used at Tin Can Island in 1930 to study the height of different gases in the solar atmosphere. The Franklin Institute will photograph the corona with a camera 85 feet long, recalling the long refracting telescopes of pre-achromatic days. The Georgetown party, under Dr. P. A. McNally, *S.J.*, will take photographs to measure the Einstein shift of stars; the star-field is not, however, very suitable, and totality is rather short for the purpose; the party will also investigate the infra-red spectrum of the corona. The astronomical artist, Mr. H. R. Butler, has made long journeys to paint total eclipses, but on this occasion he will enjoy 93 seconds of totality at his own home. Mount Washington, which is 6288 feet high and the highest point in the path of totality, will be occupied by a Science Service party, who will endeavour to take photographs of the moon's shadow on the gro photographs. Astronomica been a special feature of the Angelus, Michigan; a party motion films during totality.

The U.S. Naval Observatory will time signals from 1.55 to 2.0 P.M. an 4.0 P.M. Eastern Standard Time on Au progress of the eclipse will be describe to those outside the track.

The effect of the eclipse on radio observat be investigated. The distinction between the eclipse and the eclipse of the corpuscular strean discussed by Profs. S. Chapman and E. V. Apple in a letter in NATURE of May 21, p. 757. The Fren and Dutch Polar Year parties will be near the centre line of the optical eclipse, and will make special observations on layer heights. The British party at Tromsö will be near the sunset limit, as will stations in south-east England. The Tromsö workers will, however, measure the densities of ionisation at the time of the eclipse, with control observations on adjacent days, and corresponding measurements will be made at King's College, London, the Radio Research Station, Slough, and at the Cavendish Laboratory, Cambridge. Special observations on trans-Atlantic signals will be made at Slough and at Post Office stations, with special regard to the fact that the particle eclipse may be total over nearly the whole width of the Atlantic at once.

Parties from the U.S. Bureau of Standards, Washington, under the direction of Dr. J. H. Dellinger, will record eclipse effects on the field strengths of radio waves and on the heights of the ionised layers.

Through the Associate Committee on Radio Research of the National Research Council of Canada, three Canadian parties will also undertake radio observations. An effort is to be made to investigate the variations of the Heaviside layers during the passage of the shadow, and to test the theory advanced by Prof. S. Chapman, that the Appleton layer is ionised by ultra-violet light and the Kennelly-Heaviside layer by a stream of corpuscles or of neutral particles.

One party, under the direction of Lieut.-Col. Steel and Dr. Rose, of the National Research Laboratories, Ottawa, is to investigate the upper layer from a point in Kingston, Ontario. Another party, under the direction of Prof. A. S. Eve, of McGill University, and consisting of Messrs. Ross and Stadler, is proceeding to Corner Brook, Newfoundland, to study the 'corpuscular eclipse', which it is calculated will take place to the east of the optical shadow band. A third party, under the same direction and consisting of Messrs. Henderson and Smythe, is proceeding to Vankleek Hill, south-west of the Ottawa River and below the city of Ottawa, to take observations on the Kennelly-Heaviside layer, with the object of determining the ultra-violet light effect. Both Vankleek Hill and Kingston are to the west of the optical shadow band on the surface of the earth.

The Canadian Marconi Company and Northern Electric Company are co-operating with the National Research Council in these investigations. The former will take continuous field strength measurements in the short-wave band, while the latter will take similar measurements at broadcast frequencies. The results of their measurements will check the information obtained by the other parties.

During the eclipse, Messrs. Laurence and Howlett of the National Research Laboratories hope to vestigate the origin and appearance of shadow

he Deterioration of Paper on Ageing

nence, future generations of members may
the efforts of their predecessors have been

e problem is one of recent origin, for it is only
e 1860, 1870, and 1880 respectively that esparto
ass, mechanical wood pulp, and chemical wood pulp
have been used in paper-making. Prior to 1860, rags (that is, cotton, flax, and hemp) were the usual raw materials, and although excessive loading, bleaching, or alum may shorten the life of rag papers, they are generally recognised as being the most permanent. This fact was, indeed, recognised so far back as 1898 in a Report to the Royal Society of Arts, in which it was stated that esparto and straw papers are more permanent than mechanical pulp papers, but less permanent than chemical pulp papers. It was therefore specified that permanent book papers should contain less than ten per cent of loading and not less than seventy per cent of rag.

Subsequent work in the United States and in Germany has modified the inferences drawn from this Report, since it has been shown that the method of manufacture of the paper and the conditions of storage are equal in importance to the nature of the fibre in determining how long the paper will last. Bulletin No. 2795 (1912) of the American Newspaper Publishers' Association, for example, points out that excessive dryness (resulting from the artificial heating of libraries) and excessive dampness may alter the normal moisture content of the paper, and so stimulate its deterioration. Cases are on record in which a badly-made rag paper had undergone rapid deterioration, whilst at the other extreme hand-made mechanical wood-pulp has been stored under proper conditions for a hundred years and still shows no sign of ageing.

A Committee of the League of Nations also pronounced in favour of unbleached rag papers in 1928, and quite recently the investigation has been taken up by the Bureau of Standards in the United States (*Miscellaneous Publication* No. 128, *Research Papers* Nos. 349 and 352). Not only have opinions been expressed as to storage conditions, but in addition, what appears at first sight to be a revolutionary recommendation is made, namely, that the paper may be prepared from any fibres except those of unbleached or mechanical wood-pulps. The great difficulty in arriving at trustworthy results is due, of course, to the impossibility of carrying out tests under the conditions of practice. Not only would this take too long, but it must also be remembered that the earliest commercial papers made from wood or esparto are not more than seventy-five years old, and, moreover, that the extensive improvements in manufacturing methods in the meantime have resulted in a corresponding improvement in the paper of to-day. The Bureau of Standards and others have therefore had to resort to accelerated ageing tests, the actual technique of which varies from one investigator to another and may involve heating for seventy-two hours at 40° to 100° C., with or without exposure to sunlight or ultra-violet rays.

B. L. Wehmhoff, who as technical director of the Government Printing Office at Washington must be regarded as an authority on such matters, has recently devoted some attention to them in a paper before the Technical Section of the Pulp and Paper Industry (*Proceedings*, **94**, 57; 1932). The paper is of value not so much as an account of original work, but because the author has collected the personal opinions of a number of paper experts all over the world on the value of accelerated ageing tests.

The opinions differ widely, but there seems to be general agreement that a temperature of 100° C. corresponds with rather drastic treatment, and, moreover, that the type of deterioration produced by heat and light is not necessarily the same as that which occurs on storage. Opinions also differ as to the value of chemical tests as a means of determining the permanence of paper. This applies particularly to the α-cellulose value, for all agree that the copper number, rosin content, and acidity (or pH value) should be as low as possible. The effects of traces of impurities also require investigation; for example, there is reason to believe that ferrous iron accelerates the deteriorating influence of rosin.

It is not surprising that specifications for the same type of paper proposed by different bodies are by no means identical. A Report on the subject to H.M. Stationery Office is a cautious and balanced statement of the available facts, and few responsible for the purchase of paper will disagree with the opinions expressed. The Report states that there is no evidence that papers made from esparto or chemical wood deteriorate if stored under proper conditions. At the same time, new, clean, white or unbleached rags are preferable for the best papers, and whenever it is a question of choosing between esparto and chemical wood, the former should be rejected. J. G.

Early Man in Algeria

IN the course of a recent note on dental mutilation (see NATURE, Aug. 20, p. 268) reference was made to its occurrence in fossil human remains from Afalou-bou-Rhummel. A communication presented to the first International Congress of Prehistoric and Protohistoric Sciences by MM. Marcellin Boule and Henri Vallois, on "The Fossil Men of Afalou-bou-Rhummel (Algeria)", was welcomed as an authoritative statement on "a new type of fossil man" from North Africa. Prehistoric human skeletal remains have been discovered in North Africa on several occasions, but unfortunately most of them—from the shell-heaps Tunisia and near Constantine as well from certain
n caves—cannot be dated with certainty. The type of Afalou agrees with the type already discovered in Algeria, but the deposits in which previous discoveries have been made are usually regarded as of neolithic age.

The human remains studied in the communication by MM. Boule and Vallois belong to at least fifty individuals; and although they were scattered, nine skeletons have been reconstructed. The cave in which they were found is known by the name of Afalou-bou-Rhummel, and is situated on the Algerian littoral in the commune of Oued Marsa. The cave was excavated in 1928 and 1929 by M. Arambourg with the financial assistance of the Institut de Paléontologie humaine. Both stratigraphical and archæo-

logical evidence point to the dating of the remains as definitely Pleistocene and their cultural horizon as Upper Palæolithic.

The remains are homogeneous in character. The skull is pentagonal, about equal numbers being mesaticephalic or dolichocephalic, and a small number brachycephalic. It is moderately high. Sometimes the occiput tends to be chignon-shaped. The forehead is receding and the supra-orbital arches are united in a well-developed prominence at the glabella. Almost all the skulls have a brutal aspect. The face is short and broad; the nose platyrrhine or, at times, mesorrhine. The orbits are low. There is no prognathism. The bones of the skeleton as a whole are very robust, the muscular attachments strongly marked. Stature is below the mean. Sometimes the upper incisors had been knocked out early in life.

Similar skulls have been obtained from the shell-heap of Mechta el-Arbi near Constantine, notably by MM. Debruge and Florance in 1913, and others have been discovered since that date in excavations by M. Debruge.*

The type of Afalou is new. It bears no resemblance to Neanderthal man or to the Mediterranean or negro types of modern times. It differs from Cro-Magnon and, markedly, from Asselar man (see NATURE, Aug. 20, p. 280) notwithstanding the common cultural feature it shares with the latter in the practice of evulsion of the upper incisors. It is, therefore, proposed that the type should be known as the Mechta race, from the site on which it was first found; and it is to be regarded as associated with the Capsian culture.

* Sir Arthur Keith refers to four skeletons excavated from the kitchen-midden at Mechta el-Arbi by Mr. Alonzo W. Pond in 1927 and described by Dr. Fay-Cooper Cole. Sir Arthur accepts the attribution of the site to the Capsi.n culture. *See* "New Discoveries relating to the Antiquity of Man", London, 1931, pp. 213-214.

University and Educational Intelligence

LONDON.—The following degrees have been conferred: D.Sc. in anatomy on Solly Zuckerman (University College) for a thesis entitled "The Menstrual Cycle of the Primates"; D.Sc. in biochemistry on Margaret A. C. Fixsen (Lister Institute of Preventive Medicine) for a thesis entitled "The Effect of Desiccation on the Nutritive Properties of Egg-white"; D.Sc. in zoology on Norman J. Berrill (University College) for a thesis entitled "Studies in Tunicate Development, Part II. Abbreviation of Development in the Molgulidæ" (*Phil. Trans.*, B, vol. 219); D.Sc. (Engineering) on Charles Edward Larard (Northampton Polytechnic Institute) for published papers on experimental and mathematical investigation dealing with the viscous and elastic straining of ductile material, together with their original work; D.Sc. in metallurgical chemistry on Frank Adcock (private study) for thirteen independent published works, together with two subsidiary contributions; D.Sc. (Engineering) on George A. Tomlinson (private study) for fifteen published papers on (1) atomic forces and cohesion, (2) applications of metrology to engineering problems, together with three subsidiary contributions.

The London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1, has issued a pamphlet detailing the post-graduate courses of instruction in preventive medicine given at the School. These comprise courses of study for the diplomas in public health and in tropical medicine and hygiene, and an advanced course of study for the diploma in bacteriology. A brief synopsis of the course is included in each case.

Calendar of Geographical Exploration

Aug. 31, 1873.—Franz Josef Land

Julius Payer discovered this arctic archipelago. An Austrian polar expedition had been prepared by Count Wilczek, and Payer and Weyprecht in the *Tegetthof* set out in 1872. While the ship was beset by ice, high land was seen to the north-west and later in the season Payer led expeditions to Hochstetter and Wilczek Islands. After a second winter in the ice-bound ship, a difficult journey northwards to Cape Fligely, 82° 5′ N. (Rudolf Land), was made. This remained the highest northern latitude reached until 1859. Mountain ranges indicating land beyond the eighty-third parallel were seen. B. Leigh Smith in 1881–82 explored the whole southern coast from 42° to 54° E., discovering many islands and sounds. In 1894, Alfred Harmsworth fitted out an expedition in the *Windward* under F. G. Jackson, with the object of establishing a base in Franz Josef Land for an attempt on the north pole. In 1896 the Harmsworth-Jackson expedition reached Cape Richthofen and saw a great sea to the north. Nansen, on his southward journey, approached Franz Josef Land from the north-east, finally proving the existence of a deep sea basin to the north. Nansen wintered near Cape Jackson, Flora Island, a few miles from the point which Jackson had reached in 1895. On June 17, 1896, Nansen and Jackson met and the *Windward* brought Nansen home. The archipelago was further explored and used as a base for expeditions to the pole between 1897 and 1913.

Sept. 1, 1513.—Discovery of the Pacific

Vasco Nuñez de Balboa set out with a hundred Spaniards, among whom was Pizarro, and a thousand natives to cross the Isthmus of Panama. While in the town of Santa Maria de la Antigua del Darien, which he and Enciso had founded, he heard, from a native, accounts of the ocean beyond the mountains and of the gold of Peru. On Sept. 25 or 26, he reached the summit of the mountains and viewed the Pacific. Pizarro and two others had gone on in front, and one, Alonzo Martin, was the first European to embark on the newly found ocean, in St. Michael's Bay. On Sept. 29, Balboa reached the shore and took possession of the 'Great South Sea' for the Spanish monarch. He visited the Pearl Islands, once more heard of the gold of Peru, and returned in triumph to Darien in January 1514. He is said to have revisited the Pacific many times. He captured the Pearl Islands and prepared to conquer Peru, but through the jealousy of another official he was executed in 1517.

Lena Delta

...hev, reached 77° 29′ ...ape Chelyushkin. The ...t an expedition under his ...m Yakutsk, 900 miles from ...in 1735. After sailing down ...a delta, he reached the mouth ...nd wintered in some fur-hunters' ...ke up in Olonek Bay on Aug. 15, ...nischev proceeded north-west, almost ...ost northerly point on the coast. He ...ack by ice, but died of scurvy before ...ached the mouth of the Olonek River on ...his young wife, who had accompanied him, ... of scurvy.

...3, 1835.—The Russian Polar Seas

...Pachtussov reached Archangel after his second polar ...voyage, and shortly afterwards died from fatigue. His two expeditions were remarkable for the prudence and forethought which he displayed, the care which he showed for the health of his men, and notably for the wealth of astronomical, geodetical, meteorological, and tidal observations which he made. On his first journey, when wintering in southern Novaya Zemlya, in lat. 70° 36′ N., long. 59° 32′ E., meteorological observations were taken every second hour. Pachtussov was sent out in 1832 by citizens of Archangel to re-establish the sea-route to the Yenisei, to survey the east coast of Novaya Zemlya, and to hunt walrus in the latter place. On his first voyage he surveyed the east coast of Novaya Zemlya, and on his second Matotschkin Sound and the east coast of North Island, though his attempt to circumnavigate the latter failed. His second winter was spent on the south side of Matotschkin Sound, at the mouth of the River Tschirakina. Here he found the wreck of the vessel which Rossmuislov had been obliged to leave there in 1769 when he was on a voyage of exploration in Novaya Zemlya. The timber from the vessel was used by Pachtussov for building his winter house.

Societies and Academies

EDINBURGH

Royal Society, July 4.—**Eustace Barton-Wright and Alan McBain**: Studies in the physiology of the virus diseases of the potato. A comparison between the carbohydrate metabolism of normal and leaf-roll potatoes. An investigation into the formation of carbohydrates in healthy and leaf-roll potatoes at different times in the growing season. The nature of the translocatory sugars in healthy and diseased plants is also described and discussed.—**J. M. Robson**: Adrenaline and the œstrous cycle in the mouse. The subcutaneous injection of adrenaline hydrochloride into mature female mice inhibits the occurrence of œstrus; adrenaline also inhibits the development of sexual maturity when administered to immature female animals for prolonged periods. Vaginal cornification does not occur, and the growth of the vagina, uterus, and ovaries is less than in control animals. Evidence is presented suggesting that the action of the drug is not toxic in nature. Adrenaline does not interfere with the action of the α-hormone (œstrin) on the uterus and vagina. It does, however, interfere with the reactivity of the ovary to gonadotropic hormones (prepared from pregnancy urine).—**George Trapp**: The foliar endodermis of the Plantaginaceæ. The foliar endodermis is characteristic of the Plantaginaceæ. The Caspary strip is impervious to acid and basic dyes and probably also to ... The coincidence of mesophyll staining with endodermal absence or incompleteness in leaves of *P. arborescens* establishes this for acid dyes, while differential staining of Caspary strip region points to impermeability for basic dyes. Such a property is of value in the elaboration of root pressure. The aerial environment of the shoot reverses the direction of flow of solutes and renders functional interpretation impossible. The foliar endodermis is a feature of evolutionary inertia rather than of physiological necessity. —**A. G. Walker**: Relative co-ordinates. The elementary treatment of moving axes is extended to a general Riemannian space, a system of reference being defined at each point of a given curve. The elementary formulæ are generalised, and it is shown how the relative co-ordinates can be applied to a consideration of the geometry of the space in the neighbourhood of any given curve. As an example of application, the co-ordinates are used to discuss the kinematics of a rigid body in general relativity, the world line of one of the particles of the body being taken as the curve of reference. They also provide the formulæ used by Thomson in his work on rigid dynamics.—**John E. Mackenzie and Harry W. Melville**: The diffusion coefficients of bromine-hydrogen, bromine-nitrogen, bromine-oxygen, and bromine-carbon dioxide. The diffusion coefficients were measured by visual observation of the progress of diffusion of the highly coloured bromine vapour into a colourless gas contained in a long glass tube. The results obtained agree closely with those calculated from the theory of diffusion.

PARIS

Academy of Sciences, July 11 (vol. 195, pp. 85-192). —**Emmanuel Leclainche**: Notice on Bernhard Bang, *correspondant* for the Section of Rural Economy.—**Henri Lebesgue**: Notice on René Louis Baire, *correspondant* for the Section of Geometry.—**Maurice de Broglie and Louis Leprince-Ringuet**: The neutrons of boron excited by radium emanation. Whilst the rays from boron are absorbed at least as much by lead as by other bodies of equal thickness, the neutrons from boron pass much more easily through lead than through paraffin, the effect of 5 cm. of lead being scarcely perceptible.—**Léon Guillet, Marcel Ballay, and A. Le Thomas**: The influence of silicon on copper-nickel alloys containing small proportions of tin. Studies of a series of alloys with a fixed proportion of tin and increasing percentages of silicon, with special reference to the effect on the hardness at high temperatures.—**C. de La Vallée Poussin**: The properties of harmonic functions of two variables in an open area limited by particular lines.—**P. Vayssière**: Experimental observations on *Schistocerca gregaria*.—**Georges Giraud**: Certain operations on partial differentials of the parabolic type.—**A. Witt**: The stability of quasi-periodic movements.—**A. Lokchine**: The stability of a tube with curved axis.—**René Marty**: The calculation of helical springs loaded transversely.—**Emile Merlin**: The attraction between an ellipsoid and an external point.—**Sylvain Arend**: The normal anomaly and its rôle in two common astronomical applications.—**Y. Rocard**: The absorption of sound in tubes and acoustic mouthpieces. The nature of the wall of a tube through which sound is being propagated may cause loss through absorption. A modification of the classical equation (Lord Rayleigh, Webster) is suggested.—**Eligio Perucca**: The electrometer with semicircular sectors. This type of instrument is generally credited to Blondlot and Curie: it is pointed out that Morelli gave a complete theory of this instrument and described its practical realisation almost simultaneously with Blondlot and Curie.—**M. Pauthenier and R. Guillien**: The direct electrometric study of the limit charge of a conducting sphere in an ionised electrical field.—

Henri Abraham: The phenomena of synchronisation. A discussion of the conditions necessary for a wireless receiving apparatus to be in exact tune with the waves received.—**Pierre Girard** and **P. Abadie**: Experimental researches on the dispersion of polar liquids in the Hertzian field.—**P. Biquard** and **R. Lucas**: New optical properties of solids and liquids submitted to the action of ultra-sound waves.—**I. I. Agarbiceanu**: The intensities in the fluorescence spectrum of I_2.—**Joseph Giuntini**: α-Methoxy-β-hydroxysuccinic acid, its complex compounds with copper and their circular dichroism.—**B. Bogitch**: The separation of lead from zinc by the electrothermal method. For certain iron ores rich in lead and zinc the flotation method fails. Experiments with an electric furnace have given promising results.—**M. Bourguel, Mlle. B. Grédy**, and **L. Piaux**: Study of the *cis-trans* isomerism in the case of ethylene hydrocarbons of the formula $CH_3-CH=CH-R$. The eight hydrocarbons prepared have been studied from the point of view of the Raman spectrum.—**M. Haïssinsky**: The complex nature of the polonium ions.—**A. Lalande**: The turbidity surface of the system water-alcohol-ether at a low temperature.—**Georges Arditti**: The autoxidation of paraffin oil. A study of the amounts of fatty acids produced at a fixed temperature (130° C.) in the presence of various catalysts (Cu, Ni, CuO, NiO, Fe_2O_3).—**A. Travers** and **J. Aubert**: The variations of potential of electrolytic iron with the pH of the medium.—**Jean Cournot** and **Jean Challansonnet**: The action of molybdenum on the mechanical properties of grey cast iron. The mechanical properties of cast iron can be improved by the addition of molybdenum.—**Henri Fournier**: Attempts at stamping by the method of Siebel and Pomp.—**Francois Reymond** and **Tcheng Da-Tchang**: The reaction of precipitation by ammonia of the hydrofluoric acid solution of protactinium and of tantalum.—**A. Machebœuf, H. Cheftel**, and **J. Blass**: The colorimetric estimation of small quantities of lead introduced into food. The method outlined is suitable for determining quantities of lead between 0·15 mgm. and 0·25 mgm. to about 0·01 mgm.—**Jean Calvet**: The separation and determination of copper in the presence of aluminium by 8-hydroxyquinoline. Application to aluminium alloys.—**J. Guéron**: The slow hydrolysis of zinc acetate.—**Emilio Damour** and **Alexandre Nadel**: The diminution of the amount of iron in glass decolorised by selenium. In the decoloration of glass by selenium in presence of sodium chloride there is a partial volatilisation of the iron.—**R. Quelet**: The preparation of a chlormethyl derivative of p-bromanisol.—**Georges Corroy**: The Rhetian and the Hettangian in the east of the Paris basin.—**Fernand Daguin**: Stratigraphical observations on the region of Tissa (western Morocco).—**Edmond Saurin**: The Angaras to the east of southern Indo-China.—**J. Lombard** and **D. Schneegans**: The presence of the marine Eocene at Fouta (French Equatorial Africa).—**Paul Becquerel**: The dehiscence of the anther of the white lily.—**Antoine de Cugnac**: A new argument in favour of the hypothesis of a hybrid origin for *Bromus Gussonii*.—**André Dauphiné**: The properties of imbibition of collenchyma.—**Taboury**: The accidental presence of selenium in certain plants. It was shown in 1909 that selenium was present in the mineral springs at La Roche-Posay: selenium has now been found in *Sium latifolium* and in *Scrofularia aquatica* growing in the neighbourhood of these springs.—**Emile André** and **Kiawo Hou**: The lipoxydases of the seeds of *Glycine soja* and of *Phaseolus vulgaris*.—**Marc de Larambergue**: The absence of copulating apparatus in certain individuals of *Bullinus contortus*.—**Y. Le Grand**: The acuteness of the sense for variations of convergence.—**Neda Marinesco**: electric atmosphere o experimental proof of t on the flow of sap in the Study of the celluloses of A the Tunicata. These cellulos with cotton cellulose: chitin as forming part of the membr **W. S. Reich**: The synthetic p phosphoryl derivatives of the amino-a The considerable variations shown by of the maritime pine, *Pinus pinaster*, in power of the turpentine, and the relat of the rotatory power of the turpentine fro tree.—**Constantino Gorini**: The coagulation by *B. typhosus* and by other bacteria consid inactive towards milk.—**Pierre Lépine**: The s bility of the spermophile to exanthematic typhus.

CRACOW

Polish Academy of Science and Letters, April 11.—**K. Borsuk**: The isomorphism of functional spaces.—**W. J. Webber**: Certain properties of trigonometrical series presenting lacunæ. Note concerning a memoir of S. Banach.—**A. Jagielski**: The specific inductive capacity of liquid iodine. The S.I.C. of liquid iodine at 118° C. is 11·08, and increases with the temperature to 13 at 168° C.—**Wlad. Gorczyński**: A simple spectrograph and measurements of the absorption bands in the infra-red made in northern Africa in 1926–27.—**Wlad. Gorczyński** and **Ed. Stenz**: Atmospheric transmission in the ρ and Φ absorption bands of water vapour according to the spectrographic records of the solar spectrum made in Tunis in 1926–27.—**Ed. Stenz**: The absorption of water vapour in the solar infra-red, from spectrographic measurements made on the coast of the Mediterranean in 1931–32.—**Z. Kamecki**: Observations on the behaviour of the larvæ of Chrysopidæ and their faculty of finding their way by means of the senses.—**St. Skowron** and **T. Pawlas**: Observations concerning the action exerted by gonacrine on eggs and on the embryos of the rabbit.

VIENNA

Academy of Sciences, March 3.—**Gerhard Kirsch** and **Fritz Rieder**: Resonance of the beryllium nucleus. It has been recently shown by Curie and Joliot that the highly penetrating secondary radiation liberated from beryllium and boron by α-rays is able to set free, in substances containing hydrogen, a tertiary (H) radiation. The results of investigations on the tertiary radiation from various elements and of a consideration of the energy balance have led Chadwick to the conclusion that the penetrating secondary radiation is probably composed of neutrons of mass 1 and is not an electromagnetic wave radiation, as assumed by Curie and Joliot. Results are now given of experiments on the excitation of the secondary radiation in beryllium in relation to the energy of the exciting α-radiation, the tertiary H-radiation from hydrogen serving as indicator. These results appear to indicate the existence of resonance positions of the beryllium corresponding with residual ranges of the α-particles of 37 mm., 27 mm., and 15 mm. The assumption that the secondary radiation from beryllium comprises several components of varying hardness would furnish an explanation of the disagreement between absorption coefficient and maximum range of the tertiary protons noted by Curie and Joliot. The number of tertiary protons is extraordinarily high; if uniform distribution in space of the beryllium secondary radiation is assumed, the product of the efficiencies of the secondary and tertiary excitation process be about 3×10^{-8} for the resonance position co to the 27 mm. range.

...day, Sept. 1.

At 10 A.M.—Dr. W. H. Mills: "Some Aspects of Stereochemistry" (Presidential Address to Section B).

The Right Hon. Lord Rothschild: "The Pioneer Work of the Systematist" (Presidential Address to Section D).

Prof. H. J. Fleure: "The Geographical Study of Society and World Problems" (Presidential Address to Section E).

Mr. T. B. Ponsonby: "A System of Forestry for the British Isles" (Chairman's Address to the Department of Forestry (K*) of Section K).

Prof. R. G. White: "Sheep Farming, a Distinctive Feature of British Agriculture" (Presidential Address to Section M).

At 2 P.M.—Lieut.-Col. Sir David Prain: "The Conservation of Wild Life" (Presidential Address to the Conference of Delegates of Corresponding Societies).

Friday, Sept. 2.

At 10 A.M.—Prof. A. O. Rankine: "Some Aspects of Applied Geophysics" (Presidential Address to Section A).

Prof. R. B. Forrester: "Britain's Access to Overseas Markets" (Presidential Address to Section F).

Prof. Miles Walker: "The Call to the Engineer and Scientist" (Presidential Address to Section G).

Dr. D. Randall-MacIver: "The Place of Archæology as a Science, and some Practical Problems in its Development" (Presidential Address to Section H).

Mr. W. M. Heller: "The Advancement of Science in Schools: its Magnitude, Direction and Sense" (Presidential Address to Section L).

At 8 P.M.—Sir Arthur W. Hill: "Plant Products of the Empire in Relation to Human Needs" (Evening Discourse in the Co-operative Hall).

Monday, Sept. 5.

At 10 A.M.—Prof. P. G. H. Boswell: "The Contacts of Geology: the Ice Age and Early Man in Britain" (Presidential Address to Section C).

Prof. Beatrice Edgell: "Current Constructive Theories in Psychology" (Presidential Address to Section J).

Prof. J. H. Priestley: "The Growing Tree" (Presidential Address to Section K).

At 5.30 P.M.—Mr. H. E. Wimperis: "Speed in Flight" (Public Lecture in the Co-operative Hall).

At 8 P.M.—Sir Richard Gregory, Sir Harold B. Hartley, Mr. Donald Gray, Dr. W. W. Vaughan, Prof. W. W. Watts, Mr. W. M. Heller: Discussion on "The Place of Science in the Education of Boys and Girls up to Sixteen Years of Age".

Tuesday, Sept. 6.

At 8 P.M.—Mr. C. C. Paterson: "Uses of the Photoelectric Cell" (Evening Discourse in the Co-operative Hall).

The Contribution

THE return of the scene of its first m suggest interesting compar tion of science in 1831 and connexion it is not inappropria should occupy the presidential ch years ago the nation was still in the industrial revolution and the economi which followed the Napoleonic wars. I and inventions in mechanical science had found application in industry and were prod revolutionary changes in society. The whole stru ture of industry was being changed ; old industries hitherto carried on in the homes were being swept into the mills and factories and new industries had been created. The railway and steamship age was just opening, and was indeed fostered by some of the researches promoted by the Association. Faraday had already made the fundamental discovery which later bore fruit in the dynamo and all the myriad ramifications of the electrical industries.

Much of the unrest of this period was due, however, to the indifference to the social or human consequences with which mechanical and other scientific discoveries had been applied in industry. At the time when the British Association held its first meeting at York, the human aspects of the industrial revolution were just beginning to receive attention, and the movement which a decade later led to the passing of the Factory Acts was then being initiated by Lord Shaftesbury. There is perhaps nothing upon which scientific workers, whether engineers or not, are entitled to look back with more justifiable pride than the steady rise in the ethical standards of the industrial community wherever science has influenced its activities. In 1831 it is fair to say that little trace could be found of the scientific spirit in industry. The discoveries of science had been applied to industry with as much indifference to science as to humanity. During the following century, however, science brought the spirit of service into competition with the desire for private gain, and the perversion of the gifts of science to the exploitation of those least able look after themselves became less and less tol either to the industrial community or to a whole.

In this tendency, the tradition of the service of mankind should al advance

al of public service. ...ic spirit as involving ...y can be traced in the ...itution of Civil Engineers ...as in that of the Federated ...ng Societies. This change in ...stry has affected even economic ...has come to acknowledge that co- ...a nobler ideal than self-interest; and ... could easily be multiplied to show that ...try becomes more widely influenced by ... the obligation to subordinate self-seeking ...e common good becomes more widely acknow-...dged.

The transformation in the ethics of a large section of industry would alone be sufficient to explain the attention directed at the present time to the social consequences of the new industrial revolution. This new industrial revolution has emerged from that of the early nineteenth century so gradually that it is only in the last few years that its fundamental characteristic has been clearly perceived—the substitution of other powers for human physical effort as the working energy of the world's production. The acute reaction on employment of the immense increase in the productive capacity of mankind made possible by science has at last brought us to see that science has given us to-day a new kind of production. Power production embodies a profound and vital change in the relation of human labour to the processes and products of the world's work. Not merely in industry but also in agriculture and in transport, not merely with regard to manual labour but also in regard to clerical work, those greater resources of power and fuller control over the forces of Nature are enabling man to do more with less effort. The mechanical invasion of mankind is still only in its initial stages. More and more the function of labour becomes that of admitting power to the machine and manipulating power controls. The intelligence and responsibility hitherto known as skill in craftsmanship are either displaced or concentrated in a small central staff of experts.

These two significant facts—that output in pro-...tion has escaped from the limitations imposed ...man physical energy, and that actual pro-... to-day is indeed only a fraction of what it ...f the existing plant were worked to full ...rt altogether from the prospect of ...sation in the of... ...s well as in ...orced soci... ...que... ...nk...

in particular must face those consequences and be increasingly concerned with the moral and social results of their work. The future of civilisation itself depends less upon the increasing powers which scientific discoveries and their application have placed in the hands of men than upon the way in which these powers are used.

The existence of world-wide unemployment and poverty, the sinister shrinking of international trade, side by side with this greater productive power, more abundant crops, and fuller control over Nature have suggested to many that the old objection of the manual worker to machinery is not without foundation. It is useless for the scientific worker to provide the greater productive powers or even more effective ways of protecting crops unless society has an economic and social organisation which provides the appropriate seeds, fertilisers, tools, etc., and cultivators capable of understanding their use. This presupposes some developed system of industry, transport, distribution, and education, in which the cultivator and the inventor can both be fostered. The immense complexity of modern pure and applied science requires a corresponding complex social organisation.

When, however, we turn from the sphere of production to that of commerce and distribution, we enter a world of crude empiricism, secrecy, and mystification into which scientific method or principles have yet to permeate, and exact knowledge and its free interchange is almost totally absent. Our distributive and economic system remains on the basis of a pre-scientific era, wholly unadjusted to the change, and unable to bear the burdens placed upon it by this problem of new and almost incredible abundance. Adjustment is called for and can only be effective when the spirit and methods of science are freely applied in this sphere also, and it is recognised that the new powers involve the release of the general human life from Nature's old exaction of drudgery for a mere pittance. The release into an enlarged and enriched leisure for all men for general human culture would appear to be the only alternative to chronic unemployment.

It is thus not machinery that is at fault but the abuse of the powers which machinery has given to mankind, through mistakes in the economic and political sphere. The application of scientific methods in the fields of distribution and finance ha... scarcely bee...

to the far-flung factories and communications of the modern world. Machinery, the product of scientific knowledge, can only be controlled by greater knowledge, more widely understood and thoroughly applied. The mistakes in our economic, financial, and distributive systems can only be corrected by the application in these fields of the same scientific logic and strict submission to fact and impartial deduction which have given us the machines.

The contribution of science to these interwoven problems of leisure and distribution is not limited to the impartial examination of problems of finance and distribution. There are also required those qualities of mind which collectively make up the spirit of science—the readiness to face change or adopt new outlooks, theories, or hypotheses, the habits of accurate observation, collection, and arrangement of all relevant facts, the willingness to experiment, the power to formulate hypotheses and to use and test them as tools, not as creeds. These are qualities and habits which cannot be acquired or practised without sincerity of purpose, honesty of thought, and open-mindedness, and it is these, as well as the imagination which the scientific investigator must also possess, that are needed if we are to solve the problems of leisure and distribution. If it is true, as General Smuts pleads, that we need the cool, serious, gentle spirit of science in human affairs, and that the application of the true scientific spirit would make possible such a reign of justice and fair play on earth as only poets have dreamt of, it is also true that without the quality of imagination there can be no inspiring vision, no rising out of the common ruts of thought, either in science, in art, or in religion. The greatest men of science in every age have been men of vision possessed of imaginative powers which enabled their thoughts to pierce through the clouds of ignorance and uncertainty and discover some clue to the truth upon which their experimental genius and critical judgment could later be brought to bear.

There is much about us to suggest that the inspiration of such examples is one of the most important contributions that science can make to the solution of the common problems of humanity to-day. Not merely the technique of scientific method for ascertaining the relevant and undistorted facts upon which effective action must be based, not merely the spirit of adventure and the willingness to face change and to try new methods, essential as they are in the dynamic order of society which science has created, but also the vision of a new order of society in which man has quietly and confidently evolved the powers demanded of him for planning intelligently and co-operating efficiently on an international scale in the utilisation of the abundant resources of the world. As Prof. L. P. Jacks recently reminded us, " a race which emerged from the ignorance and brutality of barbaric ages is quite capable of emerging from mechanisation and standardisation, and will emerge if brave men stand to it ".

Scientific methods offer us a surer hope of the solution of our modern problems than the financial, economic, or commercial considerations which have so long dictated policy. It would be unwise, however, to assert that science alone would be sufficient. Science can assist in the discovery of the right ways for the use of the new powers with which it has endowed mankind, but the endeavours of science to make the world a better place to live in and to help men to be worthier of the splendid possibilities of life will be largely defeated unless there can be brought to bear the moral power which ensures the rightful use of those new powers. To the scientific mind and energy which patiently and impartially sorts out the facts of life there must be joined a sense of values, a moral purpose, and a vision of order and beauty competent to compel action upon the ascertained facts for the ordered development of mankind.

Overshadowed by the financial and political events of last autumn, the centenary meetings of the British Association did not receive their normal share of public attention, but the wise words of the presidential address may well come to be regarded as prophetic by many by whom at the time they were unheeded: " Among the human values thus created science ranks with art and religion. In its selfless pursuit of truth, in its vision of order and beauty, it partakes of the quality of both. More and more it is beginning to make a profound æsthetic and religious appeal to thinking people. . . . One of the gravest tasks before the human race will be to link up science with ethical values and thus to remove grave dangers affecting our future. . . . Science may be destined to become the most effective drive towards ethical values, and in that way to render its most priceless service." As the spiritual development of mankind comes once more in step with material progress, it will be possible for the combined moral, ethical, and scientific forces to build up a well-balanced civilisation from which disease, poverty, and war have been eliminated and men strive only to excel in the service they render, the contribution they offer to the common weal.

Mathematics and Astronomy of the Ancient Jewish Rabbis

Rabbinical Mathematics and Astronomy. By Dr. W. M. Feldman. Pp. xviii + 232. (London: M. L. Cailingold, 1931.) 10*s.* net.

WESTERN civilisation is largely based upon three influences emanating from Mediterranean shores—Hebrew, Greek, and Roman. While the legacy of Rome and the legacy of Greece have been gaining in appreciation in Western literature and thought, there has been a tendency to belittle the Hebraic influences. Things Jewish are almost always subject to exaggeration. There is a prevalent tendency (practically non-existent, however, in Great Britain) to attribute to Jewry the blame for every evil for which a more convenient scapegoat cannot be found, and this sometimes produces, in return, an exaggerated estimate of Jewish virtue and genius. Much that is written about Jews is either accusation or apology, a fact that has to be borne in mind in connexion with a publication like that which forms the basis of the present notice. Anybody writing about rabbinical science is tempted either to find merit where it does not exist or to overlook it where it does exist.

It is, therefore, all the more remarkable that Dr. Feldman, while being neither a professional rabbinical scholar nor a specialist in the exact sciences, has produced this volume, in which, on the whole, the tendency referred to is held in check. That the author has not been entirely successful in this regard indicates the difficulty of being completely objective. In some places it is also due to the author's limitations, both on the rabbinical and on the mathematical and astronomical sides.

Of what interest can it be to us to know how much mathematics and astronomy the Rabbis of the Talmud possessed? It is surely a fact that rabbinical influence upon the advance of the sciences was practically nil, and that, although the Jews in the Middle Ages were as important as the Arabs in the carrying on of the tradition of learning, especially in mathematics, astronomy, and medicine, nevertheless, this function was not due to talmudical influence, but to the Jewish love for learning from any source and for its own sake.

The answer is that it is of some importance, especially to Jews, but also to non-Jews, to understand clearly what have been the main currents of thought in Jewry during the various periods through which it has passed. The fact that the great Jewish thinkers of two thousand years ago are not known to have discovered any important scientific facts or devised any important scientific theories, and were, indeed, not even fully acquainted with what had been discovered by their Greek contemporaries; that, during the Middle Ages, the Jews shared with the Arabs the task of keeping scientific learning alive and fostering its growth; and that, in modern times, the Jews have occupied a place of ever-growing importance in scientific discovery—represents a significant piece of information that should throw light upon the nature of racial and national reaction to intellectual influences.

Dr. Feldman's book attempts to cater both for the scientific worker who knows nothing about the rabbinical life of the Jews and for the Jew who knows nothing about mathematics and astronomy. Perhaps he would have done better to quote frankly any mathematical and astronomical results needed for his book, without attempting to prove them. He sometimes gets lost in the mathematics, and in at least one place his knowledge of astronomy is faulty, namely, where he tries to explain Kepler's laws—which are, indeed, irrelevant to the main object of the book.

Dr. Feldman has also in several places departed from complete objectivity. He claims that, in rabbinic times, the Jewish calendar involved just such complicated calculations as he himself gives in his book. It is fairly certain that nothing of the kind really happened, and that the Rabbis of two thousand years ago used rule-of-thumb methods and very rough calculations in order to deal with the calendar. The Jewish calendar is, in fact, so rough an approximation that, while it represents a creditable performance for the Rabbis of the fourth century, it cannot, nevertheless, claim to have anything to do with evection and parallax, variation and secular acceleration.

The author has, however, avoided some of the traps into which other writers have fallen. He does not mistranslate a famous talmudical paragraph, in order to prove that the Rabbis of the Talmud believed in the Copernican system of the planets. He does not suggest that Rabbi Joshua in the first century A.D. knew about Halley's comet, although he claims that a periodic comet was known to this Rabbi. On the other hand, he strains the text in some places, especially when he refers to a 'tube' used by Rabbon Gamliel in the first century as being a telescope or an astrolabe. There is little in the talmudical text to indicate the nature of this tube, but there certainly is no reason to suppose any anticipation of Galileo. What little there is in the text suggests a round tube with one end open, the other end being provided

with a peephole. Probably the length of the tube, divided by the width of the open end, was used as the ratio of a distant object seen to occupy the diameter of the open end, divided by the size of the object. By using some standard object, like an average-sized palm tree, the tube could be adjusted for some fixed distance.

The general conclusion of the author is to assign some merit to the Rabbis in astronomy, but comparatively little in mathematics, except in so far as they were able to apply elementary mathematical theorems to various practical purposes. In a preface, Prof. R. A. Sampson says of the Jews " of the past ages " :

" they are interested in subtleties it is true, especially the subtleties of the Law, but not in those of Mathematics, nor of any natural science in which tradition counts for nothing. The regulation of the traditional Calendar forced upon them certain astronomical calculations which were competently performed, but the treatment, as any mathematician can see, is such as would lead to no advance."

This is probably a fair summing up of the situation, although it must be added that a more intimate study of the vast material available, and not dealt with in the present work, tends to prove that the Rabbis knew more and reasoned more scientifically than appears from Dr. Feldman's book. The book can be recommended to anybody who is interested in the scientific history of a unique people that has passed through unprecedented adventures and evolutions. S. B.

Pests of the Countryside

Beasts and Birds as Farm Pests. By Prof. James Ritchie. Pp. xii + 270. (Edinburgh and London : Oliver and Boyd, 1931.) 12*s.* 6*d.* net.

A THOROUGHLY useful book by an expert naturalist, dealing with mammals and birds as useful or injurious to British agricultural operations, and holding the scales fairly and evenly. Nature, if left alone, strikes a working balance between every animal and its natural enemies, but man's unconscious efforts usually load one scale. The nature of the agriculture is an important matter. Starlings, for example, " do great service in a pastoral country, in a corn-growing land they do great damage ". We hate them among our fruit, but it is possible that they, like many other ' pests ', are, on a balance, really beneficial on account of the vast numbers of slugs, snails, and insects they consume. Certainly we would suppose that stoats and weasels, so hated by the gamekeeper, by their destruction of rats, mice, and even rabbits, save stored corn and growing crops of many times the value of the occasional poultry that they kill.

The house sparrow is, of course, an unmitigated nuisance, and its annual damage is put at the very low figure of £8,000,000. Still worse are the rats, which, if estimated as equal in numbers to man in Great Britain and each doing damage of a penny a week, present a bill of £10,000,000—an estimate surely many times too small. Further, the author refers to brown rats as carriers of influenza, foot-and-mouth disease, and trichinosis, and the last disease and also dysentery may be carried to man. The black rat with its associated fleas are responsible for the spread of bubonic and pneumonic plagues. This may become a serious matter, for the black rat is a climber which might wander from house to house on our aerial networks, so that the new concrete building that clears our basements of brown rats would be of no avail. At any time this question of rats and mice might well become of great importance to public health, and it behoves us to inquire how far the provisions of the Rats and Mice (Destruction) Act of 1919 have been made effective in Great Britain. Assuredly, rats can only be lessened substantially in numbers by collective action.

Farmers may reduce most pests in their neighbourhood and even secure the desirable balance on their farms. Prof. Ritchie tells them how to combat their enemies—mammals interfering with stock, injurious to crops, wasting woodland, and destructive to stored grain. Birds are even more important and bulk larger in his consideration of the matter, all the evidence being summarised and critically and intelligently examined. This is just what is wanted, and the result is a most valuable work of reference and a guide to the practical man who uses his wits. It may be necessary to thin the stock of any bird in any ecological environment, but it is doubtful whether it would be wise policy to carry this out in any part of England to the extent to which it appears to be done in France.

The author coming from north of the Border, we naturally looked for a full account of that major pest, the American musk-rat, which is already widely distributed over Scotland and England. Here, as in the case of the grey squirrel and the little owl, the introduction was unintentional, and Prof. Ritchie truly states that " the worst pests in any country are, as a rule, creatures which have been introduced, accidentally or deliberately, from other places ". The musk-rat was introduced into Central Europe about 1905 and has become a major pest that exercises the government of every country

there. Its skins are now exported to North America and are no longer leaders in fashionable furs. Brought to England since the War, we now have scores of centres where the musk-rat breeds. They do not, perhaps, do much direct harm to the farmer's crops, but the prosperity of a large part of our agricultural population depends on the safety of the waterways, the banks of which they riddle with their burrowings. It is folly for the government of any civilised country not to use the knowledge that science has accumulated, and assuredly any body of competent zoologists could have foretold the years of unrelaxed efforts and vast expense to which we are now doomed (see "The Musk Rat Menace", by Martin A. C. Hinton, *Natural History Magazine*, April 1932, 177-184).

The Destructive Imported Animals Act, 1932, has come too late for the musk-rat, but we may inquire as to the competence of the machinery which it presumably sets up. Animals are so varied that no civil servant can know all, and it might be wise for any Government department concerned with animal importations, for pleasure or profit, to ask advice of the experts in the British Museum and of animal science as represented in the Royal Society. We are sure that neither body would neglect to seek the opinions of the author of the valuable volume now before us.

Quantum Theory.

(1) *The Theory of Groups and Quantum Mechanics.* By Prof. Hermann Weyl. Translated from the second (revised) German edition by Prof. H. P. Robertson. Pp. xxii + 422. (London: Methuen and Co., Ltd., 1931.) 21*s*. net.

(2) *L'Atome de Bohr: la mécanique analytique et les quanta, les spectres de multiplets.* Par Prof. Léon Brillouin. (Recueil des Conférences-Rapports de documentation sur la Physique.) La théorie des quanta. Deuxième édition. Pp. 363. (Paris: Les Presses universitaires de France, 1931.) 100 francs.

(3) *The Physical Significance of the Quantum Theory.* By Prof. F. A. Lindemann. Pp. vii + 148. (Oxford: Clarendon Press; London: Oxford University Press, 1932.) 7*s*. 6*d*. net.

(1) AN English edition of Prof. H. Weyl's well-known book is very welcome; the book remains a difficult one to read, but to anyone with an imperfect knowledge of German the task will be considerably lightened by the translation. The translation has been made from the second German edition, which differs from the first in that certain chapters, notably Chap. v., which originally were more condensed and harder to understand than the rest of the book, have been rewritten in a simpler way. Also in the third chapter, in which group theory is first introduced, an example, namely, the Clebsch-Gordan series, is given of a group and of its reduction. Another welcome addition is a discussion of the Heisenberg-Pauli theory of the quantisation of the radiation field, which has appeared since the first edition of Prof. Weyl's book.

It has been rumoured, as Prof. Weyl admits in his introduction, that the 'group pest' is disappearing from theoretical physics. It is certainly true that, thanks to the work of Slater, Bloch, and others, the chief applications of quantum theory to spectroscopy and chemistry can be understood without mastering the notation of group theory. It is probable that group theory will in the future prove more useful in other fields, as, for example, in the search for a satisfactory synthesis of relativity and quantum mechanics. To anyone hoping to embark on such a task, or wishing to understand the work already done in this field, Prof. Weyl's book does not need recommendation.

(2) To the future student of the history of theoretical physics, Prof. Brillouin's book will be invaluable; for it expounds, with the lucidity and elegance that one expects from a Frenchman, the Bohr-Sommerfeld theory of the quantisation of orbits, as it was in 1924, before its methods finally gave place to those of the new mechanics. Some 140 pages are devoted to relativity, electromagnetism, and general dynamical theory; the Bohr-Sommerfeld theory occupies the rest of the book.

The book is theoretical, there being no description of experiments. Such matters as Zeeman effect, multiplets, relativity correction, and spinning electron are dealt with. There is a detailed discussion of the theory of penetrating orbits, showing the very rough agreement with experiment that could be obtained with the old theory. Nothing but praise can be given to the way in which the subject matter is presented; the reviewer would only question whether it was worth while to write such a detailed account of a physical theory which is now largely superseded.

(3) Prof. Lindemann's book is an attempt to show that some results of the wave mechanics, such as the exclusion principle and the quantisation of energy, are consequences of the Heisenberg uncertainty principle and of the resultant failure of the spatio-temporal description of physical phenomena. In the opinion of the reviewer, the attempt is not successful, because, although the author makes

it appear plausible that some kind of quantisation results from the uncertainty principle, he does not attempt to deduce Schrödinger's equation. It is surely of little use to attempt to explain such a phenomenon as quantisation, unless one can shed light on the origins of the equation from which the exact values of the energy levels can be deduced. N. F. M.

Short Reviews

A Handbook of Child Psychology. By John E. Anderson, Charlotte Bühler, Anna Freud, Arnold Gesell, Florence Goodenough, Leta S. Hollingworth, Susan Isaacs, Harold Ellis Jones, Mary Cover Jones, Vernon Jones, C. W. Kimmins, Heinrich Klüver, Kurt Lewin, Helen Marshall, Dorothea McCarthy, Margaret Mead, Joseph Peterson, Jean Piaget, Rudolf Pintner, Lewis M. Terman, Beth L. Wellman, Helen T. Woolley. Edited by Carl Murchison. (The International University Series in Psychology.) Pp. xiii + 711. (Worcester, Mass.: Clark University Press; London: Oxford University Press, 1931.) 22*s.* 6*d.* net.

THE subject of child psychology is really a very old one, although the interest displayed in it by so many psychologists, medical men and lay persons, is very largely a post-War phenomenon. Prof. Carl Murchison presents us with an extremely varied and well-balanced selection of papers by authorities on problems of child psychology the world over. In his preface he mentions the omission of a chapter on the delinquent child and calls for discussion. It is admittedly difficult to deal adequately with delinquency in children in a single chapter, but we think that the subject belongs very much more to the realm of psychology than to that of sociology. One has only to read Burt's " Young Delinquent " to realise the wide ramifications of delinquency when regarded as a psychological problem. We would very much welcome two or even three chapters devoted to delinquency in the next edition. The chapter devoted to eating, sleeping, and elimination is well done but seems rather long. The chapters by such authorities as Piaget and Bühler need no recommendation, since they are typical of the high standard one expects.

Mechanical Testing: a Treatise in Two Volumes. By R. G. Batson and J. H. Hyde. (The Directly-Useful Technical Series.) Vol. 1: *Testing of Materials of Construction.* Second and enlarged edition. Pp. xv + 465 + 68 plates. (London: Chapman and Hall, Ltd., 1931.) 21*s.* net.
